**Important Notices and Disclaimers:** Publication of this handbook is for the purpose of circulating information and opinion among those concerned for fire and electrical safety and related subjects. While every effort has been made to achieve a work of high quality, neither the NFPA® nor the contributors to this handbook guarantee the accuracy or completeness of or assume any liability in connection with the information and opinions contained in this handbook. The NFPA and the contributors shall in no event be liable for any personal injury, property, or other damages of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this handbook.

This handbook is published with the understanding that the NFPA and the contributors to this handbook are supplying information and opinion but are not attempting to render engineering or other professional services. If such services are required, the assistance of an appropriate professional should be sought.

NFPA codes, standards, recommended practices, and guides (“NFPA Documents”), including the NFPA Document that is the subject of this handbook, are made available for use subject to Important Notices and Legal Disclaimers, which appear at the end of this handbook and can also be viewed at [www.nfpa.org/disclaimers](http://www.nfpa.org/disclaimers).

**Notice Concerning Code Interpretations:** This twelfth edition of the *National Electrical Code® Handbook* is based on the 2011 edition of *NFPA 70®*. All NFPA codes, standards, recommended practices, and guides (“NFPA Documents”) are developed in accordance with the published procedures of the NFPA by technical committees comprised of volunteers drawn from a broad array of relevant interests. The handbook contains the complete text of *NFPA 70* and any applicable Formal Interpretations issued by the NFPA. This NFPA Document is accompanied by explanatory commentary and other supplementary materials.

The commentary and supplementary materials in this handbook are not a part of the NFPA Document and do not constitute Formal Interpretations of the NFPA (which can be obtained only through requests processed by the responsible technical committees in accordance with the published procedures of the NFPA). The commentary and supplementary materials, therefore, solely reflect the personal opinions of the editor or other contributors and do not necessarily represent the official position of the NFPA or its technical committees.

# Dedication

The editors of the *National Electrical Code Handbook* proudly dedicate the 2011 edition to James W. Carpenter. Jim has been a dedicated member of the National Electrical Code Committees since 1987, representing the International Association of Electrical Inspectors. He has served as a member of CMP 3 and CMP 2 and as chair of CMP 2 from 1992–2002. He became a member of the NEC Technical Correlating Committee in January 2002 and was appointed chair in July 2002. In both of these chair roles, he has facilitated process improvements that have increased the operating efficiency of the committees. He is also a member of the NFPA Standards Council, the UL Electrical Council, and the Electrical Code Coalition. During his tenure on the NEC Committees, he was an electrical inspector and chief electrical inspector and engineer for the state of North Carolina. Most recently, he was chief executive officer and executive director of the International Association of Electrical Inspectors. We commend him for his leadership on the last three editions of the *NEC*. His legacy will be one of improved electrical safety worldwide.

## Annexes

Informative Annex A	Product Safety Standards	1327
Informative Annex B	Application Information for Ampacity Calculation	1333
Informative Annex C	Conduit and Tubing Fill Tables for Conductors and Fixture Wires of the Same Size	1349
Informative Annex D	Examples	1413
Informative Annex E	Types of Construction	1425
Informative Annex F	Availability and Reliability for Critical Operations Power Systems; and Development and Implementation of Functional Performance Tests (FPTs) for Critical Operations Power Systems	1429
Informative Annex G	Supervisory Control and Data Acquisition (SCADA)	1433
Informative Annex H	Administration and Enforcement	1435
Informative Annex I	Recommended Tightening Torque Tables from UL Standard 486A-B	1443

## Index 1445

## Important Notices and Legal Disclaimer 1498

# Preface

This handbook contains the 52nd edition of the *National Electrical Code*®. Nearly 114 years have passed since those cold days of March 18-19, 1896, when a group of 23 persons representing a wide variety of organizations met at the headquarters of the American Society of Mechanical Engineers in New York City. Their purpose was to develop a national code of rules for electrical construction and operation. (It is interesting to note that this meeting took place a mere 17 years after the invention of the incandescent light bulb.) This attempt was not the first to establish consistent rules for electrical installations, but it was the first national effort. The number of electrical fires was increasing, and the need for standardization was becoming urgent. By 1881, one insurer had reported electrical fires in 23 of the 65 insured textile mills in New England.

The major problem was the lack of an authoritative, nationwide electrical installation standard. As one of the early participants noted, “We were without standards and inspectors, while manufacturers were without experience and knowledge of real installation needs. The workmen frequently created the standards as they worked, and rarely did two men think and work alike.”

By 1895, five electrical installation codes had come into use in the United States, causing considerable controversy and confusion. The manufacture of products that met the requirements of all five codes was difficult, so something had to be done to develop a single, national code. The committee that met in 1896 recognized that the five existing codes should be used collectively as the basis for the new code. In the first known instance of international harmonization, the group also referred to the German code, the code of the British Board of Trade, and the Phoenix Rules of England. The importance of industry consensus was immediately recognized; before the committee met again in 1897, the new code was reviewed by 1200 individuals in the United States and Europe. Shortly thereafter, the first standardized U.S. electrical code, the *National Electrical Code*, was published.

The *National Electrical Code* has become the most widely adopted code in the United States. It is the installation code used in all 50 states and all U.S. territories. Moreover, it has grown well beyond the borders of the United States and is now used in numerous other countries. Because the *Code* is a living document, constantly changing to reflect changes in technology, its use continues to grow.

Some things have not changed. The *National Electrical Code* continues to offer an open-consensus process. Anyone can submit a proposal for change or a public comment, and all proposals and comments are subject to a rigorous public review process. The *NEC*® still provides the best technical information, ensuring the practical safeguarding of persons and property from the hazards arising from the use of electricity.

Throughout its history, the National Electrical Code Committee has been guided by giants in the electrical industry. The names are too numerous to mention. Certainly the first chairman, William J. Hammer, should be applauded for providing the leadership necessary to get the *Code* started. More recently, the *Code* has been chaired by outstanding leaders such as Richard L. Loyd, Richard W. Osborne, Richard G. Biermann, D. Harold Ware, and James W. Carpenter. Each of these men has devoted many years to the National Electrical Code Committee.

The editors also wish to note the passing of some long-term committee members who made numerous contributions to the *National Electrical Code*: George W. Flach, Tim Owens, and Andy White.

The editors have conferred closely with members of the National Electrical Code Committee in developing the revisions incorporated into the 2011 edition of the *Code*. The assistance and cooperation of code-making panel chairs and various committee members are herein gratefully acknowledged.

This edition of the *NEC Handbook* would not have been possible without the invaluable technical assistance of Mark Cloutier and Lee F. Richardson, senior electrical engineers at NFPA. Their contributions are greatly appreciated.

The editors acknowledge with thanks the manufacturers and their representatives who generously supplied photographs, drawings, and data upon request. Special thanks also to the editors of and contributors to past editions. Their work provided an excellent foundation on which to build.

The editors express special thanks to Khela Thorne, Jen Harvey, Irene Herlihy, and Marla Marek for their long hours and extraordinary effort in attending to all of the editorial details that we technical types often overlook. We also thank Cheryl Langway and Josiane Domenici for their contributions to

the design and artwork and for obtaining the necessary permissions. Special thanks are also due to Debra Rose, the project manager who kept this project on track and handled all the important logistical details. Without the efforts of Debra, Khela, Jen, Irene, Marla, Cheryl, and Josiane, this new and improved edition of the *NEC Handbook* would not have been possible.

We also wish to thank the electrical support staff: Carol Henderson, Mary Warren-Pilson, and Kimberly Shea, along with their leader, Jean O'Connor, for their support on this project. The editors express special appreciation to James W. Carpenter, and new IAEI CEO/executive director David Clements, International Association of Electrical Inspectors, for their contribution of a significant number of outstanding photographs for this edition of the handbook.

The editors express their sincere appreciation to Mark Hilbert, Michael Johnston, Steve Kieffer, David Kendall, Alan Manche, James Pauley, Vincent Saporita, Steve Terry, and John C. Wiles for photographs and special help on specific articles. Finally, we also thank the following for contributing photographs and graphics for this edition:

3M Co., Electrical Markets Division	Flatwire Technologies, a division of Southwire®	Noel Williams
AFC Cable Systems, Inc.	Fluke Corp.	O-Z/Gedney, a Division of EGS Electrical Group
Ajax Tocco Magnethermic, Park Ohio Industries	GE Energy	Pepperl and Fuchs, Inc.
Alcoa Inc.	General Electric Co.	Protectowire Fire Systems
Appleton Electric Co., EGS Electrical Group	H. H. Robertson Floor Systems	Quazite® (Hubbell Lenoir City, Inc.)
ASME - American Society of Mechanical Engineers	Hubbell Wiring Device - Kellems	RELOC® Wiring Solutions, an Acuity Brands Company
Blue Diamond Industries, LLC	Hubbell RACO	RSCC Wire & Cable, LLC

### Notice to Users

Throughout this handbook, the commentary text is overprinted with a color tint panel to distinguish it from the *Code* text. Note that the commentary is not part of the *Code* and therefore is not enforceable.

# About the Editors

## **Mark W. Earley, P.E.**

Mark W. Earley, P.E., is Chief Electrical Engineer at NFPA. He has served as Secretary of the *NEC* since 1989 and is the co-author of NFPA's reference book, *Electrical Installations in Hazardous Locations*. He has also served as an editor for the *NFPA 70E Electrical Safety in the Workplace Handbook*. Prior to joining NFPA, he worked as an electrical engineer at Factory Mutual Research Corporation. Additionally, he has served on several of NFPA's electrical committees and *NEC* code-making panels. Mr. Earley is a registered professional engineer (licensed in Rhode Island) and a member of International Association of Electrical Inspectors (IAEI), IEEE, the Society of Fire Protection Engineers (SFPE), the Automatic Fire Alarm Association (AFAA), the UL Electrical Council, U.S. National Committee on the International Electrotechnical Commission, and the Canadian Electrical Code, Part 1 Committee.

## **Jeffrey S. Sargent**

Jeffrey S. Sargent is Senior Electrical Specialist at NFPA. He serves as staff liaison to several NFPA technical committees, including Electrical Safety in the Workplace (NFPA 70E), Electrical Equipment Maintenance (NFPA 70B), and Emergency Power Supplies (NFPA 110 and 111). He is the former executive secretary to the NFPA Electrical Section and is the co-author of the *Electrical Inspection Manual with Checklists* and *NEC Q and A*, as well as being a regular contributor to *necplus*®, which is NFPA's official on-line subscription service supporting the *National Electrical Code* and *NFPA 70E*. Prior to joining NFPA in 1997, he served as an electrical inspector in state and municipal positions and as an instructor in the electrical program at the New Hampshire Technical College. Mr. Sargent is a licensed master electrician and a member of IAEI.

# About the Contributors

## **Christopher D. Coache**

Christopher D. Coache is Senior Electrical Engineer at NFPA. Prior to joining the NFPA in 2008, he was employed for more than 20 years as an electrical engineer at Factory Mutual Research Corporation and as a compliance engineer in the information technology industry. Additionally, he has participated in IEC and ISA standards development. He serves as the staff liaison to NFPA 73, *Electrical Inspection Code for Existing Dwellings*. Mr. Coache is a member of the IAEI and IEEE.

## **Richard J. Roux**

Richard J. Roux, SET, FAI, FAM, is Senior Electrical Specialist at NFPA. He serves as staff liaison to NFPA 780, 79, 790, and 791. He also provides technical support for *NFPA 72*®, *National Fire Alarm and Signaling Code*. He joined NFPA after 25 years in the fire detection systems field. Mr. Roux is NICET Level IV certified and IMSA Level II certified in both Municipal Fire Alarm and Interior Fire Alarm. He is a member of SFPE, IMSA, and AFAA. He is also co-author of the *NFPA Pocket Guide to Fire Alarm System Installation* and co-editor of the *National Fire Alarm and Signaling Code Handbook*.

## **In Memoriam**

It is with profound regret that we note the passing of our friend George W. Flach. George was an industry icon. Over time, he served the electrical industry in a variety of roles. He was chief electrical inspector for the city of New Orleans, a long-time member and past chair of CMP 15, a contributor to IAEI news, and past international president of IAEI, to name a few. Most recently, he served as member emeritus on CMP 13. He received his BSEE from Tulane University in 1949

and was a registered professional engineer. George was also part of the “greatest generation,” having served as a bomber pilot during World War II.

Many of us knew George best from his many years on the IAEI circuit, where he was always willing to share his knowledge. He was a Gold Roadrunner and a member of the NEC Quarter Century Club. At the 2010 NFPA Conference and Exposition, George was posthumously awarded the NFPA Standards Medal for contributing unselfishly to the development of NFPA codes and standards for more than thirty-six years, and for an enduring commitment to the NFPA and the cause of fire and life safety worldwide.

### 90.1 Purpose

**(A) Practical Safeguarding.** The purpose of this *Code* is the practical safeguarding of persons and property from hazards arising from the use of electricity.

The *National Electrical Code*® (*NEC*®) is prepared by the National Electrical Code Committee, which consists of a Technical Correlating Committee and 19 code-making panels. The code-making panels have specific subject responsibility within the *Code*. The scope of the National Electrical Code Committee is as follows:

This committee shall have primary responsibility for documents on minimizing the risk of electricity as a source of electric shock and as a potential ignition source of fires and explosions. It shall also be responsible for text to minimize the propagation of fire and explosions due to electrical installations.

In addition to its overall responsibility for the *National Electrical Code*, the Technical Correlating Committee is responsible for NFPA 70A, *National Electrical Code*® *Requirements for One- and Two-Family Dwellings*, and for correlation of the following documents:

1. NFPA 70B, *Recommended Practice for Electrical Equipment Maintenance*
2. NFPA 70E®, *Standard for Electrical Safety in the Workplace*®
3. NFPA 73, *Standard for Electrical Inspection for Existing Dwellings*
4. NFPA 79, *Electrical Standard for Industrial Machinery*
5. NFPA 110, *Standard for Emergency and Standby Power Systems*
6. NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*

**(B) Adequacy.** This *Code* contains provisions that are considered necessary for safety. Compliance therewith and proper maintenance results in an installation that is essentially free from hazard but not necessarily efficient, convenient, or adequate for good service or future expansion of electrical use.

Informational Note: Hazards often occur because of overloading of wiring systems by methods or usage not in conformity with this *Code*. This occurs because initial wiring did not provide for increases in the use of electricity. An initial adequate installation and reasonable provisions for system changes provide for future increases in the use of electricity.

Consideration should always be given to future expansion of the electrical system. Future expansion might be unlikely in some occupancies, but for others it is wise to plan an initial installation, comprised of service-entrance conductors and

equipment, feeder conductors, and panelboards, that allows for future additions, alterations, or designs.

**(C) Intention.** This *Code* is not intended as a design specification or an instruction manual for untrained persons.

The *NEC* is intended for use by capable engineers and electrical contractors in the design and/or installation of electrical equipment; by inspection authorities exercising legal jurisdiction over electrical installations; by property insurance inspectors; by qualified industrial, commercial, and residential electricians; and by instructors of electrical apprentices or students.

**(D) Relation to Other International Standards.** The requirements in this *Code* address the fundamental principles of protection for safety contained in Section 131 of International Electrotechnical Commission Standard 60364-1, *Electrical Installations of Buildings*.

Informational Note: IEC 60364-1, Section 131, contains fundamental principles of protection for safety that encompass protection against electric shock, protection against thermal effects, protection against overcurrent, protection against fault currents, and protection against overvoltage. All of these potential hazards are addressed by the requirements in this *Code*.

In addition to being the most widely adopted code for the built environment in the United States, the *NEC* is also adopted and used extensively in many foreign countries. Section 90.1(D) makes it clear that the *NEC* is compatible with international safety principles, and it addresses the fact that installations meeting the requirements of the *NEC* are also in compliance with the fundamental principles outlined in IEC 60364-1, *Electrical Installations of Buildings*, Section 131. Countries that do not have formalized rules for electrical installations can adopt the *NEC* and by so doing be fully compatible with the safety principles of IEC 60364-1, Section 131. Section 90.1(D) continues to promote acceptance and adoption of the *NEC* internationally.

The *NEC* is an essential part of the safety system of the Americas, and its future will be enhanced by increased international acceptance.

## 90.2 Scope

**(A) Covered.** This *Code* covers the installation of electrical conductors, equipment, and raceways; signaling and communications conductors, equipment, and raceways; and optical fiber cables and raceways for the following:

- (1) Public and private premises, including buildings, structures, mobile homes, recreational vehicles, and floating buildings
- (2) Yards, lots, parking lots, carnivals, and industrial substations

Requirements for locations such as these are found throughout the *Code*. Specific items such as outside feeders and branch circuits can be found in Article 225, grounding in Article 250, surge arresters in Article 280, switches in Article 404, outside lighting in Article 410, transformers in Article 450, and carnivals in Article 525.

- (3) Installations of conductors and equipment that connect to the supply of electricity

Often, but not always, the source of supply of electricity is the serving electric utility. The point of connection from a premises wiring system to a serving electric utility system is, by definition, referred to as the *service point*. The conductors on the premises side of the service point are, by definition, referred to as *service conductors*. (These definitions are found in Article 100.) The requirements for service conductors as well as for service-related equipment are found in Article 230. Article 230 applies only where the source of supply of electricity is from a utility.

Where the source of supply of electricity is not the serving electric utility, the source may be a generator, a battery system, a solar photovoltaic system, a fuel cell, a wind turbine, or a combination of those sources. Requirements for such sources of supply are found in Article 445 and Articles 700 through 702 for generators, Article 480 for storage batteries, Article 690 for solar photovoltaic systems, Article 692 for fuel cells, and Article 694 for small wind electric systems. The associated delivery wiring requirements are found in Chapters 2 and 3 (except Article 230) and in Articles 700 through 702 for emergency, legally required, and optional standby power system circuits. Where the source of supply includes utility source(s) in combination with alternate energy sources, Article 705, Interconnected Electric Power Production Sources, also applies.

- (4) Installations used by the electric utility, such as office buildings, warehouses, garages, machine shops, and recreational buildings, that are not an integral part of a generating plant, substation, or control center.

Section 90.2(A) provides order and clarity concerning the portions of electric utility facilities covered by the *NEC*. [See 90.2(B) and the related commentary for information on

facilities and specific lighting not covered by the *NEC*.] Exhibit 90.1 illustrates the distinction between electric utility facilities to which the *NEC* does and does not apply. The electrical equipment in the generating plant is not governed by the rules of the *NEC*. The warehouse is a typical commercial facility in which the electrical equipment would be governed by the rules of the *NEC*, regardless of its ownership. Office buildings and warehouses of electric utilities are similar from a functional standpoint to similar facilities owned by other commercial entities.

Industrial and multibuilding complexes and campus-style wiring often include substations and other installations that employ construction and wiring similar to those of electric utility installations. Because these installations are on the load side of the service point, they are clearly within the purview of the *NEC*. At an increasing number of industrial, institutional, and other campus-style distribution systems, the service point is at an owner-maintained substation and the conductors extending from that substation to the campus facilities are feeders (see definition in Article 100). The *NEC*

**EXHIBIT 90.1** Typical electric utility complexes showing examples of facilities covered and not covered by the requirements of the *NEC*. The top photo is of a conventional generating plant, which is governed by the *National Electrical Safety Code*®. The bottom photo is of a support facility that is subject to *NEC* requirements.

provides rules to cover these distribution systems. For example, one relatively recent addition to the *NEC* is the overhead clearance requirements for outside conductors operating at over 600 volts in 225.60 and 225.61. This edition of the *NEC* includes new requirements in Article 399 on outdoor, overhead conductors for systems operating at over 600 volts. These overhead conductor and live parts clearance requirements in the *NEC* correlate with those in ANSI C2, *National Electrical Safety Code*® (*NESC*), for overhead conductors under the control of an electric utility.

**(B) Not Covered.** This *Code* does not cover the following:

- (1) Installations in ships, watercraft other than floating buildings, railway rolling stock, aircraft, or automotive vehicles other than mobile homes and recreational vehicles

Informational Note: Although the scope of this *Code* indicates that the *Code* does not cover installations in ships, portions of this *Code* are incorporated by reference into Title 46, *Code of Federal Regulations*, Parts 110–113.

The *NEC* does not specifically cover shipboard wiring. However, Title 46 of the *Code of Federal Regulations*, Parts 110–113, does contain many specific *NEC*-referenced requirements. These requirements, which originated in the *NEC*, are enforced by the U.S. Coast Guard for shipboard applications. Installation requirements for floating buildings are covered in Article 553 of the *NEC*.

- (2) Installations underground in mines and self-propelled mobile surface mining machinery and its attendant electrical trailing cable
- (3) Installations of railways for generation, transformation, transmission, or distribution of power used exclusively for operation of rolling stock or installations used exclusively for signaling and communications purposes
- (4) Installations of communications equipment under the exclusive control of communications utilities located outdoors or in building spaces used exclusively for such installations
- (5) Installations under the exclusive control of an electric utility where such installations
  - a. Consist of service drops or service laterals, and associated metering, or
  - b. Are on property owned or leased by the electric utility for the purpose of communications, metering, generation, control, transformation, transmission, or distribution of electric energy, or
  - c. Are located in legally established easements or rights-of-way, or

- d. Are located by other written agreements either designated by or recognized by public service commissions, utility commissions, or other regulatory agencies having jurisdiction for such installations. These written agreements shall be limited to installations for the purpose of communications, metering, generation, control, transformation, transmission, or distribution of electric energy where legally established easements or rights-of-way cannot be obtained. These installations shall be limited to federal lands, native American reservations through the U.S. Department of the Interior Bureau of Indian Affairs, military bases, lands controlled by port authorities and state agencies and departments, and lands owned by railroads.

Informational Note to (4) and (5): Examples of utilities may include those entities that are typically designated or recognized by governmental law or regulation by public service/utility commissions and that install, operate, and maintain electric supply (such as generation, transmission, or distribution systems) or communications systems (such as telephone, CATV, Internet, satellite, or data services). Utilities may be subject to compliance with codes and standards covering their regulated activities as adopted under governmental law or regulation. Additional information can be found through consultation with the appropriate governmental bodies, such as state regulatory commissions, the Federal Energy Regulatory Commission, and the Federal Communications Commission.

Section 90.2(B)(5) is not intended to exclude the *NEC* as an installation regulatory document. The *NEC* is fully capable of being utilized for electrical installations in most cases, and 90.2(B)(5) does not pertain to areas where portions of the *NEC* could not be used. Rather, 90.2(B)(5) lists specific areas where the nature of the installation requires specialized rules or where other installation rules, standards, and guidelines have been developed for specific uses and industries. For example, the electric utility industry uses the *NESC* as its primary requirement in the generation, transmission, distribution, and metering of electric energy. See Exhibit 90.1 for examples of electric utility facilities that may or may not be covered by the *Code*. In most cases, utility owned installations will be on legally established easements or rights of way. Easements or rights of way may not be available on federally owned lands, Native American reservations, military bases, lands controlled by port authorities or state agencies or departments, and lands owned by railroads. In these limited applications, a written agreement complying with this section may be used to establish the extent of the utility installation.

**(C) Special Permission.** The authority having jurisdiction for enforcing this *Code* may grant exception for the

installation of conductors and equipment that are not under the exclusive control of the electric utilities and are used to connect the electric utility supply system to the **service conductors** of the premises served, provided such installations are outside a building or **structure**, or terminate inside nearest the point of entrance of the service conductors.

### 90.3 Code Arrangement

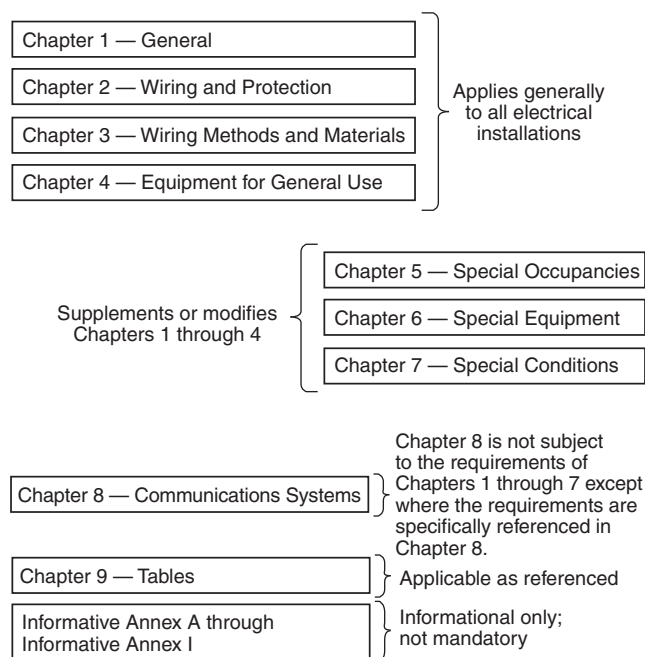

This *Code* is divided into the introduction and nine chapters, as shown in Figure 90.3. Chapters 1, 2, 3, and 4 apply generally; Chapters 5, 6, and 7 apply to special occupancies, special equipment, or other special conditions. These latter chapters supplement or modify the general rules. Chapters 1 through 4 apply except as amended by Chapters 5, 6, and 7 for the particular conditions.

Chapter 8 covers communications systems and is not subject to the requirements of Chapters 1 through 7 except where the requirements are specifically referenced in Chapter 8.

Chapter 9 consists of tables that are applicable as referenced.

Informative annexes are not part of the requirements of this *Code* but are included for informational purposes only.

The reference to “the introduction” in 90.3 is intended to include Article 90 in the application of the *Code*. Chapters 1 through 4 apply generally, except as amended or specifically referenced in Chapters 5, 6, and 7 (Articles 500 through

**FIGURE 90.3** Code Arrangement.

770). For example, 300.22 (Chapter 3) is modified by 725.3(C) and 760.3(B) and is specifically referenced in 800.24, 800.13(B), 800.113(C), and 830.3(B). Figure 90.3 is a graphic explanation of the *NEC* arrangement.

### 90.4 Enforcement

This *Code* is intended to be suitable for mandatory application by governmental bodies that exercise legal jurisdiction over electrical installations, including signaling and communications systems, and for use by insurance inspectors. The authority having jurisdiction for enforcement of the *Code* has the responsibility for making interpretations of the rules, for deciding on the approval of equipment and materials, and for granting the special permission contemplated in a number of the rules.

Some localities do not adopt the *NEC*, but even in those localities, installations that comply with the current *Code* are prima facie evidence that the electrical installation is safe.

Section 90.4 advises that all materials and equipment used under the requirements of the *Code* are subject to the approval of the authority having jurisdiction. The text of 90.7, 110.2, and 110.3, along with the definitions of the terms *approved*, *identified (as applied to equipment)*, *labeled*, and *listed*, is intended to provide a basis for the authority having jurisdiction to make the judgments that fall within that particular area of responsibility.

The phrase “including signaling and communication systems” emphasizes that, indeed, these systems are also subject to enforcement.

By special permission, the authority having jurisdiction may waive specific requirements in this *Code* or permit alternative methods where it is assured that equivalent objectives can be achieved by establishing and maintaining effective safety.

The authority having jurisdiction is responsible for interpreting the specific rules of the *Code*. This paragraph empowers the authority having jurisdiction, using special permission (written consent), to permit alternative methods where specific rules are not established in the *Code*. For example, the authority having jurisdiction may waive specific requirements in industrial occupancies, research and testing laboratories, and other occupancies where the specific type of installation is not covered in the *Code*.

This *Code* may require new products, constructions, or materials that may not yet be available at the time the *Code*

is adopted. In such event, the authority having jurisdiction may permit the use of the products, constructions, or materials that comply with the most recent previous edition of this *Code* adopted by the jurisdiction.

The last paragraph of 90.4 permits the authority having jurisdiction to waive a new *Code* requirement during the interim period between acceptance of a new edition of the *NEC* and the availability of a new product, construction, or material redesigned to comply with the increased safety required by the latest edition. Establishing a viable future effective date in each section of the *NEC* is difficult because the time needed to change existing products and standards, as well as to develop new materials and test methods, usually is not known at the time the latest edition of the *Code* is adopted.

### 90.5 Mandatory Rules, Permissive Rules, and Explanatory Material

**(A) Mandatory Rules.** Mandatory rules of this *Code* are those that identify actions that are specifically required or prohibited and are characterized by the use of the terms *shall* or *shall not*.

The *Code* uses two distinctive types of rules: mandatory rules and permissive rules. Mandatory rules, characterized by the terms *shall* and *shall not*, are covered in 90.5(A).

**(B) Permissive Rules.** Permissive rules of this *Code* are those that identify actions that are allowed but not required, are normally used to describe options or alternative methods, and are characterized by the use of the terms *shall be permitted* or *shall not be required*.

Permissive rules are simply options or alternative methods of achieving equivalent safety — they are not requirements. A close reading of permissive terms is important because permissive rules are often misinterpreted. For example, the frequently used permissive term *shall be permitted* can be mistaken for a requirement. Substituting “the inspector must allow [item A or method A]” for “[item A or method A] shall be permitted” generally clarifies the interpretation.

**(C) Explanatory Material.** Explanatory material, such as references to other standards, references to related sections of this *Code*, or information related to a *Code* rule, is included in this *Code* in the form of **informational** notes. Such notes are informational only and are not enforceable as requirements of this *Code*.

Brackets containing section references to another NFPA document are for informational purposes only and are provided as a guide to indicate the source of the extracted text. These bracketed references immediately follow the extracted text.

A number of requirements in the *NEC* have been extracted from other NFPA codes and standards. Therefore, the second paragraph of 90.5(C) is intended to prevent any misunderstanding about the purpose of bracketed references to other NFPA codes and standards — they are provided only to indicate the section of the NFPA document from which the material in the *NEC* was extracted. Although *NEC* requirements based on extracted material are under the jurisdiction of the technical committee responsible for the particular document in which the extracted material resides, this revision to 90.5(C) makes it clear that the *NEC* requirements stand on their own and that extracted material with bracketed references does not indicate that other NFPA documents are adopted through reference.

The *NEC* contains a number of informational notes. Prior to the 2011 *Code*, these notes were referred to as *fine print notes* or *FPNs*. They have been renamed *informational notes* to clarify that they do not contain requirements, statements of intent, or recommendations. They present additional supplementary material that aids in the application of the requirement that they follow. In addition to the words “Informational Note” preceding the paragraph, the explanatory material is further identified by being in fine print (small type). Because informational notes are not requirements of the *NEC*, they are not enforceable.

Footnotes to tables, although also in fine print, are not explanatory material unless they are identified as informational notes. Table footnotes are part of the tables and are necessary for proper use of the tables. For example, the footnotes at the end of Tables 310.104(A) through (E) are necessary for the use of the table and therefore are mandatory and enforceable *Code* text.

Additional explanatory material is also found in the informative annexes at the back of this handbook. Prior to the 2011 *Code*, these annexes were referred to simply as annexes. The term *informative annex* clarifies that these annexes contain additional information. They do not contain recommendations or requirements. Informative Annex A is a reference list of product safety standards used for product listing where that listing is required by the *Code*. Informative Annex B provides guidance on the use of the general formula for ampacity found in 310.15(C). Informative Annex C consists of wire fill tables for conduit and tubing. Informative Annex D contains example calculations. Informative Annex E presents various tables showing fire resistance ratings for Type I to Type V construction to correlate with the uses of Type NM cable. Informative Annex F

provides information on reliability for critical operations power systems and on the development and implementation of functional performance tests for those systems. Informative Annex G contains information on supervisory control and data acquisition (SCADA) systems used in critical operations power systems. Finally, Informative Annex H contains a model law that can be used for administration and enforcement of this *Code* by a jurisdiction.

**Informational Note:** The format and language used in this *Code* follows guidelines established by NFPA and published in the *NEC Style Manual*. Copies of this manual can be obtained from NFPA.

This informational note informs the user that a style manual is available for the *NEC*. The *NEC Style Manual* contains a list of rules and regulations used by the panels and editors who prepare the *NEC*. The *NEC Style Manual*, which was revised for the 2002 edition of the *Code*, can be downloaded from the NFPA website.

**(D) Informative Annexes.** Nonmandatory information relative to the use of the *NEC* is provided in informative annexes. Informative annexes are not part of the enforceable requirements of the *NEC*, but are included for information purposes only.

## 90.6 Formal Interpretations

To promote uniformity of interpretation and application of the provisions of this *Code*, formal interpretation procedures have been established and are found in the NFPA Regulations Governing Committee Projects.

The procedures for Formal Interpretations of the provisions of the *NEC* are outlined in Section 6 of the NFPA Regulations Governing Committee Projects. These regulations are included in the *NFPA Codes and Standards Directory*, which is published annually and can be downloaded from the NFPA website.

The National Electrical Code Committee cannot be responsible for subsequent actions of authorities enforcing the *NEC* that accept or reject its findings. The authority having jurisdiction is responsible for interpreting *Code* rules and should attempt to resolve all disagreements at the local level. Two general forms of Formal Interpretations are recognized: (1) those that are interpretations of the literal text and (2) those that are interpretations of the intent of the Committee at the time the particular text was issued.

Interpretations of the *NEC* not subject to processing are those that involve (1) a determination of compliance of a design, installation, product, or equivalency of protection; (2) a

review of plans or specifications or judgment or knowledge that can be acquired only as a result of on-site inspection; (3) text that clearly and decisively provides the requested information; or (4) subjects not previously considered by the Technical Committee or not addressed in the document. Formal Interpretations of *Code* rules are published in several venues, including *necplus*®, *NFPA News*, the *National Fire Codes*® subscription service, and various trade publications. They are also found on the NFPA website.

Most interpretations of the *NEC* are rendered as the personal opinions of NFPA electrical engineering staff or of an involved member of the National Electrical Code Committee because the request for interpretation does not qualify for processing as a Formal Interpretation in accordance with NFPA Regulations Governing Committee Projects. Such opinions are rendered in writing only in response to written requests. The correspondence contains a disclaimer indicating that it is not a Formal Interpretation issued pursuant to NFPA Regulations and that any opinion expressed is the personal opinion of the author and does not necessarily represent the official position of NFPA or the National Electrical Code Committee.

## 90.7 Examination of Equipment for Safety

For specific items of equipment and materials referred to in this *Code*, examinations for safety made under standard conditions provide a basis for approval where the record is made generally available through promulgation by organizations properly equipped and qualified for experimental testing, inspections of the run of goods at factories, and service-value determination through field inspections. This avoids the necessity for repetition of examinations by different examiners, frequently with inadequate facilities for such work, and the confusion that would result from conflicting reports on the suitability of devices and materials examined for a given purpose.

It is the intent of this *Code* that factory-installed internal wiring or the construction of equipment need not be inspected at the time of installation of the equipment, except to detect alterations or damage, if the equipment has been listed by a qualified electrical testing laboratory that is recognized as having the facilities described in the preceding paragraph and that requires suitability for installation in accordance with this *Code*.

**Informational Note No. 1:** See requirements in 110.3.

**Informational Note No. 2:** *Listed* is defined in Article 100.

**Informational Note No. 3:** Informative Annex A contains an informative list of product safety standards for electrical equipment.

Testing laboratories, inspection agencies, and other organizations concerned with product evaluation publish lists of

equipment and materials that have been tested and meet nationally recognized standards or that have been found suitable for use in a specified manner. The *Code* does not contain detailed information on equipment or materials but refers to products as *listed*, *labeled*, or *identified*. See Article 100 for definitions of these terms. Many certification agencies also perform field evaluations of specific installations in order to render an opinion on compliance with the requirements of the *Code*, along with any applicable product standards.

NFPA does not approve, inspect, or certify any installations, procedures, equipment, or materials, nor does it approve or evaluate testing laboratories. In determining the acceptability of installations or procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, the authority may require evidence of proper installation, procedures, or use. The authority having jurisdiction may also refer to the listing or labeling practices of an organization concerned with product evaluations in order to determine compliance with appropriate standards for the current production of listed items.

Informative Annex A contains a list of product safety standards used for product listing. The list includes only product safety standards for which a listing is required by the *Code*. For example, 344.6 requires that rigid metal conduit, Type RMC, be listed. By using Informative Annex A, the user finds that the listing standard for rigid metal conduit is UL 6, *Rigid Metal Conduit*. Because associated conduit fittings are required to be listed, UL 514B, *Fittings for Cable and Conduit*, is found in Informative Annex A also.

## 90.8 Wiring Planning

**(A) Future Expansion and Convenience.** Plans and specifications that provide ample space in raceways, spare raceways, and additional spaces allow for future increases in electric power and communications circuits. Distribution centers located in readily accessible locations provide convenience and safety of operation.

The requirement for providing the exclusively dedicated equipment space mandated by 110.26(E) supports the intent of 90.8(A) regarding future increases in the use of electricity. It is important to consider communications circuits when planning future needs. Electrical and communications distribution centers should contain additional space and capacity for future additions and should be conveniently located for easy accessibility.

Where electrical and communications distribution equipment is installed so that easy access cannot be achieved, a spare raceway(s) or pull line(s) should be run at the initial installation, as illustrated in Exhibit 90.2. In com-

mercial and industrial facilities, it is common to purchase switchboards with additional capacity to accommodate future expansion. See Exhibit 90.3.

**(B) Number of Circuits in Enclosures.** It is elsewhere provided in this *Code* that the number of wires and circuits confined in a single enclosure be varyingly restricted. Limiting the number of circuits in a single enclosure minimizes the effects from a short circuit or ground fault in one circuit.

These limitations minimize the heating effects inherently present wherever current-carrying conductors are grouped together. See 408.36, Exception No. 2 for restrictions on the number of overcurrent devices on one panelboard.

## 90.9 Units of Measurement

**(A) Measurement System of Preference.** For the purpose of this *Code*, metric units of measurement are in accordance with the modernized metric system known as the International System of Units (SI).

According to a recent report titled “A Metric for Success” by the National Institute of Standards and Technology (NIST), most U.S. industries that do business abroad are predominantly metric already because of global sourcing of parts, service, components, and production. However, quite a few domestic industries still use U.S. customary units. The NIST report warns that domestic industries that ignore global realities and continue to design and manufacture with nonmetric measures will find that they risk increasing their costs. Nonmetric modular products (the building construction industry uses great quantities of modular parts) and those that interface with outside industry products are especially vulnerable to the added costs of adapting to a metric environment.

Metric standards are beginning to appear in the domestic building construction industry because our national standards are being harmonized with international standards.

**(B) Dual System of Units.** SI units shall appear first, and inch-pound units shall immediately follow in parentheses. Conversion from inch-pound units to SI units shall be based on hard conversion except as provided in 90.9(C).

**(C) Permitted Uses of Soft Conversion.** The cases given in 90.9(C)(1) through (C)(4) shall not be required to use hard conversion and shall be permitted to use soft conversion.

**(1) Trade Sizes.** Where the actual measured size of a product is not the same as the nominal size, trade size designators shall be used rather than dimensions. Trade practices shall be followed in all cases.

**EXHIBIT 90.2** A residential distribution system showing spare raceways or pull lines that allow for future circuits and loads for both electrical and communications systems.

Metric trade sizes (metric designators) of conduits appear in the *Code* text, preceding the trade size equivalents, in the raceway articles.

For example, in 350.20(A) of this *Code*, the size requirement is stated as follows: “LFMC smaller than metric designator 16 (trade size ½) shall not be used.”

This convention provides acceptable language to both domestic and international users of the *NEC*. For ease of use, in Table 4 of Chapter 9, metric designators and trade sizes are in separate columns.

**(2) Extracted Material.** Where material is extracted from another standard, the context of the original material shall not be compromised or violated. Any editing of the extracted text shall be confined to making the style consistent with that of the *NEC*.

**(3) Industry Practice.** Where industry practice is to express units in inch-pound units, the inclusion of SI units shall not be required.

The following calculation examples illustrate conversions from U.S. customary units (sometimes referred to as inch-pound units) to SI units. Example 1 shows the process of

converting a dimension from feet to meters, where safety is a concern. Table 110.31 contains minimum permitted distances from a fence to a live part for voltages 601 and greater.

#### Calculation Example 1

Determine the equivalent metric conversion for 10 ft where the calculation could have a negative impact on safety, such as the minimum distance of 10 ft given in Table 110.31, and where the measurement is from a fence to a live part from 601 volts to 13,799 volts.

#### Solution

STEP 1. Use the following equation to determine the equivalent metric conversion for 10 ft:

$$10 \text{ ft} \times \frac{0.3048 \text{ m}}{1 \text{ ft}} = 3.048 \text{ m}$$

STEP 2. Round up the calculation to 3.05 m because a distance less than 3.048 could have a negative impact on safety. The answer, 3.05 m, matches the minimum distance in Table 110.31 from a fence to a live part from 601 volts to 13,799 volts.

Because safety is a concern for this conversion calculation, the original *Code* distance (the U.S. customary units for this example) remains the shortest permitted distance.

**EXHIBIT 90.3** A switchboard with spare circuit breakers installed to facilitate future growth. (Courtesy of the International Association of Electrical Inspectors)

The final metric equivalent ends up slightly larger. The exact difference is of no practical concern, however, because 0.2 mm is less than  $\frac{1}{32}$  in. From a practical point of view, a variance of  $\frac{1}{32}$  in. in a length of 10 ft is insignificant.

#### Calculation Example 2

Using the soft-conversion method, determine the equivalent metric conversion for 30 in. where the calculation could have a negative impact on safety, such as a 30-in. minimum horizontal working space requirement in the rear of equipment that requires access to nonelectrical parts according to 110.26(A)(1)(a).

#### Solution

**STEP 1.** Use the following equation to determine the equivalent metric conversion for 30 in.:

$$30 \text{ in.} \times \frac{25.4 \text{ mm}}{1 \text{ in.}} = 762 \text{ mm}$$

**STEP 2.** Do not round off the calculation, because even a slight reduction in the original distance could have a negative impact on safety. The answer is 762 mm, which matches the minimum distance of 110.26(A)(1)(a) for a minimum horizontal working space.

**(4) Safety.** Where a negative impact on safety would result, soft conversion shall be used.

Hard conversion is explained in the informational note No. 1 following 90.9(D). Calculations to convert measurements from inch-pound units to metric units must be made using hard conversion. The hard-conversion method is mandatory except for trade sizes [e.g., raceway sizes in Table 300.1(C)], extracted material (e.g., class and zone measurements from other NFPA documents), and safety calculations (e.g., minimum distances taken from Table 110.31).

#### Calculation Example

Using the hard-conversion method, determine the equivalent metric conversion for 24 in., generally the minimum cover requirements for direct burial cables and conductors in non-specific locations taken from row 1 of Table 300.5.

#### Solution

**STEP 1.** Use the following equation to determine the equivalent metric conversion for 24 in.:

$$24 \text{ in.} \times \frac{25.4 \text{ mm}}{1 \text{ in.}} = 609.6 \text{ mm}$$

**STEP 2.** Because the calculation is being performed as a hard conversion, the 609.6 mm dimension may be changed, and the selected equivalent cover requirement is 600 mm.

The measurements of 600 mm and 24 in. appear in Table 300.5 for the minimum cover requirements for direct burial cables and conductors in nonspecific locations. For the 1999 *NEC*, the selected SI unit of measure was required to be 609.6 mm. The 2005 *Code* (as well as the 2002 *Code*) permitted much more latitude for the final selected dimension, and so the equivalent minimum cover requirement of 600 mm is a more practical solution. Basically, a hard conversion permits a change in a dimension or allows rounding up or down to better fit the physical constraints of the installation.

**(D) Compliance.** Conversion from inch-pound units to SI units shall be permitted to be an approximate conversion. Compliance with the numbers shown in either the SI system

or the inch-pound system shall constitute compliance with this *Code*.

Informational Note No. 1: Hard conversion is considered a change in dimensions or properties of an item into new sizes that might or might not be interchangeable with the sizes used in the original measurement. Soft conversion is considered a direct mathematical conversion and involves a change in the description of an existing measurement but not in the actual dimension.

Informational Note No. 2: SI conversions are based on IEEE/ASTM SI 10-1997, *Standard for the Use of the International System of Units (SI): The Modern Metric System*.

Commentary Table 90.1 offers some examples of the hard-conversion process. The equivalent U.S. units are given only to show the small variance between customary units and the hard-conversion units.

Warning signs that state specific clearances, such as required in 513.10(B), permit distance measurements in either inch-pound units or metric units.

**COMMENTARY TABLE 90.1** Conversions Using the Hard-Conversion Method

U.S. Customary Units	Soft Conversions, SI Units	Hard Conversions, SI Units	Equivalent U.S. Customary Units
$\frac{1}{2}$ in.	12.7 mm	13 mm	0.51 in.
$\frac{3}{4}$ in.	19 mm	19 mm	0.75 in.
1 in.	25.4 mm	25 mm	0.98 in.
4 in.	102 mm	100 mm	3.94 in.
12 in.	305 mm	300 mm	11.81 in.
2 ft	610 mm	600 mm	1.97 ft
3 ft	914 mm	900 mm	2.95 ft
6 ft	1.83 m	1.8 m	5.91 ft
15 ft	4.57 m	4.5 m	14.76 ft

## ARTICLE 100 Definitions

### Contents

- I. General
- II. Over 600 Volts, Nominal

**Scope.** This article contains only those definitions essential to the proper application of this *Code*. It is not intended to include commonly defined general terms or commonly defined technical terms from related codes and standards. In general, only those terms that are used in two or more articles are defined in Article 100. Other definitions are included in the article in which they are used but may be referenced in Article 100.

Part I of this article contains definitions intended to apply wherever the terms are used throughout this *Code*. Part II contains definitions applicable only to the parts of

articles specifically covering installations and equipment operating at over 600 volts, nominal.

Commonly defined general terms include those terms defined in general English language dictionaries and terms that are not used in a unique or restricted manner in the *NEC*. Commonly defined technical terms such as *volt* (abbreviated V) and *ampere* (abbreviated A) are found in the *IEEE Standard Dictionary of Electrical and Electronic Terms*.

Some definitions that are not listed in Article 100 are included in their appropriate article. For articles that follow the common format according to the *NEC Style Manual*, the section number is generally XXX.2 Definition(s). For example, the definition of *nonmetallic-sheathed cable* is found in 334.2 Definitions.

Many of the definitions in Article 100 are now assigned to code-making panels other than Panel 1. The assignments are as shown in Commentary Table 100.1.

## I. General

**Accessible (as applied to equipment).** Admitting close approach; not guarded by locked doors, elevation, or other effective means.

Exhibit 100.1 illustrates examples of equipment considered accessible (as applied to equipment) in accordance with requirements elsewhere in the *Code*. The main rule for switches and circuit breakers used as switches is shown in

(a) and is according to 404.8(A). In (b), the busway installation is according to 368.17(C). The exceptions to 404.8(A) are illustrated in (c), busway switches installed according to Exception No. 1; in (d), a switch installed adjacent to a motor according to Exception No. 2; and in (e), a hookstick-operated isolating switch installed according to Exception No. 3.

**Accessible (as applied to wiring methods).** Capable of being removed or exposed without damaging the building

**EXHIBIT 100.1** Example of a busway and of switches considered accessible even if located above the 6 ft 7 in. maximum height of the switch handle, which is specified in 404.8(A).

structure or finish or not permanently closed in by the structure or finish of the building.

Wiring methods located behind removable panels designed to allow access are not considered permanently enclosed and are considered exposed as applied to wiring methods. See 300.4(C) regarding cables located in spaces behind accessible panels. Exhibit 100.2 illustrates an example of wiring methods and equipment that are considered accessible despite being located above a suspended ceiling.

**Accessible, Readily (Readily Accessible).** Capable of being reached quickly for operation, renewal, or inspections without requiring those to whom ready access is requisite to climb over or remove obstacles or to resort to portable ladders, and so forth.

The definition of *readily accessible* does not preclude the use of a locked door for service equipment or rooms containing service equipment, provided those for whom ready access is necessary have a key (or lock combination) available. Sections 230.70(A)(1) and 230.205(A) require service-disconnecting means to be readily accessible. However, 230.205(A) permits overhead or underground primary distribution systems on services of over 600 volts, nominal on

**EXHIBIT 100.2** Example of an accessible busway and junction box located above hung ceilings having lift-out panels.

private property to have a disconnecting means that is not readily accessible provided that there is a readily accessible means to operate the disconnecting means through a mechanical linkage or through an electronically actuated means.

Section 225.32 requires that feeder disconnecting means for separate buildings be readily accessible. A commonly used, permitted practice is to locate the disconnecting means in the electrical equipment room of an office building or large apartment building and to keep the door to that room locked to prevent access by unauthorized persons. Section 240.24(A) requires that overcurrent devices be so located as to be readily accessible. Exhibit 100.3 shows an example of a locked electrical equipment door with a warning sign that restricts access.

**Ampacity.** The **maximum** current, in amperes, that a conductor can carry continuously under the conditions of use without exceeding its temperature rating.

The definition of the term *ampacity* states that the maximum current a conductor carries continuously varies with the conditions of use as well as with the temperature rating of the conductor insulation. For example, ambient temperature is a condition of use. A conductor with insulation rated at 60°C and installed near a furnace where the ambient temperature is continuously maintained at 60°C has no current-carrying capacity. Any current flowing through the conductor will raise its temperature above the 60°C insulation rating. Therefore, the ampacity of this conductor, regardless of its size, is zero. See the ampacity correction factors for temperature in Tables 310.15(B)(2)(a) and 310.15(B)(2)(b) or

**EXHIBIT 100.3** Warning on locked electrical equipment door.

see Informative Annex B. The temperature limitation on conductors is further explained, and examples are given in 310.15(B)(2) and in the commentary following that section. Another condition of use is the number of conductors in a raceway or cable. [See 310.15(B)(3)(a).]

**Appliance.** Utilization equipment, generally other than industrial, that is normally built in standardized sizes or types and is installed or connected as a unit to perform one or more functions such as clothes washing, air conditioning, food mixing, deep frying, and so forth.

**Approved.** Acceptable to the authority having jurisdiction.

See the definition of *authority having jurisdiction* and 110.2 for a better understanding of the approval process. Typically, approval of listed equipment will more readily be given by an authority having jurisdiction where the authority accepts the laboratory's listing mark. Other options may be available for the jurisdiction to approve equipment, including evaluation by the inspection authority or field evaluation by a qualified laboratory or individual. Where an evaluation is conducted on site, industry standards such as NFPA 79, *Electrical Standard for Industrial Machinery* (if applicable), can be used.

**Arc-Fault Circuit Interrupter (AFCI).** A device intended to provide protection from the effects of arc faults by recognizing characteristics unique to arcing and by functioning to de-energize the circuit when an arc fault is detected.

The basic objective of an arc-fault circuit interrupter is to de-energize the branch circuit when an arc fault is detected. Arc-fault circuit interrupters are evaluated in UL 1699, *Standard for Arc-Fault Circuit-Interrupters*, using testing methods that create or simulate arcing conditions to determine a product's ability to detect and interrupt arcing faults. These devices are also tested to verify that arc detection is not unduly inhibited by the presence of loads and circuit characteristics that may mask the hazardous arcing condition. In addition, these devices are evaluated to determine resistance to unwanted tripping due to the presence of arcing that occurs in control and utilization equipment under normal operating conditions or to a loading condition that closely mimics an arcing fault, such as a solid-state electronic ballast or a dimmed load.

**Askarel.** A generic term for a group of nonflammable synthetic chlorinated hydrocarbons used as electrical insulating media. Askarels of various compositional types are used. Under arcing conditions, the gases produced, while consisting predominantly of noncombustible hydrogen chloride, can include varying amounts of combustible gases, depending on the askarel type.

**Attachment Plug (Plug Cap) (Plug).** A device that, by insertion in a receptacle, establishes a connection between the conductors of the attached flexible cord and the conductors connected permanently to the receptacle.

Standard attachment caps are available with built-in options, such as switching, fuses, or even ground-fault circuit interrupter (GFCI) protection. Attachment plug contact blades have specific shapes, sizes, and configurations so that a receptacle or cord connector will not accept an attachment plug of a voltage or current rating different from that for which the device is intended. See 406.7 for requirements pertaining to attachment plugs and the configuration charts from NEMA WD 6, *Wiring Devices — Dimensional Requirements*, for general-purpose nonlocking and specific-purpose locking plugs and receptacles shown in Exhibit 406.3.

**Authority Having Jurisdiction (AHJ).** An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

**Informational Note:** The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building

official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

The important role of the authority having jurisdiction (AHJ) cannot be overstated in the current North American safety system. The basic role of the AHJ is to verify that an installation complies with the *Code*. See also the definition of *approved*, 90.7, and 110.2.

**Automatic.** Performing a function without the necessity of human intervention.

**Bathroom.** An area including a basin with one or more of the following: a toilet, a urinal, a tub, a shower, a bidet, or similar plumbing fixtures.

**Bonded (Bonding).** Connected to establish electrical continuity and conductivity.

Bonding, which establishes an effective path for fault current that, in turn, facilitates the operation of the overcurrent protective device, is treated in the requirements of 250.4(A)(3) and (4) and 250.4(B)(3) and (4). Specific bonding requirements are found in Part V of Article 250 and in other sections of the *Code* as referenced in 250.3.

**Bonding Conductor or Jumper.** A reliable conductor to ensure the required electrical conductivity between metal parts required to be electrically connected.

The term *bonding jumper* was revised to *bonding conductor or jumper* for the 2011 *Code*. Either of the two terms *bonding conductor* or *bonding jumper* may be used. The term *bonding jumper* may be interpreted to imply a short conductor. However, some bonding jumpers may be several feet in length. The primary purpose of a bonding conductor or jumper is to ensure electrical conductivity between two conductive bodies, such as between a box and a metal raceway. Bonding jumpers are particularly important where a box has either concentric- or eccentric-type knockouts. These knockouts can impair the electrical conductivity between metal parts and may actually introduce unnecessary impedance into the grounding path. Bonding jumpers may be found at service equipment [250.92(B)], equipment operating over 250 volts (250.97), and expansion fittings in metal raceways

(250.98). Exhibit 100.4 shows the difference between concentric- and eccentric-type knockouts. Exhibit 100.4 also illustrates one method of applying bonding jumpers at these types of knockouts.

**EXHIBIT 100.4** Bonding jumpers installed around concentric or eccentric knockouts.

**Bonding Jumper, Equipment.** The connection between two or more portions of the equipment grounding conductor.

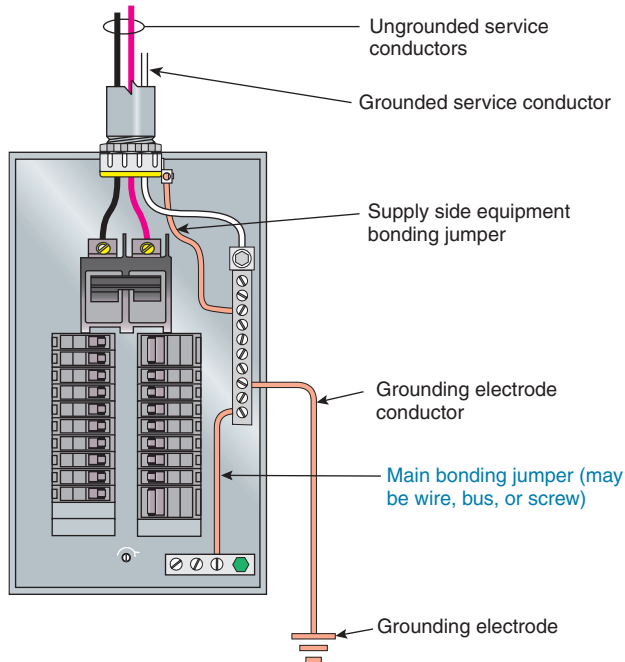

The main purpose of equipment bonding jumpers is to ensure that the electrical continuity of an effective ground-fault current path is not compromised by an interruption in mechanical or electrical continuity. For example, conduits entering an open-bottom switchboard are usually not mechanically connected to the switchboard. Bonding jumpers provide electrical continuity. An example of potential loss of both mechanical and electrical continuity would be an installation of an expansion fitting intended to allow for movement in a metal conduit system, as illustrated in Exhibit 100.5. Expansion fittings consist of loosely joined raceways that allow expansion without deformation of the raceway. Some expansion fittings for metal conduit have an internal bonding jumper that is integral to the fitting, eliminating the need for the external bonding jumpers shown in Exhibit 100.5. Equipment bonding jumpers are also used to connect the grounding terminal of a receptacle to a metal box that in turn is grounded via an equipment grounding conductor (the raceway system).

**Bonding Jumper, Main.** The connection between the grounded circuit conductor and the equipment grounding conductor at the service.

Exhibit 100.6 shows a main bonding jumper that provides the connection between the grounded service conductor and

**EXHIBIT 100.5** Equipment bonding jumpers installed to maintain electrical continuity around conduit expansion fittings. (Courtesy of the International Association of Electrical Inspectors)

**EXHIBIT 100.6** A main bonding jumper installed at the service between the grounded service conductor and the equipment grounding conductor.

the equipment grounding conductor at the service. Bonding jumpers may be located throughout the electrical system, but a main bonding jumper is located only at the service. Main bonding jumper requirements are found in 250.28.

**Bonding Jumper, System.** The connection between the grounded circuit conductor and the supply-side bonding jumper, or the equipment grounding conductor, or both, at a separately derived system.

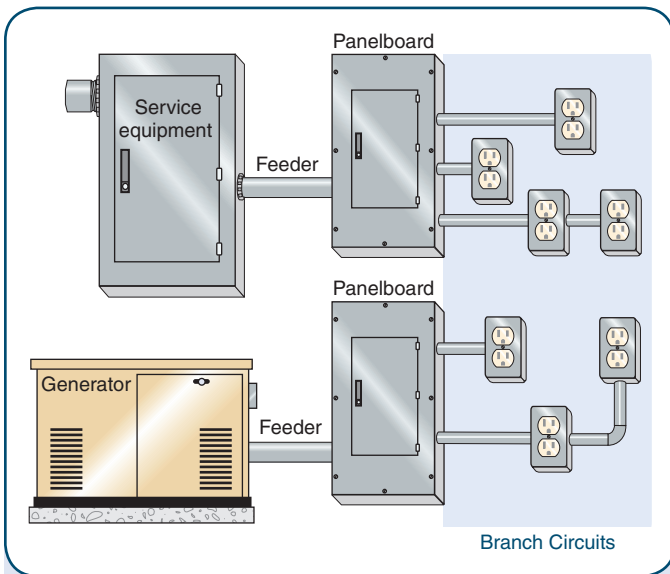

This definition was revised for the 2011 *Code* to clarify the function of the system bonding jumper. The system bonding jumper can be installed in several ways. For example, if a multi-barrel lug is connected to the XO terminal of a transformer, the system bonding jumper, grounding electrode conductor, grounded conductor, and bonding jumper can be connected at that connector. If a multi-barrel lug is connected to the transformer or generator enclosure, it is common to connect the system bonding jumper, grounding electrode conductor and the bonding jumper or conductor to that connector. The grounded conductor should always connect directly to the XO terminal. A system bonding jumper is used to connect the equipment grounding conductor(s) or the supply side bonding jumper to the grounded conductor of a separately derived system either at the source (see Exhibit 250.13) or at the first system disconnecting means (see Exhibit 250.14). A system bonding jumper is used at the derived system if the derived system contains a grounded conductor. Like the main bonding jumper at the service equipment, the system bonding jumper provides the necessary link between the equipment grounding conductors and the system grounded conductor in order to establish an effective path for ground-fault current to return to the source. The requirements for system bonding jumper(s) are found in 250.30(A)(1).

**Branch Circuit.** The circuit conductors between the final overcurrent device protecting the circuit and the outlet(s).

Exhibit 100.7 shows the difference between branch circuits and feeders. Conductors between the overcurrent devices in the panelboards and the duplex receptacles are branch-circuit conductors. Conductors between the service equipment or source of separately derived systems and the panelboards are feeders.

**Branch Circuit, Appliance.** A branch circuit that supplies energy to one or more outlets to which appliances are to be connected and that has no permanently connected luminaires that are not a part of an appliance.

Two or more 20-ampere small-appliance branch circuits are required by 210.11(C)(1) for dwelling units. Section 210.52(B)(1) requires that these circuits supply receptacle outlets located in such rooms as the kitchen, pantry, and so

**EXHIBIT 100.7** Feeder (circuits) and branch circuits.

on. These small-appliance branch circuits are not permitted to supply other outlets or permanently connected luminaires. (See 210.52 for exact details.)

**Branch Circuit, General-Purpose.** A branch circuit that supplies two or more receptacles or outlets for lighting and appliances.

**Branch Circuit, Individual.** A branch circuit that supplies only one utilization equipment.

Exhibit 100.8 illustrates an individual branch circuit with a single receptacle for connection of one piece of utilization

**EXHIBIT 100.8** An individual branch circuit, supplying only one piece of utilization equipment via a single receptacle.

equipment (e.g., one dryer, one range, one space heater, one motor). See 210.23 regarding permissible loads for individual branch circuits, as well as 210.21(B)(1), which requires the single receptacle to have an ampere rating not less than that of the branch circuit. A branch circuit supplying one duplex receptacle that supplies two cord-and-plug-connected appliances or similar equipment is not an individual branch circuit.

**Branch Circuit, Multiwire.** A branch circuit that consists of two or more ungrounded conductors that have a voltage between them, and a grounded conductor that has equal voltage between it and each ungrounded conductor of the circuit and that is connected to the neutral or grounded conductor of the system.

See 210.4, 240.15(B)(1), and 300.13(B) for specific information about multiwire branch circuits.

**Building.** A structure that stands alone or that is cut off from adjoining structures by fire walls with all openings therein protected by approved fire doors.

A building is generally considered to be a roofed or walled structure that may be used or intended for supporting or sheltering any use or occupancy. However, it may also be a separate structure such as a pole, billboard sign, or water tower. Definitions of the terms *fire walls* and *fire doors* are the responsibility of building codes. Generically, a fire wall may be defined as a wall that separates buildings or subdivides a building to prevent the spread of fire and that has a fire resistance rating and structural stability. Fire doors (and fire windows) are used to protect openings in walls, floors, and ceilings against the spread of fire and smoke within, into, or out of buildings.

**Cabinet.** An enclosure that is designed for either surface mounting or flush mounting and is provided with a frame, mat, or trim in which a swinging door or doors are or can be hung.

Both cabinets and cutout boxes are covered in Article 312. Cabinets are designed for surface or flush mounting with a trim to which a swinging door(s) is hung. Cutout boxes are designed for surface mounting with a swinging door(s) secured directly to the box. Panelboards are electrical assemblies designed to be placed in a cabinet or cutout box. (See the definitions of *cutout box* and *panelboard*.)

**Circuit Breaker.** A device designed to open and close a circuit by nonautomatic means and to open the circuit automatically on a predetermined overcurrent without damage to itself when properly applied within its rating.

*Informational Note:* The automatic opening means can be integral, direct acting with the circuit breaker, or remote from the circuit breaker.

*Adjustable (as applied to circuit breakers).* A qualifying term indicating that the circuit breaker can be set to trip at various values of current, time, or both, within a predetermined range.

*Instantaneous Trip (as applied to circuit breakers).* A qualifying term indicating that no delay is purposely introduced in the tripping action of the circuit breaker.

*Inverse Time (as applied to circuit breakers).* A qualifying term indicating that there is purposely introduced a delay in the tripping action of the circuit breaker, which delay decreases as the magnitude of the current increases.

*Nonadjustable (as applied to circuit breakers).* A qualifying term indicating that the circuit breaker does not have any adjustment to alter the value of current at which it will trip or the time required for its operation.

*Setting (of circuit breakers).* The value of current, time, or both, at which an adjustable circuit breaker is set to trip.

**Clothes Closet.** A non-habitable room or space intended primarily for storage of garments and apparel.

This definition helps to determine whether the rules of 240.24(D), 410.8, and 550.11(A) apply to an installation. If the definition does not apply, the area may be classified as something other than a clothes closet, such as a bedroom. Other requirements may then be applied, such as 210.52 and 210.70.

**Communications Equipment.** The electronic equipment that performs the telecommunications operations for the transmission of audio, video, and data, and includes power equipment (e.g., dc converters, inverters, and batteries) and technical support equipment (e.g., computers).

This definition clearly indicates that power supplies and computers are considered part of the communications equipment and are thus subject to requirements that apply to that equipment. The telephone switch shown in Exhibit 100.9, for example, is considered part of telecommunications equipment and so is subject to the same requirements. The definition correlates with NFPA 76, *Standard for the Fire Protection of Telecommunications Facilities*.

**EXHIBIT 100.9** A private automatic branch exchange, one part of telecommunications equipment.

**Concealed.** Rendered inaccessible by the structure or finish of the building. Wires in concealed raceways are considered concealed, even though they may become accessible by withdrawing them.

Raceways and cables supported or located within hollow frames or permanently closed in by the finish of buildings are considered concealed. Open-type work — such as raceways and cables in unfinished basements, in accessible underfloor areas or attics, or behind, above, or below panels designed to allow access and that may be removed without damage to the building structure or finish — is not considered concealed. [See definition of *exposed (as applied to wiring methods)*.]

**Conductor, Bare.** A conductor having no covering or electrical insulation whatsoever.

**Conductor, Covered.** A conductor encased within material of composition or thickness that is not recognized by this Code as electrical insulation.

Typical covered conductors are the green-covered equipment grounding conductors contained within a nonmetallic-sheathed cable or the uninsulated grounded system conductors within the overall exterior jacket of a Type SE cable. Covered conductors should always be treated as bare conductors for working clearances because they are really uninsulated conductors. See the definition of *insulated conductor* that follows and the requirements in Article 310.

**Conductor, Insulated.** A conductor encased within material of composition and thickness that is recognized by this *Code* as electrical insulation.

For the covering on a conductor to be considered insulation by this *Code*, conductors with covering material are generally required to pass minimum testing required by a product standard. One such product standard is UL 83, *Thermoplastic-Insulated Wires and Cables*. To meet the requirements of UL 83, specimens of finished single-conductor wires must pass specified tests that measure (1) resistance to flame propagation, (2) dielectric strength, even while immersed, and (3) resistance to abrasion, cracking, crushing, and impact. Only wires and cables that meet the minimum fire, electrical, and physical properties required by the applicable product standards are permitted to be marked with the letter designations found in Table 310.104(A). See 310.104 for the exact requirements of insulated conductor construction and applications.

**Conduit Body.** A separate portion of a conduit or tubing system that provides access through a removable cover(s) to

the interior of the system at a junction of two or more sections of the system or at a terminal point of the system.

Boxes such as FS and FD or larger cast or sheet metal boxes are not classified as conduit bodies.

Conduit bodies include the short-radius type as well as capped elbows and service-entrance elbows. Some conduit bodies are referred to in the trade as “condulets” and include the LB, LL, LR, C, T, and X designs. A typical conduit body is shown in Exhibit 100.10. See 300.15 and Article 314 for rules on the usage of conduit bodies. Type FS and Type FD boxes, which are not classified as conduit bodies, are listed with boxes in Table 314.16(A).

**Connector, Pressure (Solderless).** A device that establishes a connection between two or more conductors or between one or more conductors and a terminal by means of mechanical pressure and without the use of solder.

**Continuous Load.** A load where the maximum current is expected to continue for 3 hours or more.

**Controller.** A device or group of devices that serves to govern, in some predetermined manner, the electric power delivered to the apparatus to which it is connected.

A controller may be a remote-controlled magnetic contactor, switch, circuit breaker, or other device that is normally used to start and stop motors and other apparatus and, in the case of motors, is required by 110.9 and 430.82 to be capable of interrupting the stalled-rotor current of the motor. Stop-and-start stations and similar control circuit components that do

**EXHIBIT 100.10** Typical conduit bodies. (Courtesy of the National Electrical Contractors Association)

not open the power conductors to the motor are not considered controllers.

**Cooking Unit, Counter-Mounted.** A cooking appliance designed for mounting in or on a counter and consisting of one or more heating elements, internal wiring, and built-in or mountable controls.

**Coordination (Selective).** Localization of an overcurrent condition to restrict outages to the circuit or equipment affected, accomplished by the choice of overcurrent protective devices and their ratings or settings.

Overcurrent protective devices, such as fuses and circuit breakers, have time/current characteristics that determine the time it takes to clear the fault for a given value of fault current. Selectivity occurs when the device closest to the fault opens before the next device upstream operates. For example, any fault on a branch circuit should open the branch-circuit breaker rather than the feeder overcurrent protection. All faults on a feeder should open the feeder overcurrent protection rather than the service overcurrent protection. When selectivity occurs, the electrical system is considered to be coordinated.

With coordinated overcurrent protection, the faulted or overloaded circuit is isolated by the selective operation of only the overcurrent protective device closest to the overcurrent condition. The main goal of selective coordination is to isolate the faulted portion of the electrical circuit quickly while at the same time maintaining power to the remainder of the electrical system. The electrical system overcurrent protection must guard against short circuits and ground faults to ensure that the resulting damage is minimized while other parts of the system not directly involved with the fault are kept operational until other protective devices clear the fault.

Selective coordination requirements include emergency systems, legally required standby systems, and critical operations power systems of 700.27, 701.27, and 708.54, respectively. The past *Code* requirements regarding selective coordination for elevator feeders remain in 620.62.

**Copper-Clad Aluminum Conductors.** Conductors drawn from a copper-clad aluminum rod with the copper metallurgically bonded to an aluminum core. The copper forms a minimum of 10 percent of the cross-sectional area of a solid conductor or each strand of a stranded conductor.

**Cutout Box.** An enclosure designed for surface mounting that has swinging doors or covers secured directly to and telescoping with the walls of the box proper.

**Dead Front.** Without live parts exposed to a person on the operating side of the equipment.

**Demand Factor.** The ratio of the maximum demand of a system, or part of a system, to the total connected load of a system or the part of the system under consideration.

**Device.** A unit of an electrical system that carries or controls electric energy as its principal function.

Components (such as switches, circuit breakers, fuseholders, receptacles, attachment plugs, and lampholders) that distribute or control but do not consume electrical energy are considered devices. Devices that consume incidental amounts of electrical energy in the performance of carrying or controlling electricity are also considered devices. Some examples of these components include a switch with an internal pilot light, a GFCI receptacle, and even a magnetic contactor.

**Disconnecting Means.** A device, or group of devices, or other means by which the conductors of a circuit can be disconnected from their source of supply.

For disconnecting means for service equipment, see Part VI of Article 230; for fuses, see Part IV of Article 240; for circuit breakers, see Part VII of Article 240; for appliances, see Part III of Article 422; for space-heating equipment, see Part III of Article 424; for motors and controllers, see Part IX of Article 430; and for air-conditioning and refrigerating equipment, see Part II of Article 440. (See also references for *disconnecting means* in the index.)

**Dusttight.** Constructed so that dust will not enter the enclosing case under specified test conditions.

Requirements for enclosures are found in 110.28, and Table 110.28, Enclosure Selection, provides a basis for selecting enclosure types that are dusttight. (See also the commentary following the definition of *enclosure*.)

**Duty, Continuous.** Operation at a substantially constant load for an indefinitely long time.

**Duty, Intermittent.** Operation for alternate intervals of (1) load and no load; or (2) load and rest; or (3) load, no load, and rest.

**Duty, Periodic.** Intermittent operation in which the load conditions are regularly recurrent.

**Duty, Short-Time.** Operation at a substantially constant load for a short and definite, specified time.

**Duty, Varying.** Operation at loads, and for intervals of time, both of which may be subject to wide variation.

Information on the protection of intermittent, periodic, short-time, and varying-duty motors against overload can be found in 430.33.

**Dwelling, One-Family.** A building that consists solely of one dwelling unit.

**Dwelling, Two-Family.** A building that consists solely of two dwelling units.

**Dwelling, Multifamily.** A building that contains three or more dwelling units.

**Dwelling Unit.** A single unit, providing complete and independent living facilities for one or more persons, including permanent provisions for living, sleeping, cooking, and sanitation.

Where dwelling units are referenced throughout the *Code*, it is important to note that rooms in motels, hotels, and similar occupancies could be classified as dwelling units if they satisfy the requirements of the definition. Exhibit 100.11 illustrates a motel or hotel room that clearly meets the definition because it has permanent provisions for living, sleeping, cooking, and sanitation. See also the definition of *mobile home* in 550.2.

**EXHIBIT 100.11** Example of motel or hotel room considered to be a dwelling unit.

**Electric Sign.** A fixed, stationary, or portable self-contained, electrically illuminated utilization equipment with words or symbols designed to convey information or attract attention.

**Electric Power Production and Distribution Network.** Power production, distribution, and utilization equipment and facilities, such as electric utility systems that deliver electric power to the connected loads, that are external to and not controlled by an interactive system.

**Enclosed.** Surrounded by a case, housing, fence, or wall(s) that prevents persons from accidentally contacting energized parts.

**Enclosure.** The case or housing of apparatus, or the fence or walls surrounding an installation to prevent personnel from accidentally contacting energized parts or to protect the equipment from physical damage.

Informational Note: See Table 110.28 for examples of enclosure types.

Enclosures are required by 110.28 to be marked with a number that identifies the locations where the type can be used. Enclosures that comply with the requirements for more than one type of enclosure are marked with multiple designations. See the commentary following 110.28 for details on enclosure markings and types and also see Table 110.28, which lists the types of enclosures required to be used in specific locations.

**Energized.** Electrically connected to, or is, a source of voltage.

The term *energized* is not limited to equipment that is “connected to a source of voltage.” Equipment such as batteries, capacitors, and conductors with induced voltages must also be considered energized. Also see the definitions of *exposed (as applied to live parts)* and *live parts*.

**Equipment.** A general term, including fittings, devices, appliances, luminaires, apparatus, machinery, and the like used as a part of, or in connection with, an electrical installation.

This definition was revised to clarify that machinery is also considered equipment. For further information on machinery, see Article 670 and NFPA 79, *Electrical Standard for Industrial Machinery*.

**Explosionproof Equipment.** Equipment enclosed in a case that is capable of withstanding an explosion of a specified gas or vapor that may occur within it and of preventing the ignition of a specified gas or vapor surrounding the enclosure by sparks, flashes, or explosion of the gas or vapor within, and that operates at such an external temperature that a surrounding flammable atmosphere will not be ignited thereby.

Informational Note: For further information, see ANSI/UL 1203-2006, *Explosion-Proof and Dust-Ignition-Proof Electrical Equipment for Use in Hazardous (Classified) Locations*.

**Exposed (as applied to live parts).** Capable of being inadvertently touched or approached nearer than a safe distance by a person. It is applied to parts that are not suitably guarded, isolated, or insulated.

This definition applies to energized live parts that must be guarded to avoid accidental contact and injury. See 110.27 for the requirements for guarding live parts. Also see the definitions of *energized* and *live parts*.

**Exposed (as applied to wiring methods).** On or attached to the surface or behind panels designed to allow access.

See Exhibit 100.2, which illustrates wiring methods that would be considered “exposed” because they are located above a suspended ceiling with lift-out panels.

**Externally Operable.** Capable of being operated without exposing the operator to contact with live parts.

**Feeder.** All circuit conductors between the service equipment, the source of a separately derived system, or other power supply source and the final branch-circuit overcurrent device.

See the commentary following the definition of *branch circuit*, including Exhibit 100.7, which illustrates the difference between branch circuits and feeders.

**Festoon Lighting.** A string of outdoor lights that is suspended between two points.

The general requirements for festoon lighting are located in 225.6(B).

**Fitting.** An accessory such as a locknut, bushing, or other part of a wiring system that is intended primarily to perform a mechanical rather than an electrical function.

Items such as condulets, conduit couplings, EMT connectors and couplings, and threadless connectors are considered fittings.

**Garage.** A building or portion of a building in which one or more self-propelled vehicles can be kept for use, sale, storage, rental, repair, exhibition, or demonstration purposes.

Informational Note: For commercial garages, repair and storage, see Article 511.

The definition of *garage* includes the garages for electric vehicles, covered in Article 625.

**Ground.** The earth.

**Ground Fault.** An unintentional, electrically conducting connection between an ungrounded conductor of an electrical circuit and the normally non-current-carrying conductors, metallic enclosures, metallic raceways, metallic equipment, or earth.

**Grounded (Grounding).** Connected (connecting) to ground or to a conductive body that extends the ground connection.

**Grounded, Solidly.** Connected to ground without inserting any resistor or impedance device.

**Grounded Conductor.** A system or circuit conductor that is intentionally grounded.

**Ground-Fault Circuit Interrupter (GFCI).** A device intended for the protection of personnel that functions to de-energize a circuit or portion thereof within an established period of time when a current to ground exceeds the values established for a Class A device.

Informational Note: Class A ground-fault circuit interrupters trip when the current to ground is 6 mA or higher and do not trip when the current to ground is less than 4 mA. For further information, see UL 943, *Standard for Ground-Fault Circuit Interrupters*.

The commentary following 210.8 contains a list of applicable cross-references for ground-fault circuit interrupters (GFCIs). Exhibits 210.6 through 210.16 contain specific information regarding the requirements for GFCIs.

**Ground-Fault Protection of Equipment.** A system intended to provide protection of equipment from damaging line-to-ground fault currents by operating to cause a disconnecting means to open all ungrounded conductors of the faulted circuit. This protection is provided at current levels less than those required to protect conductors from damage through the operation of a supply circuit overcurrent device.

•

See the commentary following 230.95, 426.28, and 427.22.

**Grounding Conductor, Equipment (EGC).** The conductive path(s) installed to connect normally non-current-carrying metal parts of equipment together and to the system grounded conductor or to the grounding electrode conductor, or both.

Informational Note No. 1: It is recognized that the equipment grounding conductor also performs bonding.

Informational Note No. 2: See 250.118 for a list of acceptable equipment grounding conductors.

Requirements for proper sizing of equipment grounding conductors are found in 250.122 and Table 250.122.

**Grounding Electrode.** A conducting object through which a direct connection to earth is established.

For requirements pertaining to grounding electrodes, see 250.52(A).

**Grounding Electrode Conductor.** A conductor used to connect the system grounded conductor or the equipment to a grounding electrode or to a point on the grounding electrode system.

The grounding electrode conductor, which is used at the service or a separately derived system, is covered extensively in Article 250, Part III. These conductors are required to be copper, aluminum, or copper-clad aluminum in 250.62 and to be sized according to 250.66 and Table 250.66. Exhibit 100.6 and Exhibit 250.1 show a grounding electrode conductor in a typical grounding system for a single-phase, 3-wire service.

**Guarded.** Covered, shielded, fenced, enclosed, or otherwise protected by means of suitable covers, casings, barriers, rails, screens, mats, or platforms to remove the likelihood of approach or contact by persons or objects to a point of danger.

**Guest Room.** An accommodation combining living, sleeping, sanitary, and storage facilities within a compartment.

**Guest Suite.** An accommodation with two or more contiguous rooms comprising a compartment, with or without doors between such rooms, that provides living, sleeping, sanitary, and storage facilities.

Some requirements for guest rooms in hotels, motels, and similar occupancies are found in 210.60.

**Handhole Enclosure.** An enclosure for use in underground systems, provided with an open or closed bottom, and sized to allow personnel to reach into, but not enter, for the purpose of installing, operating, or maintaining equipment or wiring or both.

Requirements for handhole enclosures are found in 314.30. Exhibit 100.12 shows the installation of one type of handhole enclosure. Handhole enclosures are required by 314.30 to be “identified” for use in underground systems.

**EXHIBIT 100.12** Example of handhole enclosure installation. (Courtesy of Quazite®/Hubbell Lenoir City, Inc.)

**Hoistway.** Any shaftway, hatchway, well hole, or other vertical opening or space in which an elevator or dumbwaiter is designed to operate.

See Article 620 for the installation of electrical equipment and wiring methods in hoistways.

**Identified (as applied to equipment).** Recognizable as suitable for the specific purpose, function, use, environment, application, and so forth, where described in a particular *Code* requirement.

Informational Note: Some examples of ways to determine suitability of equipment for a specific purpose, environment, or application include investigations by a qualified testing laboratory (listing and labeling), an inspection agency, or other organizations concerned with product evaluation.

**In Sight From (Within Sight From, Within Sight).** Where this *Code* specifies that one equipment shall be “in sight from,” “within sight from,” or “within sight of,” and so forth, another equipment, the specified equipment is to be visible and not more than 15 m (50 ft) distant from the other.

There are several requirements in the *Code* for a disconnecting means to be in sight from the equipment that it controls. For example, 430.102 requires the disconnecting means to be in sight from the controller. Three exceptions permit the disconnect to be located elsewhere. Exhibit 430.18 depicts requirements for the placement of a disconnecting means that is not in sight of a motor.

**Interactive System.** An electric power production system that is operating in parallel with and capable of delivering energy to an electric primary source supply system.

**Interrupting Rating.** The highest current at rated voltage that a device is identified to interrupt under standard test conditions.

Informational Note: Equipment intended to interrupt current at other than fault levels may have its interrupting rating implied in other ratings, such as horsepower or locked rotor current.

Interrupting ratings are essential in the coordination of electrical systems so that available fault currents can be properly controlled. Sections specifically dealing with interrupting ratings are 110.9, 240.60(C), 240.83(C), and 240.86. Exhibit 100.13 depicts the label of a 1600 amp frame circuit breaker showing the interrupting capacity ratings.

**EXHIBIT 100.13** Interrupting ratings information on the label of a 1600 ampere circuit breaker.

**Intersystem Bonding Termination.** A device that provides a means for connecting bonding conductors for communications systems to the grounding electrode system.

An intersystem bonding termination provides a convenient means to comply with the requirements for intersystem bonding and grounding of communication systems. It is a dedicated and well-defined location for terminating the grounding conductors required in Chapter 8 and 770.93. The termination would have sufficient capacity to handle multiple communication systems (telecom, satellite, CATV) on premises. The intersystem bonding termination device is intended to provide a means of connecting these grounding conductors to the service, building, or structure grounding electrode system. This is an important safety measure to prevent occurrences of voltages between the communication system and the power system. Frequently, in new construction, the grounding electrode, the raceway, and the grounding electrode conductor are hidden behind walls and are not accessible for bonding connection. See Exhibit 250.41 for an example of a device used to provide intersystem bonding.

**Isolated (as applied to location).** Not readily accessible to persons unless special means for access are used.

See also the definition of *accessible, readily*.

**Kitchen.** An area with a sink and permanent provisions for food preparation and cooking.

Because the term *kitchen* is used frequently in the *Code*, a common definition for this word is necessary so that uniform and consistent application of *Code* requirements can be established.

**Labeled.** Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

Equipment and conductors required or permitted by this *Code* are acceptable only if they have been approved for a specific environment or application by the authority having jurisdiction, as stated in 110.2. See 90.7 regarding the examination of equipment for safety. Listing or labeling by a qualified testing laboratory provides a basis for approval.

**Lighting Outlet.** An outlet intended for the direct connection of a lampholder or luminaire.

**Listed.** Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

Informational Note: The means for identifying listed equipment may vary for each organization concerned with product evaluation, some of which do not recognize equipment as listed unless it is also labeled. Use of the system employed by the listing organization allows the authority having jurisdiction to identify a listed product.

The *NEC* definition of *listed* matches the definition of *listed* found in the NFPA Regulations Governing Committee Projects. See definitions of *approved*, *authority having jurisdiction (AHJ)*, *identified (as applied to equipment)*, and *labeled*.

**Live Parts.** Energized conductive components.

The definition of *live parts* is associated with all voltage levels, not just voltage levels that present a shock hazard.

**Location, Damp.** Locations protected from weather and not subject to saturation with water or other liquids but subject to moderate degrees of moisture. Examples of such locations include partially protected locations under canopies, marquees, roofed open porches, and like locations, and interior locations subject to moderate degrees of moisture, such as some basements, some barns, and some cold-storage warehouses.

**Location, Dry.** A location not normally subject to dampness or wetness. A location classified as dry may be temporarily subject to dampness or wetness, as in the case of a building under construction.

**Location, Wet.** Installations underground or in concrete slabs or masonry in direct contact with the earth; in locations subject to saturation with water or other liquids, such as vehicle washing areas; and in unprotected locations exposed to weather.

The inside of a raceway in a wet location and a raceway installed underground are considered wet locations. Therefore, any conductors contained therein would be required to be suitable for wet locations.

A general requirement pertaining to wet locations is found in 300.6(D), which also identifies numerous examples of wet locations. The requirements for luminaires installed

in wet locations are found in 410.10(A). See also *patient care area* in 517.2 for a definition of wet procedure locations in a patient care area. Suitable enclosures for wet locations can be found in Table 110.28.

**Luminaire.** A complete lighting unit consisting of a light source such as a lamp or lamps, together with the parts designed to position the light source and connect it to the power supply. It may also include parts to protect the light source or the ballast or to distribute the light. A lampholder itself is not a luminaire.

Although new lighting techniques such as light pipes and glass fiber optics are sometimes referred to as “lighting systems,” the definition of *luminaire* does not necessarily preclude such systems, because light pipes and fiber optics are actually “parts designed to distribute the light.”

*Luminaire* is the term specified by IESNA, the ANSI/UL safety standards, and the ANSI/NEMA performance standards for lighting products previously referred to as “light fixtures” in the United States. *Luminaire* is also the term used in IEC standards and accepted globally.

**Metal-Enclosed Power Switchgear.** A switchgear assembly completely enclosed on all sides and top with sheet metal (except for ventilating openings and inspection windows) and containing primary power circuit switching, interrupting devices, or both, with buses and connections. The assembly may include control and auxiliary devices. Access to the interior of the enclosure is provided by doors, removable covers, or both. Metal-enclosed power switchgear is available in non-arc-resistant or arc-resistant constructions.

**Motor Control Center.** An assembly of one or more enclosed sections having a common power bus and principally containing motor control units.

**Multioutlet Assembly.** A type of surface, flush, or free-standing raceway designed to hold conductors and receptacles, assembled in the field or at the factory.

The definition of *multioutlet assembly* includes a reference to a freestanding assembly with multiple outlets, commonly called a power pole. In dry locations, metallic and nonmetallic multioutlet assemblies are permitted; however, they are not permitted to be installed if concealed. See Article 380 for details on recessing multioutlet assemblies. Exhibit 100.14 shows a multioutlet assembly used for countertop appliances.

**Neutral Conductor.** The conductor connected to the neutral point of a system that is intended to carry current under normal conditions.

**EXHIBIT 100.14** Multioutlet assembly installed to serve countertop appliances. (Courtesy of Legrand/Wiremold®)

This definition is similar to the IEC definition of *neutral conductor*. The proposed definition was adapted to *NEC* language and was expanded to cover the various cases relevant to the *NEC*.

It is important to remember that the neutral conductor is a current-carrying conductor. Many believe that, because the neutral conductor is a grounded conductor, it is safe to work on it while it is energized. This is a very dangerous practice that has led to many serious electric shocks.

**Neutral Point.** The common point on a wye-connection in a polyphase system or midpoint on a single-phase, 3-wire system, or midpoint of a single-phase portion of a 3-phase delta system, or a midpoint of a 3-wire, direct-current system.

**Informational Note:** At the neutral point of the system, the vectorial sum of the nominal voltages from all other phases within the system that utilize the neutral, with respect to the neutral point, is zero potential.

Exhibit 100.15 illustrates four examples of a neutral point in a system.

**Nonautomatic.** Requiring human intervention to perform a function.

A nonautomatic function is essentially a manual function.

**Nonlinear Load.** A load where the wave shape of the steady-state current does not follow the wave shape of the applied voltage.

**EXHIBIT 100.15** Four examples of a neutral point.

**Informational Note:** Electronic equipment, electronic/electric-discharge lighting, adjustable-speed drive systems, and similar equipment may be nonlinear loads.

Nonlinear loads are a major cause of harmonic currents in modern circuits. Additional conductor heating is just one of the undesirable operational effects often associated with harmonic currents. Informational Note No. 1 following 310.15(A)(3) points out that harmonic current, as well as fundamental current, should be used in determining the heat generated internally in a conductor.

Actual circuit measurements of current for nonlinear loads should be made using only true rms-measuring ammeter instruments. Averaging ammeters produces inaccurate values if used to measure nonlinear loads. See the associated commentary following 310.15(B)(5)(c).

**Outlet.** A point on the wiring system at which current is taken to supply utilization equipment.

This term is frequently misused to refer to receptacles. Although receptacle outlets are outlets, not all outlets are receptacle outlets. Common examples of outlets include lighting outlets and smoke alarm outlets.

**Outline Lighting.** An arrangement of incandescent lamps, electric-discharge lighting, or other electrically powered light sources to outline or call attention to certain features such as the shape of a building or the decoration of a window.

The definition of *outline lighting* includes low-voltage, light-emitting diodes as well as other luminaires installed to

form various shapes. See Article 600 for requirements for outline lighting.

**Overcurrent.** Any current in excess of the rated current of equipment or the ampacity of a conductor. It may result from overload, short circuit, or ground fault.

Informational Note: A current in excess of rating may be accommodated by certain equipment and conductors for a given set of conditions. Therefore, the rules for overcurrent protection are specific for particular situations.

**Overcurrent Protective Device, Branch-Circuit.** A device capable of providing protection for service, feeder, and branch circuits and equipment over the full range of overcurrents between its rated current and its interrupting rating. Branch-circuit overcurrent protective devices are provided with interrupting ratings appropriate for the intended use but no less than 5000 amperes.

The protection provided may be overload, short-circuit, or ground-fault or a combination, depending on the application. See also definition for *overcurrent protective device, supplementary*.

**Overcurrent Protective Device, Supplementary.** A device intended to provide limited overcurrent protection for specific applications and utilization equipment such as luminaires and appliances. This limited protection is in addition to the protection provided in the required branch circuit by the branch-circuit overcurrent protective device.

There are two levels of overcurrent protection within branch circuits: branch-circuit overcurrent protection and supplementary overcurrent protection. The devices used to provide overcurrent protection are different, and the differences are found in the product standards UL 489, *Molded-Case Circuit Breakers, Molded-Case Switches and Circuit-Breaker Enclosures*, and UL 1077, *Supplementary Protectors for Use in Electrical Equipment*.

The NEC requires that all branch circuits use only branch-circuit “rated” overcurrent protective devices to protect branch circuits, but it permits supplementary overcurrent protection devices for limited use downstream of the branch-circuit “rated” overcurrent protective device.

The definition of *supplementary overcurrent protection device* makes two important distinctions between overcurrent protective devices. First, the use of a supplementary device is specifically limited to a few applications. Second, where it is used, the supplementary device must be in addition to and be protected by the more robust branch-circuit overcurrent protective device.

**Overload.** Operation of equipment in excess of normal, full-load rating, or of a conductor in excess of rated ampacity that, when it persists for a sufficient length of time, would cause damage or dangerous overheating. A fault, such as a short circuit or ground fault, is not an overload.

**Panelboard.** A single panel or group of panel units designed for assembly in the form of a single panel, including buses and automatic overcurrent devices, and equipped with or without switches for the control of light, heat, or power circuits; designed to be placed in a cabinet or cutout box placed in or against a wall, partition, or other support; and accessible only from the front.

See Article 408, Parts I, III, and IV, for detailed requirements concerning panelboards.

**Plenum.** A compartment or chamber to which one or more air ducts are connected and that forms part of the air distribution system.

The NEC definition of *plenum* is essentially the same as that in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*. NEC requirements on wiring methods permitted within plenums are found in 300.22(B). The NEC definition is not intended to apply to the space above a suspended ceiling that is used for environmental air as referred to in 300.22(C), while the air-handling space under a computer room floor has special requirements, as given in Article 645.

**Power Outlet.** An enclosed assembly that may include receptacles, circuit breakers, fuseholders, fused switches, buses, and watt-hour meter mounting means; intended to supply and control power to mobile homes, recreational vehicles, park trailers, or boats or to serve as a means for distributing power required to operate mobile or temporarily installed equipment.

**Premises Wiring (System).** Interior and exterior wiring, including power, lighting, control, and signal circuit wiring together with all their associated hardware, fittings, and wiring devices, both permanently and temporarily installed. This includes (a) wiring from the service point or power source to the outlets or (b) wiring from and including the power source to the outlets where there is no service point.

Such wiring does not include wiring internal to appliances, luminaires, motors, controllers, motor control centers, and similar equipment.

**Qualified Person.** One who has skills and knowledge related to the construction and operation of the electrical equipment and installations and has received safety training to recognize and avoid the hazards involved.

Informational Note: Refer to NFPA 70E-2009, *Standard for Electrical Safety in the Workplace*, for electrical safety training requirements.

This definition points out that safety training that qualifies a worker is training in hazard recognition and avoidance. The following excerpt on training requirements is taken from 110.6 in the 2009 edition of *NFPA 70E®, Standard for Electrical Safety in the Workplace®*. These training requirements are presented here only as an aid to understanding the requisite minimum training requirements specified in *NFPA 70E*, a recognized and widely used workplace safety standard. It is important to understand that this commentary, like the informational note following the definition of *qualified person*, is not mandatory. Mandatory application of these safety training provisions is dependent on whether *NFPA 70E* has been specifically adopted by the enforcing jurisdiction.

**Excerpt from NFPA 70E®-2009, *Standard for Electrical Safety in the Workplace®***

**110.6 Training Requirements.**

**(A) Safety Training.** The training requirements contained in this section shall apply to employees who face a risk of electrical hazard that is not reduced to a safe level by the applicable electrical installation requirements. Such employees shall be trained to understand the specific hazards associated with electrical energy. They shall be trained in safety-related work practices and procedural requirements as necessary to provide protection from the electrical hazards associated with their respective job or task assignments. Employees shall be trained to identify and understand the relationship between electrical hazards and possible injury.

**(B) Type of Training.** The training required by this section shall be classroom or on-the-job type, or a combination of the two. The degree of training provided shall be determined by the risk to the employee.

**(C) Emergency Procedures.** Employees exposed to shock hazards shall be trained in methods of release of victims from contact with exposed energized electrical conductors or circuit parts. Employees shall be regularly instructed in methods of first aid and emergency procedures, such as approved methods of resuscitation, if their duties warrant such training. Training of employees in approved methods of resuscitation, including cardiopulmonary resuscitation, shall be certified by the employer annually.

**(D) Employee Training.**

**(1) Qualified Person.** A qualified person shall be trained and knowledgeable of the construction and operation of equipment or a specific work method and be trained to recognize and avoid the electrical hazards that might be present with respect to that equipment or work method.

(a) Such persons shall also be familiar with the proper use of the special precautionary techniques, per-

sonal protective equipment, including arc-flash, insulating and shielding materials, and insulated tools and test equipment. A person can be considered qualified with respect to certain equipment and methods but still be unqualified for others.

(b) Such persons permitted to work within the Limited Approach Boundary of exposed energized electrical conductors and circuit parts operating at 50 volts or more shall, at a minimum, be additionally trained in all of the following:

- (1) The skills and techniques necessary to distinguish exposed energized electrical conductors and circuit parts from other parts of electrical equipment
- (2) The skills and techniques necessary to determine the nominal voltage of exposed energized electrical conductors and circuit parts
- (3) The approach distances specified in Table 130.2(C) [of *NFPA 70E*] and the corresponding voltages to which the qualified person will be exposed
- (4) The decision-making process necessary to determine the degree and extent of the hazard and the personal protective equipment and job planning necessary to perform the task safely

(c) An employee who is undergoing on-the-job training and who, in the course of such training, has demonstrated an ability to perform duties safely at his or her level of training and who is under the direct supervision of a qualified person shall be considered to be a qualified person for the performance of those duties.

(d) Tasks that are performed less often than once per year shall require retraining before the performance of the work practices involved.

(e) Employees shall be trained to select an appropriate voltage detector and shall demonstrate how to use a device to verify the absence of voltage, including interpreting indications provided by the device. The training shall include information that enables the employee to understand all limitations of each specific voltage detector that may be used.

**(2) Unqualified Persons.** Unqualified persons shall be trained in and be familiar with any of the electrical safety-related practices that might not be addressed specifically by Chapter 1 [of *NFPA 70E*] but are necessary for their safety.

**Raceway.** An enclosed channel of metal or nonmetallic materials designed expressly for holding wires, cables, or busbars, with additional functions as permitted in this *Code*. Raceways include, but are not limited to, rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, liquidtight flexible conduit, flexible metallic tubing, flexible metal conduit, electrical nonmetallic tubing, electrical metallic tubing, underfloor raceways, cellular concrete floor raceways, cellular metal floor raceways, surface raceways, wireways, and busways.

General requirements and wiring methods for raceways are found within Article 300 and throughout Chapter 3 for more specific applications. Cable trays (see Article 392) are support systems for wiring methods and are not considered to be raceways.

**Rainproof.** Constructed, protected, or treated so as to prevent rain from interfering with the successful operation of the apparatus under specified test conditions.

See the commentary following 110.28.

**Raintight.** Constructed or protected so that exposure to a beating rain will not result in the entrance of water under specified test conditions.

Requirements for enclosures are in 110.28, and the informational note to Table 110.28 provides information on enclosure types that are considered to be raintight. Also see the commentary accompanying 110.28 for details on enclosure markings. Related requirements for raintight boxes and cabinets are found in 300.6(A)(2).

**Receptacle.** A receptacle is a contact device installed at the outlet for the connection of an attachment plug. A single receptacle is a single contact device with no other contact device on the same yoke. A multiple receptacle is two or more contact devices on the same yoke.

Exhibit 100.16 shows one single and two multiple receptacles.

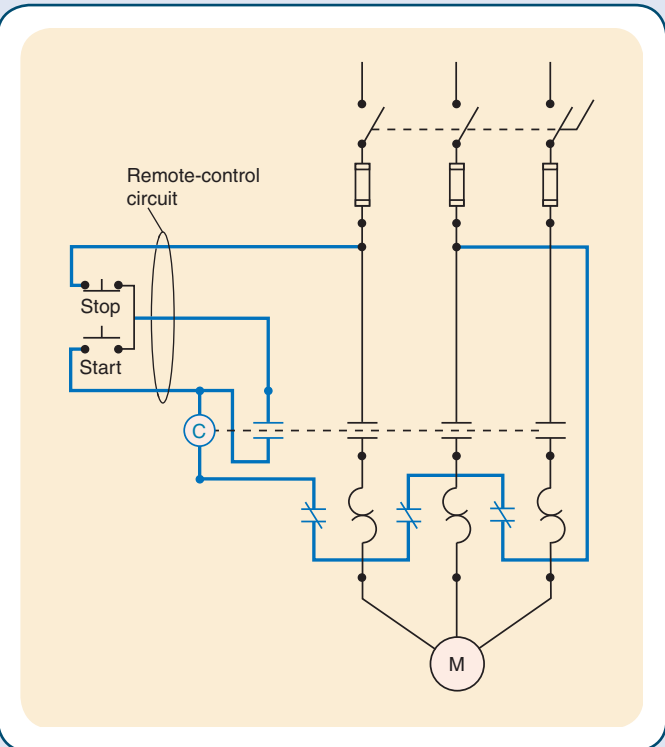

**EXHIBIT 100.16** Receptacles.

**Receptacle Outlet.** An outlet where one or more receptacles are installed.

See Exhibit 100.16 and the commentary following 220.14(I).

**Remote-Control Circuit.** Any electrical circuit that controls any other circuit through a relay or an equivalent device.

Exhibit 100.17 illustrates a remote-control circuit that starts and stops an electric motor.

**EXHIBIT 100.17** Remote-control circuit for starting and stopping an electric motor.

**Sealable Equipment.** Equipment enclosed in a case or cabinet that is provided with a means of sealing or locking so that live parts cannot be made accessible without opening the enclosure. The equipment may or may not be operable without opening the enclosure.

**Separately Derived System.** A premises wiring system whose power is derived from a source of electric energy or equipment other than a service. Such systems have no direct connection from circuit conductors of one system to circuit conductors of another system, other than connections through the earth, metal enclosures, metallic raceways, or equipment grounding conductors.

Examples of separately derived systems include generators, batteries, converter windings, transformers, and solar photo-

voltaic systems, provided they “have no direct electrical connection” to another source. This definition was revised for the 2011 *Code* to clarify the interconnection between separately derived systems and service derived electrical systems. The earth, metal enclosures, metal raceways, and equipment grounding conductors may provide incidental connection between systems. However, the grounded circuit conductors are not intended to be directly connected.

**Service.** The conductors and equipment for delivering electric energy from the serving utility to the wiring system of the premises served.

A service can only be supplied by the serving utility. If electric energy is supplied by other than the serving utility, the supplied conductors and equipment are considered feeders, not a service.

**Service Cable.** Service conductors made up in the form of a cable.

**Service Conductors.** The conductors from the service point to the service disconnecting means.

*Service conductors* is a broad term and may include service drops, service laterals, and service-entrance conductors. This term specifically excludes, however, any wiring on the supply side (serving utility side) of the service point. Simply put, the service conductors originate at the service point (where the serving utility ends) and end at the service disconnect. These service conductors may originate only from the serving utility.

If the utility has specified that the service point is at the utility pole, the service conductors from an overhead distribution system originate at the utility pole and terminate at the service disconnecting means.

If the utility has specified that the service point is at the utility manhole, the service conductors from an underground distribution system originate at the utility manhole and terminate at the service disconnecting means. Where utility-owned primary conductors are extended to outdoor pad-mounted transformers on private property, the service conductors originate at the secondary connections of the transformers only if the utility has specified that the service point is at the secondary connections.

See Article 230, Part VIII, and the commentary following 230.200 for service conductors exceeding 600 volts, nominal.

**Service Conductors, Overhead.** The overhead conductors between the service point and the first point of connection

to the service-entrance conductors at the building or other structure.

**Service Conductors, Underground.** The underground conductors between the service point and the first point of connection to the service-entrance conductors in a terminal box, meter, or other enclosure, inside or outside the building wall.

**Informational Note:** Where there is no terminal box, meter, or other enclosure, the point of connection is considered to be the point of entrance of the service conductors into the building.

**Service Drop.** The overhead conductors between the utility electric supply system and the service point.

The definition of *service drop* was revised for the 2011 *Code*. This revision correlates with the changes to the definitions of the term *service lateral conductors*. Service drop and service lateral conductors are conductors on the line side of the service point and are not subject to the *NEC*. Overhead conductors on the load side of the service point are overhead service conductors.

In Exhibit 100.18, the service-drop conductors run from the utility pole and connect to the service-entrance conductors at the service point. Conductors on the utility side of the service point are not covered by the *NEC*. The utility specifies the location of the service point. Exact locations of the service point may vary from utility to utility, as well as from occupancy to occupancy.

**EXHIBIT 100.18** Conductors in an overhead service.

**Service-Entrance Conductors, Overhead System.** The service conductors between the terminals of the service

equipment and a point usually outside the building, clear of building walls, where joined by tap or splice to the service drop or overhead service conductors.

See Exhibit 100.19 for an illustration of service-entrance conductors in an overhead system. The system shows a service drop from a utility pole to attachment on a house and service-entrance conductors from point of attachment (spliced to service-drop conductors), down the side of the house, through the meter socket, and terminating in the service equipment. In this instance, the service point is at the drip loop.

**Informational Note:** Where service equipment is located outside the building walls, there may be no service-entrance conductors or they may be entirely outside the building.

See Exhibit 100.19 for an illustration of service-entrance conductors in an underground system. The illustration on the top shows underground service lateral conductors run from a pole to a service point underground. The conductors from the service point into the building are underground service conductors. The illustration on the bottom shows service lateral conductors run from a utility transformer.

**Service Equipment.** The necessary equipment, usually consisting of a circuit breaker(s) or switch(es) and fuse(s) and their accessories, connected to the load end of service conductors to a building or other structure, or an otherwise designated area, and intended to constitute the main control and cutoff of the supply.

Service equipment may consist of circuit breakers or fused switches that are provided to disconnect all ungrounded conductors in a building or other structure from the service-entrance conductors. It is important to understand that individual meter socket enclosures are not considered service equipment according to 230.66. A case could be made that potential and current transformer cabinets associated with utility meter enclosures are also excluded from the definition of *service equipment*.

The disconnecting means at any one location in a building or other structure is not allowed to consist of more than six circuit breakers or six switches and is required to be readily accessible either outside or inside nearest the point of entrance of the service-entrance conductors. Requirements for service conductors outside the building are in 230.6 and those for disconnecting means are throughout Article 230, Part VI.

**Service Lateral.** The underground conductors between the utility electric supply system and the service point.

The definition of *service lateral* was revised for the 2011 Code. This revision correlates with the changes to the definitions of the term *service drop conductors*. Service drop and service lateral conductors are conductors on the line side of the service point and are not subject to the NEC. Underground conductors on the load side of the service point are underground service conductors.

As Exhibit 100.19 shows, the underground service laterals may be run from poles or from transformers and with or without terminal boxes, provided they terminate at the

**EXHIBIT 100.19** Underground systems showing service laterals run from a pole (top) and from a transformer (bottom).

**Service-Entrance Conductors, Underground System.** The service conductors between the terminals of the service equipment and the point of connection to the service lateral or underground service conductors.

service point. The next transition would be to the underground service conductors, which would connect to the service entrance conductors, or they may terminate in a terminal box, meter, or some other enclosure, which may be inside or outside of the building. Conductors on the utility side of the service point are not covered by the *NEC*. The utility specifies the location of the service point. Exact locations of the service point may vary from utility to utility, as well as from occupancy to occupancy.

**Service Point.** The point of connection between the facilities of the serving utility and the premises wiring.

**Informational Note:** The service point can be described as the point of demarcation between where the serving utility ends and the premises wiring begins. The serving utility generally specifies the location of the service point based on the conditions of service.

Because the location of the service point is generally determined by the utility, the overhead conductors or the underground conductors may or may not be part of the service covered by the *NEC*. For these types of conductors to be covered, they must be physically located on the premises wiring side of the service point.

Based on the definition of the term *service point* any conductor on the serving utility side of the service point generally is not covered by the *NEC*. For example, a typical suburban residence has overhead conductors from the utility pole to the house. If the utility specifies that the service point is at the point of attachment of the overhead conductors to the house, the overhead conductors are service drop conductors that are not covered by the *Code* because the conductors are not on the premises wiring side of the service point. Alternatively, if the utility specifies that the service point is “at the pole,” the overhead conductors are considered overhead service conductors, and the *NEC* would apply to these conductors.

Exact locations for a service point may vary from utility to utility, as well as from occupancy to occupancy.

**Short-Circuit Current Rating.** The prospective symmetrical fault current at a nominal voltage to which an apparatus or system is able to be connected without sustaining damage exceeding defined acceptance criteria.

The short-circuit current rating is marked on the equipment nameplate, as shown in Exhibit 100.20. This value must not be exceeded. Otherwise, the equipment can be damaged by short-circuit currents, posing a hazard to personnel and property.

**EXHIBIT 100.20** Short-circuit current rating on equipment nameplate.

**Show Window.** Any window used or designed to be used for the display of goods or advertising material, whether it is fully or partly enclosed or entirely open at the rear and whether or not it has a platform raised higher than the street floor level.

See 220.14(G), 220.43(A), and Exhibit 220.1 for show-window lighting load requirements.

**Signaling Circuit.** Any electrical circuit that energizes signaling equipment.

**Solar Photovoltaic System.** The total components and subsystems that, in combination, convert solar energy into electric energy suitable for connection to a utilization load.

See Article 690 for solar photovoltaic system requirements.

**Special Permission.** The written consent of the authority having jurisdiction.

The authority having jurisdiction for enforcement of the *Code* is responsible for making interpretations and granting special permission contemplated in a number of the rules, as

stated in 90.4. For requirements governing special permission situations, see 110.26(A)(1)(b), 230.2(B), and 426.14.

**Structure.** That which is built or constructed.

**Surge Arrester.** A protective device for limiting surge voltages by discharging or bypassing surge current; it also prevents continued flow of follow current while remaining capable of repeating these functions.

For further information on surge arresters, see Article 280.

**Surge-Protective Device (SPD).** A protective device for limiting transient voltages by diverting or limiting surge current; it also prevents continued flow of follow current while remaining capable of repeating these functions and is designated as follows:

Type 1: Permanently connected SPDs intended for installation between the secondary of the service transformer and the line side of the service disconnect overcurrent device.

Type 2: Permanently connected SPDs intended for installation on the load side of the service disconnect overcurrent device, including SPDs located at the branch panel.

Type 3: Point of utilization SPDs.

Type 4: Component SPDs, including discrete components, as well as assemblies.

Informational Note: For further information on Type 1, Type 2, Type 3, and Type 4 SPDs, see UL 1449, *Standard for Surge Protective Devices*.

Type 1 and Type 2 surge-protective devices (SPDs) for permanently connected devices for use on circuits not exceeding 600 volts are included in UL 1449, *Transient Voltage Surge Suppressors*. Requirements related to SPDs are found in Article 280.

**Switch, Bypass Isolation.** A manually operated device used in conjunction with a transfer switch to provide a means of directly connecting load conductors to a power source and of disconnecting the transfer switch.

See 700.5(B) and 701.5(B) for requirements pertaining to bypass isolation transfer switches.

**Switch, General-Use.** A switch intended for use in general distribution and branch circuits. It is rated in amperes, and it is capable of interrupting its rated current at its rated voltage.

**Switch, General-Use Snap.** A form of general-use switch constructed so that it can be installed in device boxes or on box covers, or otherwise used in conjunction with wiring systems recognized by this *Code*.

**Switch, Isolating.** A switch intended for isolating an electrical circuit from the source of power. It has no interrupting rating, and it is intended to be operated only after the circuit has been opened by some other means.

**Switch, Motor-Circuit.** A switch rated in horsepower that is capable of interrupting the maximum operating overload current of a motor of the same horsepower rating as the switch at the rated voltage.

**Switch, Transfer.** An automatic or nonautomatic device for transferring one or more load conductor connections from one power source to another.

**Switchboard.** A large single panel, frame, or assembly of panels on which are mounted on the face, back, or both, switches, overcurrent and other protective devices, buses, and usually instruments. Switchboards are generally accessible from the rear as well as from the front and are not intended to be installed in cabinets.

Busbars are required to be arranged to avoid inductive overheating. Service busbars are required to be isolated by barriers from the remainder of the switchboard. Although not required, most modern switchboards are totally enclosed to minimize the probability of spreading fire to adjacent combustible materials and to guard live parts. Requirements for switchboards are located in Article 408.

**Thermal Protector (as applied to motors).** A protective device for assembly as an integral part of a motor or motor-compressor that, when properly applied, protects the motor against dangerous overheating due to overload and failure to start.

Informational Note: The thermal protector may consist of one or more sensing elements integral with the motor or motor-compressor and an external control device.

**Thermally Protected (as applied to motors).** The words *Thermally Protected* appearing on the nameplate of a motor or motor-compressor indicate that the motor is provided with a thermal protector.

**Ungrounded.** Not connected to ground or to a conductive body that extends the ground connection.

**Uninterruptible Power Supply.** A power supply used to provide alternating current power to a load for some period of time in the event of a power failure.

Informational Note: In addition, it may provide a more constant voltage and frequency supply to the load, reducing the effects of voltage and frequency variations.

**Utility-Interactive Inverter.** An inverter intended for use in parallel with an electric utility to supply common loads that may deliver power to the utility.

**Utilization Equipment.** Equipment that utilizes electric energy for electronic, electromechanical, chemical, heating, lighting, or similar purposes.

**Ventilated.** Provided with a means to permit circulation of air sufficient to remove an excess of heat, fumes, or vapors.

See the commentary following 110.13(B).

**Volatile Flammable Liquid.** A flammable liquid having a flash point below 38°C (100°F), or a flammable liquid whose temperature is above its flash point, or a Class II combustible liquid that has a vapor pressure not exceeding 276 kPa (40 psia) at 38°C (100°F) and whose temperature is above its flash point.

The flash point of a liquid is defined as the minimum temperature at which it gives off sufficient vapor to form an ignitable mixture, with the air near the surface of the liquid or within the vessel used to contain the liquid. An ignitable mixture is defined as a mixture within the explosive or flammable range (between upper and lower limits) that is capable of the propagation of flame away from the source of ignition when ignited. Some emission of vapors takes place below the flash point but not in sufficient quantities to form an ignitable mixture.

**Voltage (of a circuit).** The greatest root-mean-square (rms) (effective) difference of potential between any two conductors of the circuit concerned.

Informational Note: Some systems, such as 3-phase 4-wire, single-phase 3-wire, and 3-wire direct current, may have various circuits of various voltages.

Common 3-phase, 4-wire wye systems are 480/277 volts and 208/120 volts. The voltage of the circuit is the higher voltage between any two phase conductors (i.e., 480 volts or 208 volts). The voltage of the circuit of a 2-wire feeder or branch circuit (single phase and the grounded conductor) derived from these systems would be the lower voltage between two conductors (i.e., 277 volts or 120 volts). The same applies to dc or single-phase, 3-wire systems where there are two voltages.

**Voltage, Nominal.** A nominal value assigned to a circuit or system for the purpose of conveniently designating its voltage class (e.g., 120/240 volts, 480Y/277 volts, 600 volts). The actual voltage at which a circuit operates can vary from the nominal within a range that permits satisfactory operation of equipment.

Informational Note: See ANSI C84.1-2006, *Voltage Ratings for Electric Power Systems and Equipment* (60 Hz).

For a list of nominal voltages to use in computing branch-circuit and feeder loads, see 220.5(A).

**Voltage to Ground.** For grounded circuits, the voltage between the given conductor and that point or conductor of the circuit that is grounded; for ungrounded circuits, the greatest voltage between the given conductor and any other conductor of the circuit.

The voltage to ground of a 480/277-volt wye system would be 277 volts; of a 208/120-volt wye system, 120 volts; and of a 3-phase, 3-wire ungrounded 480-volt system, 480 volts.

For a 3-phase, 4-wire delta system with the center of one leg grounded, there are three voltages to ground — that is, on a 240-volt system, two legs would each have 120 volts to ground, and the third, or “high,” leg would have 208 volts to ground. See 110.15, 230.56, and 408.3(E) for requirements pertaining to special markings and arrangements on such circuit conductors.

**Watertight.** Constructed so that moisture will not enter the enclosure under specified test conditions.

Unless an enclosure is hermetically sealed, it is possible for moisture to enter the enclosure. See the requirements related to watertight enclosures in 110.28 and Table 110.28 and the additional information given in the accompanying commentary.

**Weatherproof.** Constructed or protected so that exposure to the weather will not interfere with successful operation.

Informational Note: Rainproof, raintight, or watertight equipment can fulfill the requirements for weatherproof where varying weather conditions other than wetness, such as snow, ice, dust, or temperature extremes, are not a factor.

For requirements and more information on enclosures considered to be weatherproof based on exposure to specific environmental conditions, see 110.28 and the accompanying commentary, as well as Table 110.28 and its informational note.

## II. Over 600 Volts, Nominal

Whereas the preceding definitions are intended to apply wherever the terms are used throughout this *Code*, the following definitions are applicable only to parts of the article specifically covering installations and equipment operating at over 600 volts, nominal.

**Electronically Actuated Fuse.** An overcurrent protective device that generally consists of a control module that provides current sensing, electronically derived time–current characteristics, energy to initiate tripping, and an interrupting module that interrupts current when an overcurrent occurs. Electronically actuated fuses may or may not operate in a current-limiting fashion, depending on the type of control selected.

Although they are called fuses because they interrupt current by melting a fusible element, electronically actuated fuses respond to a signal from an electronic control rather than from the heat generated by actual current passing through a fusible element. Electronically actuated fuses have controls similar to those of electronic circuit breakers.

**Fuse.** An overcurrent protective device with a circuit-opening fusible part that is heated and severed by the passage of overcurrent through it.

**Informational Note:** A fuse comprises all the parts that form a unit capable of performing the prescribed functions. It may or may not be the complete device necessary to connect it into an electrical circuit.

**Controlled Vented Power Fuse.** A fuse with provision for controlling discharge circuit interruption such that no solid material may be exhausted into the surrounding atmosphere.

**Informational Note:** The fuse is designed so that discharged gases will not ignite or damage insulation in the path of the discharge or propagate a flashover to or between grounded members or conduction members in the path of the discharge where the distance between the vent and such insulation or conduction members conforms to manufacturer's recommendations.

**Expulsion Fuse Unit (Expulsion Fuse).** A vented fuse unit in which the expulsion effect of gases produced by the arc and lining of the fuseholder, either alone or aided by a spring, extinguishes the arc.

**Nonvented Power Fuse.** A fuse without intentional provision for the escape of arc gases, liquids, or solid particles to the atmosphere during circuit interruption.

**Power Fuse Unit.** A vented, nonvented, or controlled vented fuse unit in which the arc is extinguished by being drawn through solid material, granular material, or liquid, either alone or aided by a spring.

**Vented Power Fuse.** A fuse with provision for the escape of arc gases, liquids, or solid particles to the surrounding atmosphere during circuit interruption.

**Multiple Fuse.** An assembly of two or more single-pole fuses.

**Switching Device.** A device designed to close, open, or both, one or more electrical circuits.

**Circuit Breaker.** A switching device capable of making, carrying, and interrupting currents under normal circuit conditions, and also of making, carrying for a specified time, and interrupting currents under specified abnormal circuit conditions, such as those of short circuit.

**Cutout.** An assembly of a fuse support with either a fuseholder, fuse carrier, or disconnecting blade. The fuseholder or fuse carrier may include a conducting element (fuse link) or may act as the disconnecting blade by the inclusion of a nonfusible member.

**Disconnecting Means.** A device, group of devices, or other means whereby the conductors of a circuit can be disconnected from their source of supply.

**Disconnecting (or Isolating) Switch (Disconnecter, Isolator).** A mechanical switching device used for isolating a circuit or equipment from a source of power.

**Interrupter Switch.** A switch capable of making, carrying, and interrupting specified currents.

**Oil Cutout (Oil-Filled Cutout).** A cutout in which all or part of the fuse support and its fuse link or disconnecting blade is mounted in oil with complete immersion of the contacts and the fusible portion of the conducting element (fuse link) so that arc interruption by severing of the fuse link or by opening of the contacts will occur under oil.

**Oil Switch.** A switch having contacts that operate under oil (or askarel or other suitable liquid).

**Regulator Bypass Switch.** A specific device or combination of devices designed to bypass a regulator.

## I. General

### 110.1 Scope

This article covers general requirements for the examination and approval, installation and use, access to and spaces about electrical conductors and equipment; enclosures intended for personnel entry; and tunnel installations.

### 110.2 Approval

The conductors and equipment required or permitted by this *Code* shall be acceptable only if approved.

Informational Note: See 90.7, Examination of Equipment for Safety, and 110.3, Examination, Identification, Installation, and Use of Equipment. See definitions of *Approved*, *Identified*, *Labeled*, and *Listed*.

All electrical equipment is required to be approved and to be acceptable to the authority having jurisdiction (defined in Article 100). Approval of equipment is the responsibility of the electrical inspection authority, and many such approvals are based on tests and listings of testing laboratories. Unique equipment is often approved following a field evaluation by a qualified third-party laboratory or qualified individual.

### 110.3 Examination, Identification, Installation, and Use of Equipment

Section 110.3 provides criteria and considerations for the evaluation of equipment and recognizes listing or labeling as a means of establishing suitability. In itself, 110.3 does not require listing or labeling of equipment. It does, however, require considerable evaluation of equipment. Section 110.2 requires that equipment be acceptable only if approved. Before issuing approval, the authority having jurisdiction may require evidence of compliance with 110.3(A). The most common form of evidence considered acceptable by authorities having jurisdiction is a listing or labeling by a third party.

For wire-bending and connection space in cabinets and cutout boxes, see 312.6, Table 312.6(A), Table 312.6(B), 312.7, 312.9, and 312.11. For wire-bending and connection space in other equipment, see the appropriate *NEC* article and section. For example, see 314.16 and 314.28 for outlet, device, pull, and junction boxes, as well as conduit bodies; 404.3 and 404.18 for switches; 408.3(F) for switchboards and panelboards; and 430.10 for motors and motor controllers.

**(A) Examination.** In judging equipment, considerations such as the following shall be evaluated:

- (1) Suitability for installation and use in conformity with the provisions of this *Code*

Informational Note: Suitability of equipment use may be identified by a description marked on or provided with a product to identify the suitability of the product for a specific purpose, environment, or application. Special conditions of use or other limitations and other pertinent information may be marked on the equipment, included in the product instructions, or included in the appropriate listing and labeling information. Suitability of equipment may be evidenced by listing or labeling.

This informational note, revised for the 2011 *Code*, points out the need to address any special conditions of use that may be essential to safe use or proper functioning of the equipment. Examples of special conditions of use include the following: elevated or reduced ambient temperatures; special environmental limitations; stringent power quality requirements; or specific types of overcurrent protective devices. The additional information needed for these special cases may be marked on the equipment, or it may be included as part of the listing information in a listing directory. It may also be included in the information furnished with the equipment.

- (2) Mechanical strength and durability, including, for parts designed to enclose and protect other equipment, the adequacy of the protection thus provided
- (3) Wire-bending and connection space
- (4) Electrical insulation
- (5) Heating effects under normal conditions of use and also under abnormal conditions likely to arise in service
- (6) Arcing effects
- (7) Classification by type, size, voltage, current capacity, and specific use
- (8) Other factors that contribute to the practical safeguarding of persons using or likely to come in contact with the equipment

**(B) Installation and Use.** Listed or labeled equipment shall be installed and used in accordance with any instructions included in the listing or labeling.

This section requires manufacturers' listing and labeling installation instructions be followed even if the equipment itself is not required to be listed. For example, 210.52, second paragraph, permits permanently installed electric baseboard heaters to be equipped with receptacle outlets that meet the requirements for the wall space utilized by such heaters. The installation instructions for such permanent baseboard heaters indicate that the heaters should not be mounted beneath a receptacle. In dwelling units, it is common to use low-density heating units that measure in excess of 12 ft in length. Therefore, to meet the requirements of 210.52(A) and also the installation instructions, a receptacle must either be part of the

heating unit or be installed in the floor close to the wall but not above the heating unit. (See 210.52, informational note, and Exhibit 210.26 for more specific details.)

In itself, 110.3(B) does not require listing or labeling of equipment. It does, however, require considerable evaluation of equipment. Section 110.2 requires that equipment be acceptable only if approved. The term *approved* is defined in Article 100 as acceptable to the authority having jurisdiction (AHJ). Before issuing approval, the authority having jurisdiction may require evidence of compliance with 110.3(A). The most common form of evidence considered acceptable by authorities having jurisdiction is a listing or labeling by a third party.

Some sections in the *Code* do require listed or labeled equipment. For example, 250.8 specifies “listed pressure connectors, pressure connectors listed as grounding and bonding equipment, or other listed means” as connection methods for grounding and bonding conductors.

### 110.4 Voltages

Throughout this *Code*, the voltage considered shall be that at which the circuit operates. The voltage rating of electrical equipment shall not be less than the nominal voltage of a circuit to which it is connected.

Voltages used for computing branch-circuit and feeder loads in accordance with Article 220 are nominal voltages as specified in 220.5. See the definitions of *voltage (of a circuit)*; *voltage, nominal*; and *voltage to ground* in Article 100. See also 300.2 and 300.3(C), which specify the voltage limitations of conductors of circuits rated 600 volts, nominal, or less, and over 600 volts, nominal.

### 110.5 Conductors

Conductors normally used to carry current shall be of copper unless otherwise provided in this *Code*. Where the conductor material is not specified, the material and the sizes given in this *Code* shall apply to copper conductors. Where other materials are used, the size shall be changed accordingly.

Informational Note: For aluminum and copper-clad aluminum conductors, see 310.15.

See 310.106(B), which specifies the alloy for aluminum conductors.

### 110.6 Conductor Sizes

Conductor sizes are expressed in American Wire Gage (AWG) or in circular mils.

For copper, aluminum, or copper-clad aluminum conductors up to size 4/0 AWG, this *Code* uses the American Wire Gage (AWG) for size identification, which is the same as the Brown and Sharpe (BS) Gage. Wire sizes up to size 4/0 AWG are expressed as XX AWG, with XX being the size wire. For example, a wire size expressed as *No. 12* before the 2002 edition is expressed as *12 AWG*. The resulting expression would therefore appear as *six 12 AWG conductors*.

Conductors larger than 4/0 AWG are sized in circular mils, beginning with 250,000 circular mils. Prior to the 1990 edition, a 250,000-circular-mil conductor was labeled *250 MCM*. The term *MCM* was defined as 1000 circular mils (the first *M* being the roman numeral designation for 1000). Beginning in the 1990 edition, the notation was changed to *250 kcmil* to recognize the accepted convention that *k* indicates 1000. UL standards and IEEE standards also use the notation *kcmil* rather than *MCM*.

#### Calculation Example

The circular mil area of a conductor is equal to its diameter in mils squared (1 in. = 1000 mils). What is the circular mil area of an 8 AWG solid conductor that has a 0.1285-in. diameter?

#### Solution

$$0.1285 \text{ in.} \times 1000 = 128.5 \text{ mils}$$

$$128.5 \times 128.5 = 16,512.25 \text{ circular mils}$$

or 16,510 circular mils (rounded off)

According to Table 8 in Chapter 9, this rounded value represents the circular mil area for one conductor. Where stranded conductors are used, the circular mil area of each strand must be multiplied by the number of strands to determine the circular mil area of the conductor.

### 110.7 Wiring Integrity

Completed wiring installations shall be free from short circuits, ground faults, or any connections to ground other than as required or permitted elsewhere in this *Code*.

Failure of the insulation system is one of the most common causes of problems in electrical installations, in both high-voltage and low-voltage systems. The principal causes of insulation failures are heat, moisture, dirt, and physical damage (abrasion or nicks) occurring during and after installation. Insulation can also fail due to chemical attack, sunlight, and excessive voltage stresses.

Overcurrent protective devices must be selected and coordinated using tables of insulation thermal-withstand ability to ensure that the damage point of an insulated conductor is never reached. These tables, entitled “Allowable Short-Circuit Currents for Insulated Copper (or Aluminum)

Conductors,” are contained in the Insulated Cable Engineers Association’s publication ICEA P-32-382. See 110.10 for other circuit components.

Insulation tests are performed on new or existing installations to determine the quality or condition of the insulation of conductors and equipment. In an insulation resistance test, a voltage ranging from 100 to 5000 (usually 500 to 1000 volts for systems of 600 volts or less), supplied from a source of constant potential, is applied across the insulation. A megohmmeter is usually the potential source, and it indicates the insulation resistance directly on a scale calibrated in megohms (M $\Omega$ ). The quality of the insulation is evaluated based on the level of the insulation resistance.

The insulation resistance of many types of insulation varies with temperature, so the field data obtained should be corrected to the standard temperature for the class of equipment being tested. The megohm value of insulation resistance obtained is inversely proportional to the volume of insulation tested. For example, a cable 1000 ft long would be expected to have one-tenth the insulation resistance of a cable 100 ft long if all other conditions are identical.

NFPA 70B, *Recommended Practice for Electrical Equipment Maintenance*, provides useful information on test methods and on establishing a preventive maintenance program. Information on specific test methods is available from instrument manufacturers. Thorough knowledge in the use of insulation testers is essential if the test results are to be meaningful. Exhibit 110.1 shows a typical megohmmeter insulation tester.

## 110.8 Wiring Methods

Only wiring methods recognized as suitable are included in this *Code*. The recognized methods of wiring shall be permitted to be installed in any type of building or occupancy, except as otherwise provided in this *Code*.

Article 300 applies generally to all wiring methods, except as amended, modified, or supplemented by other *NEC* chapters. The application statement is found in 90.3, Code Arrangement.

## 110.9 Interrupting Rating

Equipment intended to interrupt current at fault levels shall have an interrupting rating **not less than** the nominal circuit voltage and the current that is available at the line terminals of the equipment.

Equipment intended to interrupt current at other than fault levels shall have an interrupting rating at nominal circuit voltage **not less than** the current that must be interrupted.

**EXHIBIT 110.1** A manual multivoltage, multirange insulation tester.

Section 110.9 requires that all fuses and circuit breakers intended to interrupt a circuit at fault levels have an adequate interrupting rating wherever they are used in the electrical system. Fuses or circuit breakers that do not have adequate interrupting ratings could rupture while attempting to clear a short circuit. The interrupting rating of overcurrent protective devices is determined under standard test conditions that should match the actual installation needs.

Interrupting ratings should not be confused with short-circuit current ratings. Short-circuit current ratings are further explained in the commentary following 110.10.

## 110.10 Circuit Impedance, Short-Circuit Current Ratings, and Other Characteristics

The overcurrent protective devices, the total impedance, the **equipment** short-circuit current ratings, and other characteristics of the circuit to be protected shall be selected and coordinated to permit the **circuit protective** devices used to clear a fault to do so without extensive damage to the electrical **equipment** of the circuit. This fault shall be assumed to be either between two or more of the circuit conductors or between any circuit conductor and the **equipment** grounding conductor(s) permitted in 250.118. Listed **equipment** applied in accordance with their listing shall be considered to meet the requirements of this section.

Short-circuit current ratings are marked on equipment such as panelboards, switchboards, busways, contactors, and starters. Listed products are tested and are subjected to rigorous testing as part of their evaluation, which includes tests under fault conditions. Therefore, listed products used within their ratings are considered to have met the requirements of 110.10.

The basic purpose of overcurrent protection is to open the circuit before conductors or conductor insulation is damaged when an overcurrent condition occurs. An overcurrent condition can be the result of an overload, a ground fault, or a short.

Overcurrent protective devices (such as fuses and circuit breakers) should be selected to ensure that the short-circuit current rating of the system components is not exceeded should a short circuit or high-level ground fault occur.

Wire, bus structures, switching, protection and disconnect devices, and distribution equipment all have limited short-circuit ratings and would be damaged or destroyed if those short-circuit ratings were exceeded. Merely providing overcurrent protective devices with sufficient interrupting ratings would not ensure adequate short-circuit protection for the system components. When the available short-circuit current exceeds the short-circuit current rating of an electrical component, the overcurrent protective device must limit the let-through energy to within the rating of that electrical component.

Utility companies usually determine and provide information on available short-circuit current levels at the service equipment. Literature on how to calculate short-circuit currents at each point in any distribution generally can be obtained by contacting the manufacturers of overcurrent protective devices or by referring to IEEE 141-1993 (R1999), *IEEE Recommended Practice for Electric Power Distribution for Industrial Plants* (Red Book).

Adequate short-circuit protection can be provided by fuses, molded-case circuit breakers, and low-voltage power circuit breakers, depending on specific circuit and installation requirements.

#### Application Example

For a typical one-family dwelling with a 100-ampere service using 2 AWG aluminum supplied by a 37½ kVA transformer with 1.72 percent impedance located at a distance of 25 ft, the available short-circuit current would be approximately 6000 amperes.

Available short-circuit current to multifamily structures, where pad-mounted transformers are located close to the multimetering location, can be relatively high. For example, the line-to-line fault current values close to a low-impedance transformer could exceed 22,000 amperes. At the secondary

of a single-phase, center-tapped transformer, the line-to-neutral fault current is approximately one and one-half times that of the line-to-line fault current. The short-circuit current rating of utilization equipment located and connected near the service equipment should be known. For example, HVAC equipment is tested at 3500 amperes through a 40-ampere load rating and at 5000 amperes for loads rated more than 40 amperes.

### 110.11 Deteriorating Agents

Unless identified for use in the operating environment, no conductors or equipment shall be located in damp or wet locations; where exposed to gases, fumes, vapors, liquids, or other agents that have a deteriorating effect on the conductors or equipment; or where exposed to excessive temperatures.

Informational Note No. 1: See 300.6 for protection against corrosion.

Informational Note No. 2: Some cleaning and lubricating compounds can cause severe deterioration of many plastic materials used for insulating and structural applications in equipment.

Equipment not identified for outdoor use and equipment identified only for indoor use, such as “dry locations,” “indoor use only,” “damp locations,” or enclosure Types 1, 2, 5, 12, 12K, and/or 13, shall be protected against damage from the weather during construction.

Informational Note No. 3: See Table 110.28 for appropriate enclosure-type designations.

This section requires that several enclosure types be protected from the weather during construction.

### 110.12 Mechanical Execution of Work

Electrical equipment shall be installed in a neat and workmanlike manner.

Informational Note: Accepted industry practices are described in ANSI/NECA 1-2006, *Standard Practices for Good Workmanship in Electrical Contracting*, and other ANSI-approved installation standards.

The requirement for “neat and workmanlike” installations has appeared in the *NEC* as currently worded for more than a half-century. It stands as a basis for pride in one’s work and has been emphasized by persons involved in the training of apprentice electricians for many years.

Many *Code* conflicts or violations have been cited by the authority having jurisdiction based on the authority’s interpretation of “neat and workmanlike manner.” Many

electrical inspection authorities use their own experience or precedents in their local areas as the basis for their judgments. The informational note directs the user to an industry-accepted ANSI standard that clearly describes and illustrates “neat and workmanlike” electrical installations. See Exhibit 110.2.

NECA 1-2010

Standard for

## Good Workmanship in Electrical Construction

AN AMERICAN NATIONAL STANDARD

NECA Published by  
National Electrical Contractors Association

**EXHIBIT 110.2** ANSI/NECA 1-2010, Standard Practice for Good Workmanship in Electrical Construction, *one example of the many ANSI standards that describe “neat and workmanlike” installations.* (Courtesy of the National Electrical Contractors Association)

### Application Example

Installations that do not qualify as “neat and workmanlike” include exposed runs of cables or raceways that are improperly supported (e.g., sagging between supports or use of improper support methods); field-bent and kinked, flattened, or poorly measured raceways; or cabinets, cutout boxes, and enclosures that are not plumb or not properly secured.

**(A) Unused Openings.** Unused openings, other than those intended for the operation of equipment, those intended for mounting purposes, or those permitted as part of the design for listed equipment, shall be closed to afford protection substantially equivalent to the wall of the equipment. Where

metallic plugs or plates are used with nonmetallic enclosures, they shall be recessed at least 6 mm ( $\frac{1}{4}$  in.) from the outer surface of the enclosure.

This section requires all *unused openings* other than those openings used for mounting, cooling, or drainage to be closed up.

See 408.7 for requirements on unused openings in switchboard and panelboard enclosures.

### **(B) Integrity of Electrical Equipment and Connections.**

Internal parts of electrical equipment, including busbars, wiring terminals, insulators, and other surfaces, shall not be damaged or contaminated by foreign materials such as paint, plaster, cleaners, abrasives, or corrosive residues. There shall be no damaged parts that may adversely affect safe operation or mechanical strength of the equipment such as parts that are broken; bent; cut; or deteriorated by corrosion, chemical action, or overheating.

## 110.13 Mounting and Cooling of Equipment

**(A) Mounting.** Electrical equipment shall be firmly secured to the surface on which it is mounted. Wooden plugs driven into holes in masonry, concrete, plaster, or similar materials shall not be used.

**(B) Cooling.** Electrical equipment that depends on the natural circulation of air and convection principles for cooling of exposed surfaces shall be installed so that room airflow over such surfaces is not prevented by walls or by adjacent installed equipment. For equipment designed for floor mounting, clearance between top surfaces and adjacent surfaces shall be provided to dissipate rising warm air.

Electrical equipment provided with ventilating openings shall be installed so that walls or other obstructions do not prevent the free circulation of air through the equipment.

*Ventilated* is defined in Article 100. Panelboards, transformers, and other types of equipment are adversely affected if enclosure surfaces normally exposed to room air are covered or tightly enclosed. Ventilating openings in equipment are provided to allow the circulation of room air around internal components of the equipment; the blocking of such openings can cause dangerous overheating. For example, a ventilated busway must be located where there are no walls or other objects that might interfere with the natural circulation of air and convection principles for cooling. Ventilation for motor locations is covered in 430.14(A) and 430.16. Ventilation for transformer locations is covered in 450.9 and 450.45. In addition to 110.13, proper placement of equipment requiring ventilation becomes enforceable using the requirements of 110.3(B).

This section requires that panelboards, transformers, and other types of equipment be located so that ventilation openings in the equipment are not blocked. To avoid dangerous overheating, these openings are provided to allow the circulation of room air around internal components of the equipment. As an example, a ventilated busway must not be located where walls or other objects might interfere with the natural circulation of air and convection principles for cooling.

### 110.14 Electrical Connections

Because of different characteristics of dissimilar metals, devices such as pressure terminal or pressure splicing connectors and soldering lugs shall be identified for the material of the conductor and shall be properly installed and used. Conductors of dissimilar metals shall not be intermixed in a terminal or splicing connector where physical contact occurs between dissimilar conductors (such as copper and aluminum, copper and copper-clad aluminum, or aluminum and copper-clad aluminum), unless the device is identified for the purpose and conditions of use. Materials such as solder, fluxes, inhibitors, and compounds, where employed, shall be suitable for the use and shall be of a type that will not adversely affect the conductors, installation, or equipment.

Connectors and terminals for conductors more finely stranded than Class B and Class C stranding as shown in Chapter 9, Table 10, shall be identified for the specific conductor class or classes.

Informational Note: Many terminations and equipment are marked with a tightening torque.

Section 110.3(B) requires the manufacturer's installation instructions be followed for listed equipment. This requirement applies where terminations and equipment are marked with tightening torques.

For the testing of wire connectors for which the manufacturer has not assigned another value appropriate for the design, Informative Annex I provides data on the tightening torques from UL 468 A-B, *Wire Connectors*. These tables should be used for guidance only if no tightening information on a specific wire connector is available. They should not be used to replace the manufacturer's instructions, which should always be followed.

This section was revised to add requirements for termination of stranded conductors. UL 486 A-B refers to conductor stranding by class. Terminals and connectors for conductors that are more finely stranded than Class B and C stranding are now required to be identified for the class or classes of conductor stranding and the number of strands. The added paragraph is consistent with 10.12 of UL 486A-B,

which requires that connectors for other than Class B or C stranding be marked with the conductor class and the number of strands. Table 10 in Chapter 9 was added to provide information for the application of this information in the field.

**(A) Terminals.** Connection of conductors to terminal parts shall ensure a thoroughly good connection without damaging the conductors and shall be made by means of pressure connectors (including set-screw type), solder lugs, or splices to flexible leads. Connection by means of wire-binding screws or studs and nuts that have upturned lugs or the equivalent shall be permitted for 10 AWG or smaller conductors.

Terminals for more than one conductor and terminals used to connect aluminum shall be so identified.

**(B) Splices.** Conductors shall be spliced or joined with splicing devices identified for the use or by brazing, welding, or soldering with a fusible metal or alloy. Soldered splices shall first be spliced or joined so as to be mechanically and electrically secure without solder and then be soldered. All splices and joints and the free ends of conductors shall be covered with an insulation equivalent to that of the conductors or with an insulating device identified for the purpose.

Wire connectors or splicing means installed on conductors for direct burial shall be listed for such use.

Field observations and trade magazine articles indicate that electrical connection failures have been determined to be the cause of many equipment burnouts and fires. Many of these failures are attributable to improper terminations, poor workmanship, the differing characteristics of dissimilar metals, and improper binding screws or splicing devices.

UL's requirements for listing solid aluminum conductors in 12 AWG and 10 AWG and for listing snap switches and receptacles for use on 15- and 20-ampere branch circuits incorporate stringent tests that take into account the factors listed in the preceding paragraph. For further information regarding receptacles and switches using CO/ALR-rated terminals, refer to 404.14(C) and 406.3(C).

Screwless pressure terminal connectors of the conductor push-in type are for use only with solid copper and copper-clad aluminum conductors.

Instructions that describe proper installation techniques and emphasize the need to follow those techniques and practice good workmanship are required to be included with each coil of 12 AWG and 10 AWG insulated aluminum wire or cable. See also the commentary on tightening torque that follows 110.14, informational note.

New product and material designs that provide increased levels of safety of aluminum wire terminations have been developed by the electrical industry. To assist all

concerned parties in the proper and safe use of solid aluminum wire in making connections to wiring devices used on 15- and 20-ampere branch circuits, the following information is presented. Understanding and using this information is essential for proper application of materials and devices now available.

### FOR NEW INSTALLATIONS

The following commentary is based on a report prepared by the Ad Hoc Committee on Aluminum Terminations prior to publication of the 1975 *Code*. This information is still pertinent today and is necessary for compliance with 110.14(A) when aluminum wire is used in new installations. New installation of aluminum conductors on 15- and 20-ampere branch circuits are not common. However, many of these circuits continue to be in use.

### New Materials and Devices

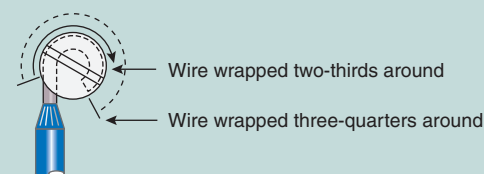

For direct connection, only 15- and 20-ampere receptacles and switches marked “CO/ALR” and connected as follows under Installation Method should be used. The “CO/ALR” marking is on the device mounting yoke or strap. The “CO/ALR” marking means the devices have been tested to stringent heat-cycling requirements to determine their suitability for use with UL-labeled aluminum, copper, or copper-clad aluminum wire.

Listed solid aluminum wire, 12 AWG or 10 AWG, marked with the aluminum insulated wire label should be used. The installation instructions that are packaged with the wire should be used.

### Installation Method

Exhibit 110.3 illustrates the following correct method of connection:

1. The freshly stripped end of the wire is wrapped two-thirds to three-quarters of the distance around the wire-binding screw post, as shown in Step A of Exhibit 110.3. The loop is made so that rotation of the screw during tightening will tend to wrap the wire around the post rather than unwrap it.
2. The screw is tightened until the wire is snugly in contact with the underside of the screw head and with the contact plate on the wiring device, as shown in Step B of Exhibit 110.3.
3. The screw is tightened an additional half-turn, thereby providing a firm connection, as shown in Step C of Exhibit 110.3. If a torque screwdriver is used, the screw is tightened to 12 lb-in.
4. The wires should be positioned behind the wiring device to decrease the likelihood of the terminal screws loosening when the device is positioned into the outlet box.

Step A: Strip Insulation and Wrap Wire

Step B: Tighten Screw to Full Contact

Step C: Complete Installation

**EXHIBIT 110.3** Correct method of terminating aluminum wire at wire-binding screw terminals of receptacles and snap switches. (Courtesy of Underwriters Laboratories Inc.)

Exhibit 110.4 illustrates incorrect methods of connection. These methods should *not* be used.

### Existing Inventory

Labeled 12 AWG or 10 AWG solid aluminum wire that does not bear the new aluminum wire label should be used with wiring devices marked “CO/ALR” and connected as described under Installation Method. This is the preferred and recommended method for using such wire.

For the following types of devices, the terminals should not be directly connected to aluminum conductors but may be used with labeled copper or copper-clad conductors:

1. Receptacles and snap switches marked “AL-CU”
2. Receptacles and snap switches having no conductor marking
3. Receptacles and snap switches that have back-wired terminals or screwless terminals of the push-in type

### FOR EXISTING INSTALLATIONS

If examination discloses overheating or loose connections, the recommendations described under Existing Inventory should be followed.

### Twist-On Wire Connectors

Because 110.14(B) requires conductors to be spliced with “splicing devices identified for the use,” wire connectors are required to be marked for conductor suitability. Twist-on

**EXHIBIT 110.4** *Incorrect methods of terminating aluminum wire at wire-binding screw terminals of receptacles and snap switches. (Courtesy of Underwriters Laboratories Inc.)*

wire connectors are not suitable for splicing aluminum conductors or copper-clad aluminum to copper conductors unless it is so stated and marked as such on the shipping carton. The marking is typically “AL-CU (dry locations).” Presently, one style of wire nut and one style of crimp-type connector have been listed as having met these requirements.

Underwriters Laboratories lists twist-on wire connectors that are suitable for use with aluminum-to-copper conductors, in accordance with UL 486C, *Splicing Wire Connectors*. The UL listing does *not* cover aluminum-to-aluminum combinations. However, more than one aluminum or copper conductor is allowed when used in combination. These listed wire-connecting devices are available for pig-tailing short lengths of copper conductors to the original aluminum branch-circuit conductors, as shown in Exhibit 110.5. Primarily, these pigtailed conductors supply 15- and 20-ampere wiring devices. Pig-tailing is permitted, provided there is suitable space within the enclosure.

**(C) Temperature Limitations.** The temperature rating associated with the ampacity of a conductor shall be selected and coordinated so as not to exceed the lowest temperature rating of any connected termination, conductor, or device. Conductors with temperature ratings higher than specified for terminations shall be permitted to be used for ampacity adjustment, correction, or both.

**EXHIBIT 110.5** *Pig-tailing copper to aluminum conductors using two listed devices.*

**(1) Equipment Provisions.** The determination of termination provisions of equipment shall be based on 110.14(C)(1) (a) or (C)(1)(b). Unless the equipment is listed and marked otherwise, conductor ampacities used in determining equipment termination provisions shall be based on [Table 310.15\(B\)\(16\)](#) as appropriately modified by 310.15(B)(7).

(a) Termination provisions of equipment for circuits rated 100 amperes or less, or marked for 14 AWG through 1 AWG conductors, shall be used only for one of the following:

- (1) Conductors rated 60°C (140°F).
- (2) Conductors with higher temperature ratings, provided the ampacity of such conductors is determined based on the 60°C (140°F) ampacity of the conductor size used.
- (3) Conductors with higher temperature ratings if the equipment is listed and identified for use with such conductors.
- (4) For motors marked with design letters B, C, or D, conductors having an insulation rating of 75°C (167°F) or higher shall be permitted to be used, provided the ampacity of such conductors does not exceed the 75°C (167°F) ampacity.

(b) Termination provisions of equipment for circuits rated over 100 amperes, or marked for conductors larger than 1 AWG, shall be used only for one of the following:

- (1) Conductors rated 75°C (167°F)
- (2) Conductors with higher temperature ratings, provided the ampacity of such conductors does not exceed the 75°C (167°F) ampacity of the conductor size used, or up to their ampacity if the equipment is listed and identified for use with such conductors

**(2) Separate Connector Provisions.** Separately installed pressure connectors shall be used with conductors at the ampacities not exceeding the ampacity at the listed and identified temperature rating of the connector.

Informational Note: With respect to 110.14(C)(1) and (C)(2), equipment markings or listing information may additionally restrict the sizing and temperature ratings of connected conductors.

Section 110.14(C)(1) states that where conductors are terminated in equipment, the selected conductor ampacities must be based on Table 310.15(B)(16) unless the equipment is specifically listed and marked otherwise. The intent of this requirement is to clarify which ampacities are used to determine the proper conductor size at equipment terminations.

When equipment of 600 volts or less is evaluated relative to the appropriate temperature characteristics of the terminations, conductors sized according to Table 310.15(B)(16) are required to be used. *UL Guide Information for Electrical Equipment — The White Book* clearly indicates that the 60°C and 75°C provisions for equipment have been determined using conductors from Table 310.15(B)(16). However, installers or designers unaware of the UL guide card information might attempt to select conductors based on a table other than Table 310.15(B)(16), especially if a wiring method that allows the use of ampacities such as those in Table 310.15(B)(17) is used. That use can result in overheated terminations at the equipment. Clearly, the ampacities shown in other tables [such as Table 310.15(B)(17)] could be used for various conditions to which the wiring method is subject (ambient, ampacity correction, etc.), but the conductor size at the termination must be based on ampacities from Table 310.15(B)(16).

Section 110.14(C)(1)(a) requires that conductor termi-

nations, as well as conductors, be rated for the operating temperature of the circuit.

#### Application Example

The load on an 8 AWG THHN, 90°C copper wire is limited to 40 amperes where connected to a disconnect switch with terminals rated at 60°C. The same 8 AWG THHN, 90°C wire is limited to 50 amperes where connected to a fusible switch with terminals rated at 75°C. The conductor ampacities were selected from Table 310.15(B)(16). Not only does termination temperature rating apply to conductor terminations of breakers and fusible switches, but the equipment enclosure marking must also permit terminations above 60°C. Exhibit 110.6 shows an example of termination temperature markings.

### 110.15 High-Leg Marking

On a 4-wire, delta-connected system where the midpoint of one phase winding is grounded, only the conductor or busbar having the higher phase voltage to ground shall be durably and permanently marked by an outer finish that is orange in color or by other effective means. Such identification shall be placed at each point on the system where a connection is made if the grounded conductor is also present.

The high leg is common on a 240/120-volt 3-phase, 4-wire delta system. It is typically designated as “B phase.” The high-leg marking, which is required to be the color orange or other similar effective means, is intended to prevent problems due to the lack of complete standardization where metered and nonmetered equipment are installed in the same installation. Electricians should always test each phase relative to ground with suitable equipment to determine exactly where the high leg is located in the system.

**EXHIBIT 110.6** An example of termination temperature markings on a main circuit breaker. (Courtesy of International Association of Electrical Inspectors)

### 110.16 Arc-Flash Hazard Warning

Electrical equipment, such as switchboards, panelboards, industrial control panels, meter socket enclosures, and motor control centers, that are in other than dwelling units, and are likely to require examination, adjustment, servicing, or maintenance while energized shall be field marked to warn qualified persons of potential electric arc flash hazards. The marking shall be located so as to be clearly visible to qualified persons before examination, adjustment, servicing, or maintenance of the equipment.

This section requires switchboards, panelboards, motor control centers, and other equipment to be individually field marked with proper warning labels to raise the level of awareness of electrical arc flash hazards and thereby decrease the number of accidents that result when electricians do not wear the proper type of protective clothing when working on “hot” (energized) equipment. Exhibit 110.7 displays one example of an equipment warning sign, as required by this section.

**EXHIBIT 110.7** One example of an arc flash warning sign required by 110.16. (Courtesy of the International Association of Electrical Inspectors)

Exhibit 110.8 shows an electrical employee working inside the flash protection boundary in front of a panelboard that has not been de-energized. The worker is wearing personal protective equipment (PPE) considered appropriate flash protection clothing for the flash hazard involved. Suitable PPE appropriate to a particular hazard is described in *NFPA 70E®*, *Standard for Electrical Safety in the Workplace®*.

Accident reports continue to confirm the fact that workers responsible for the installation or maintenance of electri-

**EXHIBIT 110.8** Electrical worker clothed in personal protective equipment (PPE) appropriate for the hazard involved.

cal equipment often do not turn off the power source before working on the equipment. Working on electrical equipment that is energized is a major safety concern in the electrical industry. The main purpose of this requirement is to alert electrical contractors, electricians, facility owners and managers, and other interested parties to some of the hazards when personnel are exposed to energized electrical conductors or circuit parts and to emphasize the importance of turning off the power before working on electrical circuits. This section was revised for the 2011 *Code* to clarify that the requirement does not apply to equipment in “dwelling units.” However, dwelling occupancies include multifamily dwellings, which include multiple dwelling units. A large multifamily dwelling could have the same electric service as a commercial office building. The intent is to provide warnings to electricians working on these larger services.

Informational notes are not mandatory. Employers can be assured that they are providing a safe workplace for their employees if safety-related work practices required by *NFPA 70E* have been implemented and are being followed. (See also the commentary following the definition of *qualified person* in Article 100.)

In addition to the standards referenced in the informational notes and their individual bibliographies, additional information on this subject can be found in the 1997 report “Hazards of Working Electrical Equipment Hot,” published by the National Electrical Manufacturers Association.

Informational Note No. 1: NFPA 70E-2009, *Standard for Electrical Safety in the Workplace*, provides assistance in determining severity of potential exposure, planning safe work practices, and selecting personal protective equipment.

Informational Note No. 2: ANSI Z535.4-1998, *Product Safety Signs and Labels*, provides guidelines for the design of safety signs and labels for application to products.

### 110.18 Arcing Parts

Parts of electrical equipment that in ordinary operation produce arcs, sparks, flames, or molten metal shall be enclosed or separated and isolated from all combustible material.

Examples of electrical equipment that may produce sparks during ordinary operation include open motors having a centrifugal starting switch, open motors with commutators, and collector rings. Adequate separation from combustible material is essential if open motors with those features are used.

Informational Note: For hazardous (classified) locations, see Articles 500 through 517. For motors, see 430.14.

### 110.19 Light and Power from Railway Conductors

Circuits for lighting and power shall not be connected to any system that contains trolley wires with a ground return.

*Exception: Such circuit connections shall be permitted in car houses, power houses, or passenger and freight stations operated in connection with electric railways.*

### 110.21 Marking

The manufacturer’s name, trademark, or other descriptive marking by which the organization responsible for the product can be identified shall be placed on all electrical equipment. Other markings that indicate voltage, current, wattage, or other ratings shall be provided as specified elsewhere in this *Code*. The marking shall be of sufficient durability to withstand the environment involved.

The *Code* requires that equipment ratings be marked on the equipment and that such markings be located so as to be visible or easily accessible during or after installation. See Exhibit 110.9.

EXHIBIT 110.9 Short-circuit current rating marking.

### 110.22 Identification of Disconnecting Means

(A) **General.** Each disconnecting means shall be legibly marked to indicate its purpose unless located and arranged so the purpose is evident. The marking shall be of sufficient durability to withstand the environment involved.

This section requires that markings specifically identify the purpose of each piece of equipment — that is, the marking should not simply indicate “motor” but rather “motor, water pump” or not simply “lights” but rather “lights, front lobby.” Consideration of the form of identification is also required to assure that the markings do not fade or wear off. Section 408.4 and its associated commentary provide additional requirements and information on circuit directories for switchboards and panelboards.

(B) **Engineered Series Combination Systems.** Equipment enclosures for circuit breakers or fuses applied in compliance with series combination ratings selected under engineering supervision in accordance with 240.86(A) shall be legibly marked in the field as directed by the engineer to indicate the equipment has been applied with a series combination rating. The marking shall be readily visible and state the following:

CAUTION — ENGINEERED SERIES  
COMBINATION SYSTEM RATED \_\_\_\_\_  
AMPERES. IDENTIFIED REPLACEMENT  
COMPONENTS REQUIRED.

Section 110.22(B) requires the enclosures of engineered series-rated overcurrent devices to be legibly marked. If the ratings are determined under engineering supervision, the equipment must have a label, as specified in 110.22(B), to indicate that the series combination rating has been used. It is important that the warnings on replacement components be heeded in order to maintain the level of protection provided by the design.

**(C) Tested Series Combination Systems.** Equipment enclosures for circuit breakers or fuses applied in compliance with the series combination ratings marked on the equipment by the manufacturer in accordance with 240.86(B) shall be legibly marked in the field to indicate the equipment has been applied with a series combination rating. The marking shall be readily visible and state the following:

CAUTION — SERIES COMBINATION SYSTEM  
RATED \_\_\_\_ AMPERES. IDENTIFIED  
REPLACEMENT COMPONENTS REQUIRED.

Section 110.22(C) requires the enclosures of tested series combination systems to be legibly marked. The equipment manufacturer can mark the equipment to be used with series combination ratings. If the equipment is installed in the field at its marked series combination rating, the equipment must have an additional label, as specified in 110.22, to indicate that the series combination rating has been used.

### 110.23 Current Transformers

Unused current transformers associated with potentially energized circuits shall be short-circuited.

Because Article 450 specifically exempts current transformers, the requirement in 110.23 provides the practical solution to preventing damage to current transformers not connected to a load or for unused current transformers.

### 110.24 Available Fault Current

**(A) Field Marking.** Service equipment in other than dwelling units shall be legibly marked in the field with the maximum available fault current. The field marking(s) shall include the date the fault current calculation was performed and be of sufficient durability to withstand the environment involved.

**(B) Modifications.** When modifications to the electrical installation occur that affect the maximum available fault

current at the service, the maximum available fault current shall be verified or recalculated as necessary to ensure the service equipment ratings are sufficient for the maximum available fault current at the line terminals of the equipment. The required field marking(s) in 110.24(A) shall be adjusted to reflect the new level of maximum available fault current.

*Exception: The field marking requirements in 110.24(A) and 110.24(B) shall not be required in industrial installations where conditions of maintenance and supervision ensure that only qualified persons service the equipment.*

Equipment must have an interrupting rating or short-circuit current rating equal to or greater than the available fault current if it is to be used safely. Any equipment operating with ratings less than the available fault current is potentially unsafe. Existing electrical distribution systems often experience change over the life of the system. As the system ages, the supply network to which it is connected is impacted by growth and is forced to increase capacity or increase efficiency by reducing transformer impedance. In some cases, alternative energy systems can be added to existing installations. Such changes to the electrical distribution system can result in an increase of the available fault current. This increase in available fault can exceed the ratings of the originally installed equipment violating 110.9 and 110.10 and creating an unsafe condition for personnel. Section 110.24 was added to the 2011 *Code* to provide a requirement for initial marking of maximum available fault current as well as the requirement to update the information when the system is modified.

In order to complete an arc-flash hazard analysis per Section 130.3 of *NFPA 70E, Standard for Electrical Safety in the Workplace*, the available fault current must be known. This analysis is used to determine the arc-flash protection boundary and required PPE in accordance with *NFPA 70E*, Section 130.3(A) and 130.3(B). The equipment must be then be marked with the incident energy or required level of PPE per 130.3(C). In addition, per 130.3, an arc-flash hazard analysis is also required to be updated when major modifications or renovations take place. The analysis must be reviewed periodically and not exceed a 5-year timeline to account for changes in the electrical distribution system that could affect the original arc-flash analysis.

## II. 600 Volts, Nominal, or Less

### 110.26 Spaces About Electrical Equipment

Access and working space shall be provided and maintained about all electrical equipment to permit ready and safe operation and maintenance of such equipment.

Key to understanding 110.26 is the division of requirements for spaces about electrical equipment in two separate and distinct categories: working space and dedicated equipment space. The term *working space* generally applies to the protection of the worker, and *dedicated equipment space* applies to the space reserved for future access to electrical equipment and to protection of the equipment from intrusion by nonelectrical equipment. The performance requirements for all spaces about electrical equipment are set forth in this section. Storage of material that blocks access or prevents safe work practices must be avoided at all times.

**(A) Working Space.** Working space for equipment operating at 600 volts, nominal, or less to ground and likely to require examination, adjustment, servicing, or maintenance while energized shall comply with the dimensions of 110.26(A)(1), (A)(2), and (A)(3) or as required or permitted elsewhere in this *Code*.

The intent of 110.26(A) is to provide enough space for personnel to perform any of the operations listed without jeopardizing worker safety. Examples of such equipment include panelboards, switches, circuit breakers, controllers, and controls on heating and air-conditioning equipment. It is important to understand that the word *examination*, as used in 110.26(A), includes such tasks as checking for the presence of voltage using a portable voltmeter.

Minimum working clearances are not required if the equipment is such that it is not likely to require examination, adjustment, servicing, or maintenance while energized. However, access and working space are still required by the opening paragraph of 110.26.

This section specifies the required working space for such equipment as panelboards, switches, circuit breakers, controllers, and controls on heating and air-conditioning equipment. The intent is to provide enough space for personnel to perform any of the operations listed without jeopardizing worker safety. The word *examination*, as used in 110.26(A), includes such tasks as checking for the presence of voltage using a portable voltmeter.

Minimum working clearances are not required if the equipment is such that it is not likely to require examination, adjustment, servicing, or maintenance while energized. However, access and working space are still required by the opening paragraph of 110.26.

**(1) Depth of Working Space.** The depth of the working space in the direction of live parts shall not be less than that specified in Table 110.26(A)(1) unless the requirements of 110.26(A)(1)(a), (A)(1)(b), or (A)(1)(c) are met. Distances shall be measured from the exposed live parts or from the enclosure or opening if the live parts are enclosed.

**TABLE 110.26(A)(1) Working Spaces**

Nominal Voltage to Ground	Minimum Clear Distance		
	Condition 1	Condition 2	Condition 3
0–150	914 mm (3 ft)	914 mm (3 ft)	914 mm (3 ft)
151–600	914 mm (3 ft)	1.07 m (3 ft 6 in.)	1.22 m (4 ft)

Note: Where the conditions are as follows:

**Condition 1** — Exposed live parts on one side of the working space and no live or grounded parts on the other side of the working space, or exposed live parts on both sides of the working space that are effectively guarded by insulating materials.

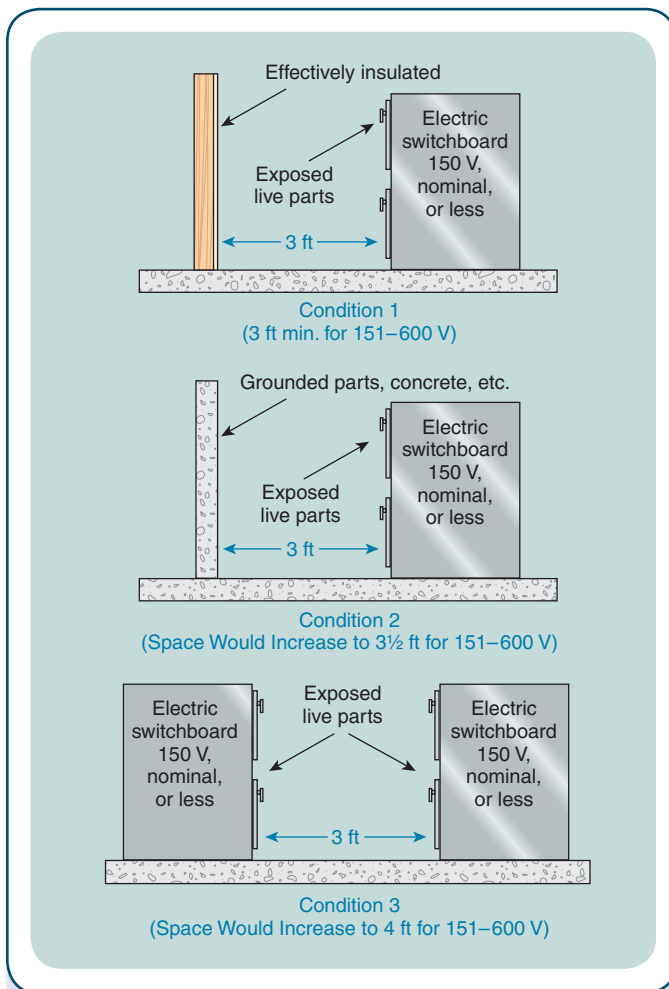

**Condition 2** — Exposed live parts on one side of the working space and grounded parts on the other side of the working space. Concrete, brick, or tile walls shall be considered as grounded.

**Condition 3** — Exposed live parts on both sides of the working space.

Included in the clearance requirements in Table 110.26(A)(1) is the step-back distance from the face of the equipment. It provides requirements for clearances away from the equipment, based on the circuit voltage to ground and whether there are grounded or ungrounded objects in the step-back space or exposed live parts across from each other. The voltages to ground consist of two groups: 0 to 150, inclusive, and 151 to 600, inclusive.

Examples of common electrical supply systems covered in the 0 to 150 volts to ground group are 120/240-volt, single-phase, 3-wire and 208Y/120-volt, 3-phase, 4-wire systems. Examples of common electrical supply systems covered in the 151 to 600 volts to ground group are 240-volt, 3-phase, 3-wire; 480Y/277-volt, 3-phase, 4-wire; and 480-volt, 3-phase, 3-wire (ungrounded and corner grounded) systems. Remember, where an ungrounded system is utilized, the voltage to ground (by definition) is the greatest voltage between the given conductor and any other conductor of the circuit. For example, the voltage to ground for a 480-volt ungrounded delta system is 480 volts. See Exhibit 110.10 for the general working clearance requirements for each of the three conditions listed in Table 110.26(A)(1). For assemblies, such as switchboards or motor-control centers, that are accessible from the back and expose live parts, the working clearance dimensions are required at the rear of the equipment, as illustrated. Note that for Condition 3, where there is an enclosure on opposite sides of the working space, the clearance for only one working space is required.

(a) *Dead-Front Assemblies.* Working space shall not be required in the back or sides of assemblies, such as dead-front switchboards or motor control centers, where all connections and all renewable or adjustable parts, such as fuses or switches, are accessible from locations other than the back or sides. Where rear access is required to work on non-electrical parts on the back of enclosed equipment, a mini-

**EXHIBIT 110.10** Distances measured from the live parts if the live parts are exposed or from the enclosure front if the live parts are enclosed.

imum horizontal working space of 762 mm (30 in.) shall be provided.

The intent of this section is to point out that work space is required only from the side(s) of the enclosure requiring access. The general rule applies: Equipment that requires front, rear, or side access for the electrical activities described in 110.26(A) must meet the requirements of Table 110.26(A) (1). In many cases, equipment of “dead-front” assemblies requires only front access. For equipment that requires rear access for nonelectrical activity, however, a reduced working space of at least 30 in. must be provided. Exhibit 110.11 shows a reduced working space of 30 in. at the rear of equipment to allow work on nonelectrical parts.

(b) *Low Voltage.* By special permission, smaller working spaces shall be permitted where all exposed live parts

**EXHIBIT 110.11** Example of the 30-in. minimum working space at the rear of equipment to allow work on nonelectrical parts, such as the replacement of an air filter.

operate at not greater than 30 volts rms, 42 volts peak, or 60 volts dc.

(c) *Existing Buildings.* In existing buildings where electrical equipment is being replaced, Condition 2 working clearance shall be permitted between dead-front switchboards, panelboards, or motor control centers located across the aisle from each other where conditions of maintenance and supervision ensure that written procedures have been adopted to prohibit equipment on both sides of the aisle from being open at the same time and qualified persons who are authorized will service the installation.

This section permits some relief for installations that are being upgraded. When assemblies such as dead-front switchboards, panelboards, or motor-control centers are replaced in an existing building, the working clearance allowed is that required by Table 110.26(A)(1), Condition 2. The reduction from a Condition 3 to a Condition 2 clearance is allowed only where a written procedure prohibits facing doors of equipment from being open at the same time and where only authorized and qualified persons service the installation. Exhibit 110.12 illustrates this relief for existing buildings.

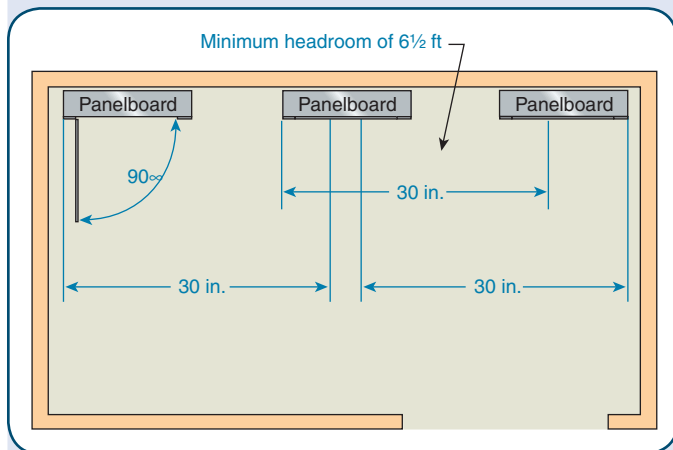

(2) **Width of Working Space.** The width of the working space in front of the electrical equipment shall be the width of the equipment or 762 mm (30 in.), whichever is greater. In all cases, the work space shall permit at least a 90 degree opening of equipment doors or hinged panels.

Regardless of the width of the electrical equipment, the working space cannot be less than 30 in. wide, as required

**EXHIBIT 110.12** Permitted reduction from a Condition 3 to a Condition 2 clearance according to 110.26(A)(1)(c).

by Table 110.26(A)(1). This space allows an individual to have at least shoulder-width space in front of the equipment. The 30-in. measurement can be made from either the left or the right edge of the equipment and can overlap other electrical equipment, provided the other equipment does not extend beyond the clearance required by Table 110.26(A)(1). If the equipment is wider than 30 in., the left-to-right space must be equal to the width of the equipment. Exhibit 110.13 illustrates the 30-in. width requirement.

**EXHIBIT 110.13** The 30-in. wide front working space, which is not required to be directly centered on the electrical equipment if space is sufficient for safe operation and maintenance of such equipment. The working space can overlap other electrical equipment.

Sufficient depth in the working space is also required to allow a panel or a door to open at least 90 degrees. If doors or hinged panels are wider than 3 ft, more than a 3-ft deep

working space must be provided to allow a full 90 degree opening. (See Exhibit 110.14.)

**EXHIBIT 110.14** Illustration of requirement that the depth of working space must be sufficient to allow a full 90 degree opening of equipment doors in order to ensure a safe working approach.

**(3) Height of Working Space.** The work space shall be clear and extend from the grade, floor, or platform to a height of 2.0 m (6½ ft) or the height of the equipment, whichever is greater. Within the height requirements of this section, other equipment that is associated with the electrical installation and is located above or below the electrical equipment shall be permitted to extend not more than 150 mm (6 in.) beyond the front of the electrical equipment.

In addition to requiring a working space to be clear from the floor to a height of 6½ ft or to the height of the equipment, whichever is greater, 110.26(A)(3) permits electrical equipment located above or below other electrical equipment to extend into the working space not more than 6 in. This requirement allows the placement of a 12 in. × 12 in. wireway on the wall directly above or below a 6 in.-deep panelboard without impinging on the working space or compromising practical working clearances. The requirement prohibits large differences in depth of equipment below or above other equipment that specifically requires working space. To minimize the amount of space required for electrical equipment, large free-standing, dry-type transformers are commonly installed within the required work space for a wall-mounted panelboard, which compromises clear access to the panelboard and

which is clearly not permitted by this section. Electrical equipment that produces heat or that otherwise requires ventilation also must comply with 110.3(B) and 110.13.

*Exception No. 1: In existing dwelling units, service equipment or panelboards that do not exceed 200 amperes shall be permitted in spaces where the height of the working space is less than 2.0 m (6½ ft).*

*Exception No. 2: Meters that are installed in meter sockets shall be permitted to extend beyond the other equipment. The meter socket shall be required to follow the rules of this section.*

This exception is new in the 2011 *Code*. It recognizes that a meter socket installation could be in compliance with this section, but the installation of the meter into the socket could extend beyond the 6 in. permitted by 110.26(a)(3). The exception permits the meter to extend further, provided the meter socket does not exceed the 6 in. depth.

**(B) Clear Spaces.** Working space required by this section shall not be used for storage. When normally enclosed live parts are exposed for inspection or servicing, the working space, if in a passageway or general open space, shall be suitably guarded.

Section 110.26(B), as well as the rest of 110.26, does not prohibit the placement of panelboards in corridors or passageways. For that reason, when the covers of corridor-mounted panelboards are removed for servicing or other work, access to the area around the panelboard should be guarded or limited to prevent injury to unqualified persons using the corridor.

Equipment that requires servicing while energized must be located in an area that is not used for storage, as shown in Exhibit 110.15.

### **(C) Entrance to and Egress from Working Space.**

**(1) Minimum Required.** At least one entrance of sufficient area shall be provided to give access to and egress from working space about electrical equipment.

The requirements in this section are intended to provide access to electrical equipment. However, the primary intent is to provide egress from the area so that workers can escape if there is an arc-flash incident.

**(2) Large Equipment.** For equipment rated 1200 amperes or more and over 1.8 m (6 ft) wide that contains overcurrent

**EXHIBIT 110.15** Equipment location that is free of storage to allow the equipment to be worked on safely. (Courtesy of the International Association of Electrical Inspectors)

devices, switching devices, or control devices, there shall be one entrance to and egress from the required working space not less than 610 mm (24 in.) wide and 2.0 m (6½ ft) high at each end of the working space.

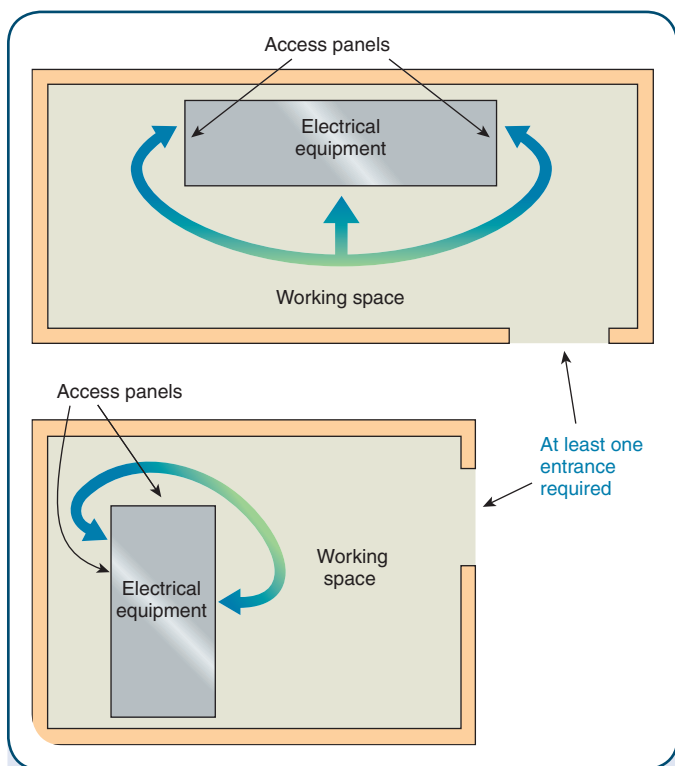

A single entrance to and egress from the required working space shall be permitted where either of the conditions in 110.26(C)(2)(a) or (C)(2)(b) is met.

Where the entrance(s) to the working space is through a door, each door must comply with the requirements for swinging open in the direction of egress and have door opening hardware that does not require turning of a door knob or similar action that may preclude quick exit from the area in the event of an emergency. This requirement affords safety for workers exposed to energized conductors by allowing an injured worker to safely and quickly exit an electrical room without having to turn knobs or pull doors open.

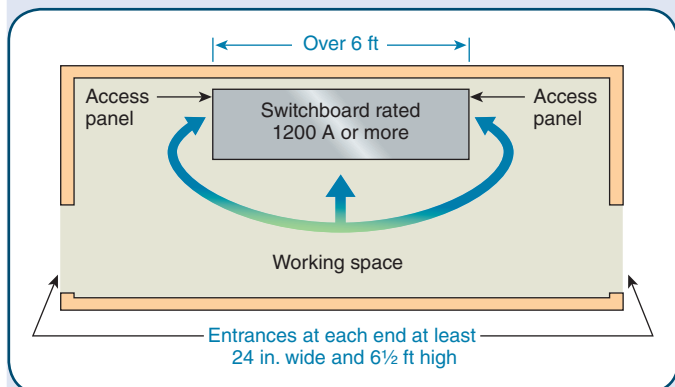

Exhibits 110.16 and 110.17 provide a graphical explanation of access and entrance requirements for working spaces. Exhibit 110.18 shows an unacceptable and hazardous work space arrangement.

(a) *Unobstructed Egress.* Where the location permits a continuous and unobstructed way of egress travel, a single entrance to the working space shall be permitted.

(b) *Extra Working Space.* Where the depth of the working space is twice that required by 110.26(A)(1), a single entrance shall be permitted. It shall be located such that the distance from the equipment to the nearest edge of the entrance is not less than the minimum clear distance specified in Table 110.26(A)(1) for equipment operating at that voltage and in that condition.

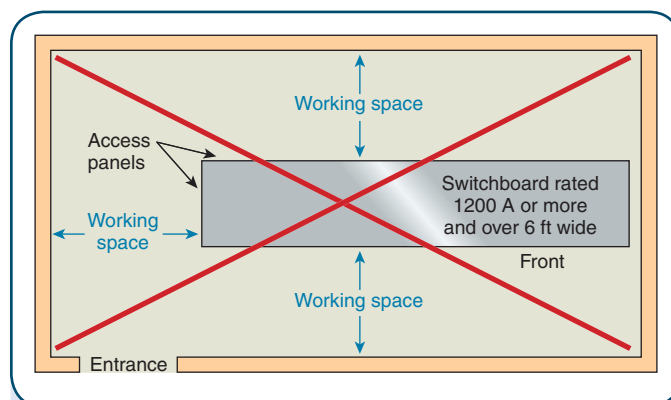

**EXHIBIT 110.16** Basic Rule, 110.26(C)(1). At least one entrance is required to provide access to the working space around electrical equipment. The lower installation would not be acceptable for a switchboard over 6 ft wide and rated 1200 amperes or more.

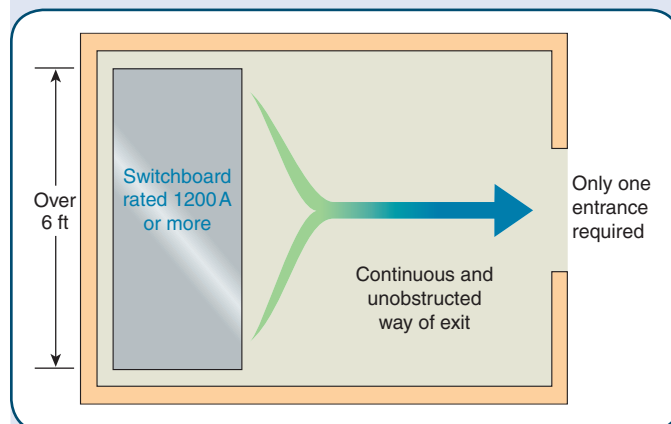

**EXHIBIT 110.17** Basic Rule, 110.26(C)(2). For equipment rated 1200 amperes or more and over 6 ft wide, one entrance not less than 24 in. wide and 6½ ft high is required at each end.

For an explanation of paragraphs 110.26(C)(2)(a) and 110.26(C)(2)(b), see Exhibits 110.19 and 110.20.

**(3) Personnel Doors.** Where equipment rated 1200 A or more that contains overcurrent devices, switching devices, or control devices is installed and there is a personnel

**EXHIBIT 110.18** Unacceptable arrangement of a large switchboard. A worker could be trapped behind arcing electrical equipment.

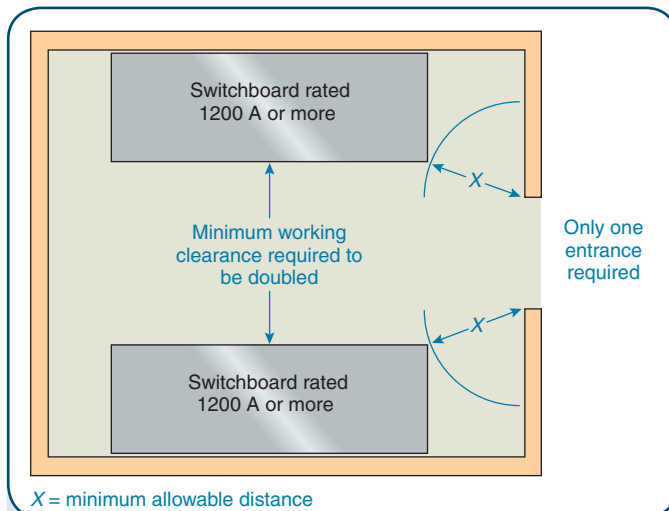

**EXHIBIT 110.19** Equipment location that allows a continuous and unobstructed way of exit travel.

door(s) intended for entrance to and egress from the working space less than 7.6 m (25 ft) from the nearest edge of the working space, the door(s) shall open in the direction of egress and be equipped with panic bars, pressure plates, or other devices that are normally latched but open under simple pressure.

The requirements in this section are based on equipment rated 1200 A or more, not on the width of the equipment. The measurement for less than 25 ft for the personnel door(s) is made from the nearest edge of the working space, and the requirement for panic hardware and outward egress is independent of the need for two exits from the working space. Not every electrical installation is in an equipment room. This section requires personnel doors that are up to 25 ft from the working space to have panic hardware and to open in the direction of egress from the area. Exhibit 110.21 shows one of the required exits.

**EXHIBIT 110.20** Working space with one entrance. Only one entrance is required if the working space required by 110.26(A) is doubled. See Table 110.26(A)(1) for permitted dimensions of X.

**EXHIBIT 110.21** An installation of large equipment showing one of the required exits. (Courtesy of the International Association of Electrical Inspectors)

**(D) Illumination.** Illumination shall be provided for all working spaces about service equipment, switchboards, panelboards, or motor control centers installed indoors and shall not be controlled by automatic means only. Additional lighting outlets shall not be required where the work space is illuminated by an adjacent light source or as permitted by 210.70(A)(1), Exception No. 1, for switched receptacles.

This section was revised for the 2011 *Code*. It now requires working spaces around service equipment, switchboards, and motor control centers to have a nonautomatic means to control the lighting. Automatic lighting control through de-

vices such as occupancy sensors and similar devices would not be prohibited. However, a manual means to bypass the automatic control would be required.

**(E) Dedicated Equipment Space.** All switchboards, panelboards, and motor control centers shall be located in dedicated spaces and protected from damage.

*Exception: Control equipment that by its very nature or because of other rules of the Code must be adjacent to or within sight of its operating machinery shall be permitted in those locations.*

**(1) Indoor.** Indoor installations shall comply with 110.26(E)(1)(a) through (E)(1)(d).

(a) *Dedicated Electrical Space.* The space equal to the width and depth of the equipment and extending from the floor to a height of 1.8 m (6 ft) above the equipment or to the structural ceiling, whichever is lower, shall be dedicated to the electrical installation. No piping, ducts, leak protection apparatus, or other equipment foreign to the electrical installation shall be located in this zone.

*Exception: Suspended ceilings with removable panels shall be permitted within the 1.8-m (6-ft) zone.*

(b) *Foreign Systems.* The area above the dedicated space required by 110.26(E)(1)(a) shall be permitted to contain foreign systems, provided protection is installed to avoid damage to the electrical equipment from condensation, leaks, or breaks in such foreign systems.

(c) *Sprinkler Protection.* Sprinkler protection shall be permitted for the dedicated space where the piping complies with this section.

(d) *Suspended Ceilings.* A dropped, suspended, or similar ceiling that does not add strength to the building structure shall not be considered a structural ceiling.

The dedicated electrical space, which extends the footprint of the switchboard or panelboard from the floor to a height of 6 ft above the height of the equipment or to the structural ceiling (whichever is lower), is required to be clear of piping, ducts, leak protection apparatus, or equipment foreign to the electrical installation. Plumbing, heating, ventilation, and air-conditioning piping, ducts, and equipment must be installed outside the width and depth zone. Busways, conduits, raceways, and cables are permitted to enter equipment through this zone.

Foreign systems installed directly above the dedicated space reserved for electrical equipment are required to

include protective equipment that ensures that occurrences such as leaks, condensation, and even breaks do not damage the electrical equipment located below.

Sprinkler protection is permitted for the dedicated spaces as long as the sprinkler or other suppression system piping complies with 110.26(E)(1)(c). A dropped, suspended, or similar ceiling is permitted to be located directly in the dedicated space, as are they are not considered structural ceilings. Building structural members are also permitted in this space.

The electrical equipment also must be protected from physical damage. Damage can be caused by activities performed near the equipment, such as material handling by personnel or the operation of a forklift or other mobile equipment. See 110.27(B) for other requirements relating to the protection of electrical equipment.

Exhibits 110.22, 110.23, and 110.24 illustrate the two distinct indoor installation spaces required by 110.26(A) and 110.26(E), that is, the working space and the dedicated electrical space.

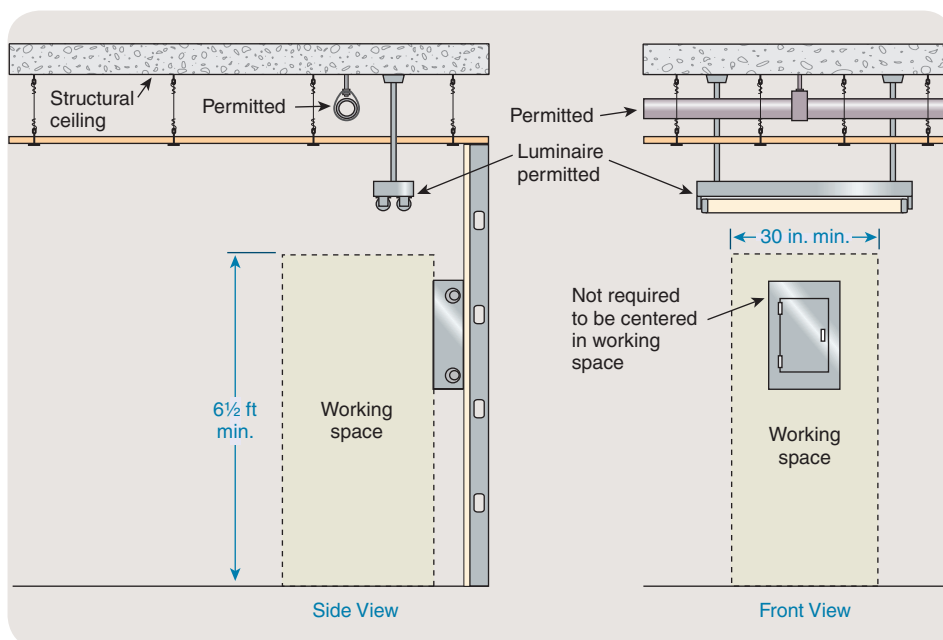

In Exhibit 110.22, the dedicated electrical space required by 110.26(E) is the space outlined by the width and the depth of the equipment (the footprint) and extending from the floor to 6 ft above the equipment or to the structural ceiling (whichever is lower). The dedicated electrical space is reserved for the installation of electrical equipment and for the installation of conduits, cable trays, and so on, entering or exiting that equipment. The outlined area in front of

**EXHIBIT 110.22** The two distinct indoor installation spaces required by 110.26(A) and 110.26(E): the working space and the dedicated electrical space.

the electrical equipment in Exhibit 110.22 is the working space required by 110.26(A). Note that sprinkler protection is afforded the entire dedicated electrical space and working

**EXHIBIT 110.23** The working space required by 110.26(A) in front of a panelboard. This illustration supplements the dedicated electrical space shown in Exhibit 110.22.

**EXHIBIT 110.24** The dedicated electrical space required by 110.26(E)(1) above and below a panelboard.

space without actually entering either space. Also note that the exhaust duct is not located in or directly above the dedicated electrical space. Although not specifically required to be located here, this duct location may be a cost-effective solution that avoids the substantial physical protection requirements of 110.26(E)(1)(b).

Exhibit 110.23 illustrates the working space required in front of the panelboard by 110.26(A). No equipment, electrical or otherwise, is allowed in the working space. Exhibit 110.24 illustrates the dedicated electrical space above and below the panelboard required by 110.26(E)(1). This space is for the cables, raceways, and so on, that run to and from the panelboard.

**(2) Outdoor.** Outdoor electrical equipment shall be installed in suitable enclosures and shall be protected from accidental contact by unauthorized personnel, or by vehicular traffic, or by accidental spillage or leakage from piping systems. The working clearance space shall include the zone described in 110.26(A). No architectural appurtenance or other equipment shall be located in this zone.

Extreme care should be taken where protection from unauthorized personnel or vehicular traffic is added to existing installations in order to comply with 110.26(E)(2). Any excavation or driving of steel into the ground for the placement of fencing, vehicle stops, or bollards should be done only after a thorough investigation of the below-grade wiring.

#### **(F) Locked Electrical Equipment Rooms or Enclosures.**

Electrical equipment rooms or enclosures housing electrical apparatus that are controlled by a lock(s) shall be considered accessible to qualified persons.

This requirement allows equipment enclosures and rooms to be locked to prevent unauthorized access. Such rooms or enclosures are nonetheless considered accessible if qualified personnel have access.

### **110.27 Guarding of Live Parts**

#### **(A) Live Parts Guarded Against Accidental Contact.**

Except as elsewhere required or permitted by this *Code*, live parts of electrical equipment operating at 50 volts or more shall be guarded against accidental contact by approved enclosures or by any of the following means:

- (1) By location in a room, vault, or similar enclosure that is accessible only to qualified persons.
- (2) By suitable permanent, substantial partitions or screens arranged so that only qualified persons have access to the space within reach of the live parts. Any openings in such partitions or screens shall be sized and located so that persons are not likely to come into accidental contact with the live parts or to bring conducting objects into contact with them.
- (3) By location on a suitable balcony, gallery, or platform elevated and arranged so as to exclude unqualified persons.

(4) By elevation of 2.5 m (8 ft) or more above the floor or other working surface.

Live parts of electrical equipment should be covered, shielded, enclosed, or otherwise protected by covers, barriers, mats, or platforms to prevent the likelihood of contact by persons or objects. See the definitions of *dead front* and *isolated (as applied to location)* in Article 100.

Contact conductors used for traveling cranes are permitted to be bare by 610.13(B) and 610.21(A). Although contact conductors obviously have to be bare for contact shoes on the moving member to make contact with the conductor, it is possible to place guards near the conductor to prevent its accidental contact with persons and still have slots or spaces through which the moving contacts can operate. The *Code* also recognizes the guarding of live parts by elevation.

**(B) Prevent Physical Damage.** In locations where electrical equipment is likely to be exposed to physical damage, enclosures or guards shall be so arranged and of such strength as to prevent such damage.

**(C) Warning Signs.** Entrances to rooms and other guarded locations that contain exposed live parts shall be marked

with conspicuous warning signs forbidding unqualified persons to enter.

Informational Note: For motors, see 430.232 and 430.233. For over 600 volts, see 110.34.

110.28 Enclosure Types

Enclosures (other than surrounding fences or walls) of switchboards, panelboards, industrial control panels, motor control centers, meter sockets, enclosed switches, transfer switches, power outlets, circuit breakers, adjustable-speed drive systems, pullout switches, portable power distribution equipment, termination boxes, general-purpose transformers, fire pump controllers, fire pump motors, and motor controllers, rated not over 600 volts nominal and intended for such locations, shall be marked with an enclosure-type number as shown in Table 110.28.

This information applies to electrical equipment enclosures. This material was relocated for the 2011 *Code* to make it clear that it only applies to equipment rated 600 volts and less. The information in Commentary Table 110.1 is taken from the 2010 *UL Guide Information for Electrical Equipment — The White Book*, category AALZ, “Electrical Equip-

COMMENTARY TABLE 110.1 Environmental Protections for Nonhazardous Locations, by Type of Enclosure

Enclosure Type Number	Provides a Degree of Protection Against the Following Environmental Conditions*
1	Indoor use
2	Indoor use, limited amounts of falling water
3R	Outdoor use, undamaged by the formation of ice on the enclosure <sup>†</sup>
3	Same as 3R plus windblown dust
3S	Same as 3R plus windblown dust; external mechanisms remain operable while ice laden
4	Outdoor use, splashing water, windblown dust, hose-directed water, undamaged by the formation of ice on the enclosure <sup>†</sup>
4X	Same as 4 plus resists corrosion
5	Indoor use to provide a degree of protection against settling airborne dust, falling dirt, and dripping noncorrosive liquids
6	Same as 3R plus entry of water during temporary submersion at a limited depth
6P	Same as 3R plus entry of water during prolonged submersion at a limited depth
12, 12K	Indoor use, dust, dripping noncorrosive liquids
13	Indoor use, dust, spraying water, oil, and noncorrosive coolants

\*All enclosure types provide a degree of protection against ordinary corrosion and against accidental contact with the enclosed equipment when doors or covers are closed and in place. All types of enclosures provide protection against a limited amount of falling dirt.

<sup>†</sup>All outdoor-type enclosures provide a degree of protection against rain, snow, and sleet. Outdoor enclosures are also suitable for use indoors if they meet the environmental conditions present.

Source: Underwriters Laboratories, *General Information Directory*, 2010 edition.

\*Mechanism shall be operable when ice covered.

Informational Note No. 1: The term *raintight* is typically used in conjunction with Enclosure Types 3, 3S, 3SX, 3X, 4, 4X, 6, and 6P. The term *rainproof* is typically used in conjunction with Enclosure Types 3R, and 3RX. The term *watertight* is typically used in conjunction with Enclosure Types 4, 4X, 6, 6P. The term *driptight* is typically used in conjunction with Enclosure Types 2, 5, 12, 12K, and 13. The term *dusttight* is typically used in conjunction with Enclosure Types 3, 3S, 3SX, 3X, 5, 12, 12K, and 13.

Informational Note No. 2: Ingress protection (IP) ratings may be found in ANSI/NEMA 60529, *Degrees of Protection Provided by Enclosures*. IP ratings are not a substitute for Enclosure Type ratings.

A new informational note was added to Table 110.28 that references IEC ingress protection ratings, which may be indicated on some enclosures. These ratings are not a substitute for the type ratings in the table.

ment for Use in Ordinary Locations.” The table summarizes the intended uses of the various types of enclosures for non-hazardous locations.

Enclosures that comply with the requirements for more than one type of enclosure may be marked with multiple

designations. Enclosures marked with a type may also be marked as follows:

A Type 1 may be marked “Indoor Use Only.”

A Type 3, 3S, 4, 4X, 6, or 6P may be marked “Raintight.”

A Type 3R may be marked “Rainproof.”

A Type 4, 4X, 6, or 6P may be marked “Watertight.”

A Type 4X or 6P may be marked “Corrosion Resistant.”

A Type 2, 5, 12, 12K, or 13 may be marked “Driptight.”

A Type 3, 3S, 5, 12K, or 13 may be marked “Dusttight.”

For equipment designated “Raintight,” testing designed to simulate exposure to a beating rain will not result in entrance of water. For equipment designated “Rainproof,” testing designed to simulate exposure to a beating rain will not interfere with the operation of the apparatus or result in wetting of live parts and wiring within the enclosure. “Watertight” equipment is so constructed that water does not enter the enclosure when subjected to a stream of water. “Corrosion resistant” equipment is constructed so that it provides a degree of protection against exposure to corrosive agents such as salt spray. “Driptight” equipment is constructed so that falling moisture or dirt does not enter the enclosure. “Dusttight” equipment is constructed so that circulating or airborne dust does not enter the enclosure.

Exhibit 110.25 illustrates a label for a transformer. The circled area on the label indicates the enclosure type, which is a Type 3R.

**EXHIBIT 110.25** A typical label for a transformer enclosure, showing an enclosure type rating.

Table 110.28 shall be used for selecting these enclosures for use in specific locations other than hazardous (classified) locations. The enclosures are not intended to protect against conditions such as condensation, icing, corrosion, or contamination that may occur within the enclosure or enter via the conduit or unsealed openings.

### III. Over 600 Volts, Nominal

#### 110.30 General

Conductors and equipment used on circuits over 600 volts, nominal, shall comply with Part I of this article and with 110.30 through 110.40, which supplement or modify Part I. In no case shall the provisions of this part apply to equipment on the supply side of the service point.

The rules for systems less than 600 volts, nominal, do not apply to systems over 600 volts, nominal, in all cases. See “Over 600 volts” in the index to this *Handbook* for articles, parts, and sections that include the specific requirements for installations over 600 volts. Typical equipment covered by Part III of Article 110 is shown in Exhibit 110.26.

Equipment on the supply side of the service point is outside the scope of the *NEC*. Such equipment is covered by ANSI C2, *National Electrical Safety Code*, published by the Institute of Electrical and Electronics Engineers (IEEE).

#### 110.31 Enclosure for Electrical Installations

Electrical installations in a vault, room, or closet or in an area surrounded by a wall, screen, or fence, access to which is controlled by a lock(s) or other approved means, shall be considered to be accessible to qualified persons only. The type of enclosure used in a given case shall be designed and constructed according to the nature and degree of the hazard(s) associated with the installation.

For installations other than equipment as described in 110.31(D), a wall, screen, or fence shall be used to enclose an outdoor electrical installation to deter access by persons who are not qualified. A fence shall not be less than 2.1 m (7 ft) in height or a combination of 1.8 m (6 ft) or more of fence fabric and a 300-mm (1-ft) or more extension utilizing three or more strands of barbed wire or equivalent. The distance from the fence to live parts shall be not less than given in Table 110.31.

Informational Note: See Article 450 for construction requirements for transformer vaults.

**(A) Electrical Vaults.** Where an electrical vault is required or specified for conductors and equipment operating at over 600 volts, nominal, the following shall apply.

**(1) Walls and Roof.** The walls and roof shall be constructed of materials that have adequate structural strength

**EXHIBIT 110.26** Medium voltage metal-clad switchgear covered in Part III of Article 110.

**TABLE 110.31** Minimum Distance from Fence to Live Parts

Nominal Voltage	Minimum Distance to Live Parts	
	m	ft
601–13,799	3.05	10
13,800–230,000	4.57	15
Over 230,000	5.49	18

Note: For clearances of conductors for specific system voltages and typical BIL ratings, see ANSI C2-2007, *National Electrical Safety Code*.

for the conditions, with a minimum fire rating of 3 hours. For the purpose of this section, studs and wallboard construction shall not be permitted.

**(2) Floors.** The floors of vaults in contact with the earth shall be of concrete that is not less than 102 mm (4 in.) thick, but where the vault is constructed with a vacant space or other stories below it, the floor shall have adequate structural strength for the load imposed on it and a minimum fire resistance of 3 hours.

**(3) Doors.** Each doorway leading into a vault from the building interior shall be provided with a tight-fitting door that has a minimum fire rating of 3 hours. The authority having jurisdiction shall be permitted to require such a door for an exterior wall opening where conditions warrant.

Exception to (1), (2), and (3): Where the vault is protected with automatic sprinkler, water spray, carbon dioxide, or halon, construction with a 1-hour rating shall be permitted.

**(4) Locks.** Doors shall be equipped with locks, and doors shall be kept locked, with access allowed only to qualified persons. Personnel doors shall swing out and be equipped with panic bars, pressure plates, or other devices that are normally latched but that open under simple pressure.

**(5) Transformers.** Where a transformer is installed in a vault as required by Article 450, the vault shall be constructed in accordance with the requirements of Part III of Article 450.

Informational Note No. 1: For additional information, see ANSI/ASTM E119-1995, *Method for Fire Tests of Building Construction and Materials*, NFPA 251-2006, *Standard Methods of Tests of Fire Resistance of Building Construction and Materials*, and NFPA 80-2010, *Standard for Fire Doors and Other Opening Protectives*.

Informational Note No. 2: A typical 3-hour construction is 150 mm (6 in.) thick reinforced concrete.

Section 110.31 was revised and expanded for the 2011 Code. Its construction requirements have been expanded beyond fire resistance rating to include more detailed requirements.

These requirements apply in those locations where a vault is required or specified. The requirements for doors and locks are based on the requirement in 450.43. Where a vault is required by Article 450, it must be constructed in accordance with Article 450, Part III. Although the language in 450 is similar to this section, there are requirements for door sills and ventilation that would not be applicable in an equipment/conductor vault. An exception to the vault construction requirements is added to allow for 1 hr construction when the vault is protected by a fire suppression system. This exception is based on 450.42 and 450.43.

## **(B) Indoor Installations.**

**(1) In Places Accessible to Unqualified Persons.** Indoor electrical installations that are accessible to unqualified persons shall be made with metal-enclosed equipment. Metal-enclosed switchgear, unit substations, transformers, pull boxes, connection boxes, and other similar associated equipment shall be marked with appropriate caution signs. Openings in ventilated dry-type transformers or similar openings in other equipment shall be designed so that foreign objects

inserted through these openings are deflected from energized parts.

**(2) In Places Accessible to Qualified Persons Only.** Indoor electrical installations considered accessible only to qualified persons in accordance with this section shall comply with 110.34, 110.36, and 490.24.

**(C) Outdoor Installations.**

**(1) In Places Accessible to Unqualified Persons.** Outdoor electrical installations that are open to unqualified persons shall comply with Parts I, II, and III of Article 225.

**(2) In Places Accessible to Qualified Persons Only.** Outdoor electrical installations that have exposed live parts shall be accessible to qualified persons only in accordance with the first paragraph of this section and shall comply with 110.34, 110.36, and 490.24.

**(D) Enclosed Equipment Accessible to Unqualified Persons.** Ventilating or similar openings in equipment shall be designed such that foreign objects inserted through these openings are deflected from energized parts. Where exposed to physical damage from vehicular traffic, suitable guards shall be provided. Nonmetallic or metal-enclosed equipment located outdoors and accessible to the general public shall be designed such that exposed nuts or bolts cannot be readily removed, permitting access to live parts. Where nonmetallic or metal-enclosed equipment is accessible to the general public and the bottom of the enclosure is less than 2.5 m (8 ft) above the floor or grade level, the enclosure door or hinged cover shall be kept locked. Doors and covers of enclosures used solely as pull boxes, splice boxes, or junction boxes shall be locked, bolted, or screwed on. Underground box covers that weigh over 45.4 kg (100 lb) shall be considered as meeting this requirement.

## 110.32 Work Space About Equipment

Sufficient space shall be provided and maintained about electrical equipment to permit ready and safe operation and maintenance of such equipment. Where energized parts are exposed, the minimum clear work space shall be not less than 2.0 m (6½ ft) high (measured vertically from the floor or platform) or not less than 914 mm (3 ft) wide (measured parallel to the equipment). The depth shall be as required in 110.34(A). In all cases, the work space shall permit at least a 90 degree opening of doors or hinged panels.

## 110.33 Entrance to Enclosures and Access to Working Space

**(A) Entrance.** At least one entrance to enclosures for electrical installations as described in 110.31 not less than 610 mm (24 in.) wide and 2.0 m (6½ ft) high shall be provided to give access to the working space about electrical equipment.

**(1) Large Equipment.** On switchboard and control panels exceeding 1.8 m (6 ft) in width, there shall be one entrance at each end of the equipment. A single entrance to the required working space shall be permitted where either of the conditions in 110.33(A)(1)(a) or (A)(1)(b) is met.

(a) *Unobstructed Exit.* Where the location permits a continuous and unobstructed way of exit travel, a single entrance to the working space shall be permitted.

(b) *Extra Working Space.* Where the depth of the working space is twice that required by 110.34(A), a single entrance shall be permitted. It shall be located so that the distance from the equipment to the nearest edge of the entrance is not less than the minimum clear distance specified in Table 110.34(A) for equipment operating at that voltage and in that condition.

**(2) Guarding.** Where bare energized parts at any voltage or insulated energized parts above 600 volts, nominal, to ground are located adjacent to such entrance, they shall be suitably guarded.

Section 110.33(A) contains requirements very similar to those of 110.26(C). For further information, see the commentary following 110.26(C)(2), most of which also is valid for installations over 600 volts.

**(3) Personnel Doors.** Where there is a personnel door(s) intended for entrance to and egress from the working space less than 7.6 m (25 ft) from the nearest edge of the working space, the door(s) shall open in the direction of egress and be equipped with panic bars, pressure plates, or other devices that are normally latched but open under simple pressure.

The measurement for the personnel door is made from the nearest edge of the working space. Not every electrical installation is in an equipment room. This section requires personnel doors that are up to 25 ft from the working space to have panic hardware and to open in the direction of egress from the area.

**(B) Access.** Permanent ladders or stairways shall be provided to give safe access to the working space around electrical equipment installed on platforms, balconies, or mezzanine floors or in attic or roof rooms or spaces.

## 110.34 Work Space and Guarding

**(A) Working Space.** Except as elsewhere required or permitted in this *Code*, equipment likely to require examination, adjustment, servicing, or maintenance while energized shall have clear working space in the direction of access to live parts of the electrical equipment and shall be not less

than specified in Table 110.34(A). Distances shall be measured from the live parts, if such are exposed, or from the enclosure front or opening if such are enclosed.

**TABLE 110.34(A) Minimum Depth of Clear Working Space at Electrical Equipment**

Nominal Voltage to Ground	Minimum Clear Distance		
	Condition 1	Condition 2	Condition 3
601–2500 V	900 mm (3 ft)	1.2 m (4 ft)	1.5 m (5 ft)
2501–9000 V	1.2 m (4 ft)	1.5 m (5 ft)	1.8 m (6 ft)
9001–25,000 V	1.5 m (5 ft)	1.8 m (6 ft)	2.8 m (9 ft)
25,001 V–75 kV	1.8 m (6 ft)	2.5 m (8 ft)	3.0 m (10 ft)
Above 75 kV	2.5 m (8 ft)	3.0 m (10 ft)	3.7 m (12 ft)

Note: Where the conditions are as follows:

**Condition 1** — Exposed live parts on one side of the working space and no live or grounded parts on the other side of the working space, or exposed live parts on both sides of the working space that are effectively guarded by insulating materials.

**Condition 2** — Exposed live parts on one side of the working space and grounded parts on the other side of the working space. Concrete, brick, or tile walls shall be considered as grounded.

**Condition 3** — Exposed live parts on both sides of the working space.

*Exception: Working space shall not be required in back of equipment such as dead-front switchboards or control assemblies where there are no renewable or adjustable parts (such as fuses or switches) on the back and where all connections are accessible from locations other than the back. Where rear access is required to work on nonelectrical parts on the back of enclosed equipment, a minimum working space of 762 mm (30 in.) horizontally shall be provided.*

The provisions of 110.34 are conditional, just like the requirements in 110.26; that is, some of the requirements are applicable only where the equipment “is likely to require examination, adjustment, servicing, or maintenance while energized.”

**(B) Separation from Low-Voltage Equipment.** Where switches, cutouts, or other equipment operating at 600 volts, nominal, or less are installed in a vault, room, or enclosure where there are exposed live parts or exposed wiring operating at over 600 volts, nominal, the high-voltage equipment shall be effectively separated from the space occupied by the low-voltage equipment by a suitable partition, fence, or screen.

*Exception: Switches or other equipment operating at 600 volts, nominal, or less and serving only equipment within the high-voltage vault, room, or enclosure shall be permitted to be installed in the high-voltage vault, room, or enclosure*

*without a partition, fence, or screen if accessible to qualified persons only.*

**(C) Locked Rooms or Enclosures.** The entrance to all buildings, vaults, rooms, or enclosures containing exposed live parts or exposed conductors operating at over 600 volts, nominal, shall be kept locked unless such entrances are under the observation of a qualified person at all times.

Where the voltage exceeds 600 volts, nominal, permanent and conspicuous warning signs shall be provided, reading as follows:

**DANGER — HIGH VOLTAGE — KEEP OUT**

Equipment used on circuits over 600 volts, nominal, and containing exposed live parts or exposed conductors is required to be located in a locked room or in an enclosure. The provisions for locking are not required if the room or enclosure is under observation at all times, as is the case with some engine rooms. Where the room or enclosure is accessible to other than qualified persons, the entry to the room and equipment is required to be provided with warning labels. See Exhibit 110.27.

**EXHIBIT 110.27** Enclosures of equipment operations at over 600 volts required to have the warning label specified in 110.31(B)(1). (Courtesy of the International Association of Electrical Inspectors)

**(D) Illumination.** Illumination shall be provided for all working spaces about electrical equipment. The lighting outlets shall be arranged so that persons changing lamps or making repairs on the lighting system are not endangered by live parts or other equipment.

The points of control shall be located so that persons are not likely to come in contact with any live part or moving part of the equipment while turning on the lights.

(E) **Elevation of Unguarded Live Parts.** Unguarded live parts above working space shall be maintained at elevations not less than required by Table 110.34(E).

**TABLE 110.34(E) Elevation of Unguarded Live Parts Above Working Space**

Nominal Voltage Between Phases	Elevation	
	m	ft
601–7500 V	2.8	9
7501–35,000 V	2.9	9 ft 6 in.
Over 35 kV	2.9 m + 9.5 mm/ kV above 35	9 ft 6 in. + 0.37 in./kV above 35

(F) **Protection of Service Equipment, Metal-Enclosed Power Switchgear, and Industrial Control Assemblies.** Pipes or ducts foreign to the electrical installation and requiring periodic maintenance or whose malfunction would endanger the operation of the electrical system shall not be located in the vicinity of the service equipment, metal-enclosed power switchgear, or industrial control assemblies. Protection shall be provided where necessary to avoid damage from condensation leaks and breaks in such foreign systems. Piping and other facilities shall not be considered foreign if provided for fire protection of the electrical installation.

### 110.36 Circuit Conductors

Circuit conductors shall be permitted to be installed in raceways; in cable trays; as metal-clad cable, as bare wire, cable, and busbars; or as Type MV cables or conductors as provided in 300.37, 300.39, 300.40, and 300.50. Bare live conductors shall comply with 490.24.

Insulators, together with their mounting and conductor attachments, where used as supports for wires, single-conductor cables, or busbars, shall be capable of safely withstanding the maximum magnetic forces that would prevail if two or more conductors of a circuit were subjected to short-circuit current.

Exposed runs of insulated wires and cables that have a bare lead sheath or a braided outer covering shall be supported in a manner designed to prevent physical damage to the braid or sheath. Supports for lead-covered cables shall be designed to prevent electrolysis of the sheath.

### 110.40 Temperature Limitations at Terminations

Conductors shall be permitted to be terminated based on the 90°C (194°F) temperature rating and ampacity as given in Table 310.60(C)(67) through Table 310.60(C)(86), unless otherwise identified.

## IV. Tunnel Installations over 600 Volts, Nominal

### 110.51 General

(A) **Covered.** The provisions of this part shall apply to the installation and use of high-voltage power distribution and utilization equipment that is portable, mobile, or both, such as substations, trailers, cars, mobile shovels, draglines, hoists, drills, dredges, compressors, pumps, conveyors, underground excavators, and the like.

(B) **Other Articles.** The requirements of this part shall be additional to, or amendatory of, those prescribed in Articles 100 through 490 of this *Code*.

(C) **Protection Against Physical Damage.** Conductors and cables in tunnels shall be located above the tunnel floor and so placed or guarded to protect them from physical damage.

### 110.52 Overcurrent Protection

Motor-operated equipment shall be protected from overcurrent in accordance with Parts III, IV, and V of Article 430. Transformers shall be protected from overcurrent in accordance with 450.3.

### 110.53 Conductors

High-voltage conductors in tunnels shall be installed in metal conduit or other metal raceway, Type MC cable, or other approved multiconductor cable. Multiconductor portable cable shall be permitted to supply mobile equipment.

### 110.54 Bonding and Equipment Grounding Conductors

(A) **Grounded and Bonded.** All non-current-carrying metal parts of electrical equipment and all metal raceways and cable sheaths shall be solidly grounded and bonded to all metal pipes and rails at the portal and at intervals not exceeding 300 m (1000 ft) throughout the tunnel.

(B) **Equipment Grounding Conductors.** An equipment grounding conductor shall be run with circuit conductors inside the metal raceway or inside the multiconductor cable jacket. The equipment grounding conductor shall be permitted to be insulated or bare.

### 110.55 Transformers, Switches, and Electrical Equipment

All transformers, switches, motor controllers, motors, rectifiers, and other equipment installed belowground shall be protected from physical damage by location or guarding.

### 110.56 Energized Parts

Bare terminals of transformers, switches, motor controllers, and other equipment shall be enclosed to prevent accidental contact with energized parts.

### 110.57 Ventilation System Controls

Electrical controls for the ventilation system shall be arranged so that the airflow can be reversed.

### 110.58 Disconnecting Means

A switch or circuit breaker that simultaneously opens all ungrounded conductors of the circuit shall be installed within sight of each transformer or motor location for disconnecting the transformer or motor. The switch or circuit breaker for a transformer shall have an ampere rating not less than the ampacity of the transformer supply conductors. The switch or circuit breaker for a motor shall comply with the applicable requirements of Article 430.

### 110.59 Enclosures

Enclosures for use in tunnels shall be dripproof, weatherproof, or submersible as required by the environmental conditions. Switch or contactor enclosures shall not be used as junction boxes or as raceways for conductors feeding through or tapping off to other switches, unless the enclosures comply with 312.8.

## V. Manholes and Other Electrical Enclosures Intended for Personnel Entry, All Voltages

Manhole working space requirements and issues for cabling and other equipment here parallel those same working space issues elsewhere in Article 110. For handhole installations, see Article 314.

### 110.70 General

Electrical enclosures intended for personnel entry and specifically fabricated for this purpose shall be of sufficient size to provide safe work space about electrical equipment with live parts that is likely to require examination, adjustment, servicing, or maintenance while energized. Such enclosures shall have sufficient size to permit ready installation or withdrawal of the conductors employed without damage to the conductors or to their insulation. They shall comply with the provisions of this part.

*Exception: Where electrical enclosures covered by Part V of this article are part of an industrial wiring system operating under conditions of maintenance and supervision that*

*ensure that only qualified persons monitor and supervise the system, they shall be permitted to be designed and installed in accordance with appropriate engineering practice. If required by the authority having jurisdiction, design documentation shall be provided.*

The provisions of Part V are conditional, just like the requirements in 110.26; that is, some of the requirements are applicable only where the equipment “is likely to require examination, adjustment, servicing, or maintenance while energized.”

### 110.71 Strength

Manholes, vaults, and their means of access shall be designed under qualified engineering supervision and shall withstand all loads likely to be imposed on the structures.

*Informational Note:* See ANSI C2-2007, *National Electrical Safety Code*, for additional information on the loading that can be expected to bear on underground enclosures.

### 110.72 Cabling Work Space

A clear work space not less than 900 mm (3 ft) wide shall be provided where cables are located on both sides, and not less than 750 mm (2½ ft) where cables are only on one side. The vertical headroom shall be not less than 1.8 m (6 ft) unless the opening is within 300 mm (1 ft), measured horizontally, of the adjacent interior side wall of the enclosure.

*Exception: A manhole containing only one or more of the following shall be permitted to have one of the horizontal work space dimensions reduced to 600 mm (2 ft) where the other horizontal clear work space is increased so the sum of the two dimensions is not less than 1.8 m (6 ft):*

- (1) Optical fiber cables as covered in Article 770
- (2) Power-limited fire alarm circuits supplied in accordance with 760.121
- (3) Class 2 or Class 3 remote-control and signaling circuits, or both, supplied in accordance with 725.121

### 110.73 Equipment Work Space

Where electrical equipment with live parts that is likely to require examination, adjustment, servicing, or maintenance while energized is installed in a manhole, vault, or other enclosure designed for personnel access, the work space and associated requirements in 110.26 shall be met for installations operating at 600 volts or less. Where the installation is over 600 volts, the work space and associated requirements in 110.34 shall be met. A manhole access cover that weighs over 45 kg (100 lb) shall be considered as meeting the requirements of 110.34(C).

### 110.74 Conductor Installation

Conductors installed in manholes and other enclosures intended for personnel entry shall be cabled, racked up, or arranged in an approved manner that provides ready and safe access for persons to enter for installation and maintenance. The installation shall comply with 110.74(A) or 110.74(B), as applicable.

**(A) 600 Volts, Nominal, or Less.** Wire bending space for conductors operating at 600 volts or less shall be provided in accordance with the requirements of 314.28.

**(B) Over 600 Volts, Nominal.** Conductors operating at over 600 volts shall be provided with bending space in accordance with 314.71(A) and (B), as applicable.

*Exception: Where 314.71(B) applies, each row or column of ducts on one wall of the enclosure shall be calculated individually, and the single row or column that provides the maximum distance shall be used.*

### 110.75 Access to Manholes

**(A) Dimensions.** Rectangular access openings shall not be less than 650 mm × 550 mm (26 in. × 22 in.). Round access openings in a manhole shall be not less than 650 mm (26 in.) in diameter.

*Exception: A manhole that has a fixed ladder that does not obstruct the opening or that contains only one or more of the following shall be permitted to reduce the minimum cover diameter to 600 mm (2 ft):*

- (1) Optical fiber cables as covered in Article 770
- (2) Power-limited fire alarm circuits supplied in accordance with 760.121
- (3) Class 2 or Class 3 remote-control and signaling circuits, or both, supplied in accordance with 725.121

**(B) Obstructions.** Manhole openings shall be free of protrusions that could injure personnel or prevent ready egress.

**(C) Location.** Manhole openings for personnel shall be located where they are not directly above electrical equipment

or conductors in the enclosure. Where this is not practicable, either a protective barrier or a fixed ladder shall be provided.

**(D) Covers.** Covers shall be over 45 kg (100 lb) or otherwise designed to require the use of tools to open. They shall be designed or restrained so they cannot fall into the manhole or protrude sufficiently to contact electrical conductors or equipment within the manhole.

**(E) Marking.** Manhole covers shall have an identifying mark or logo that prominently indicates their function, such as “electric.”

### 110.76 Access to Vaults and Tunnels

**(A) Location.** Access openings for personnel shall be located where they are not directly above electrical equipment or conductors in the enclosure. Other openings shall be permitted over equipment to facilitate installation, maintenance, or replacement of equipment.

**(B) Locks.** In addition to compliance with the requirements of 110.34, if applicable, access openings for personnel shall be arranged such that a person on the inside can exit when the access door is locked from the outside, or in the case of normally locking by padlock, the locking arrangement shall be such that the padlock can be closed on the locking system to prevent locking from the outside.

### 110.77 Ventilation

Where manholes, tunnels, and vaults have communicating openings into enclosed areas used by the public, ventilation to open air shall be provided wherever practicable.

### 110.78 Guarding

Where conductors or equipment, or both, could be contacted by objects falling or being pushed through a ventilating grating, both conductors and live parts shall be protected in accordance with the requirements of 110.27(A)(2) or 110.31(B)(1), depending on the voltage.

### 110.79 Fixed Ladders

Fixed ladders shall be corrosion resistant.

### 200.1 Scope

This article provides requirements for the following:

- (1) Identification of terminals
- (2) Grounded conductors in premises wiring systems
- (3) Identification of grounded conductors

Informational Note: See Article 100 for definitions of *Grounded Conductor*, *Equipment Grounding Conductor*, and *Grounding Electrode Conductor*.

The requirements of Article 200 cover the grounded conductor's use in premises wiring systems and the acceptable methods for identifying grounded conductors and the terminals to which they are connected. Identification of grounded conductors is a long-standing, fundamental safety concept that helps ensure proper connection of the conductor throughout an electrical system. Proper connection and maintaining correct polarity are essential to ensuring safe interface with wiring devices, appliances, and portable and permanently installed luminaires.

In accordance with the Article 100 definition of *grounded conductor*, it is a conductor that is intentionally grounded, meaning that it is intentionally connected to the earth.

The grounded conductor is often, but not always, the neutral conductor. As defined in Article 100, a *neutral conductor* is one that is connected to the *neutral point* of an electrical system. For example, in a single-phase 2-wire or in a 3-phase corner-grounded delta system, the intentionally grounded conductor is not a neutral conductor because it is not connected to a system neutral point. Through its very nature of being connected to the same grounding electrode system as the non-current-carrying metal parts of electrical equipment, there is generally no potential difference between the grounded conductor and those grounded metal parts. However, unlike an equipment grounding conductor, the grounded conductor is a circuit conductor and as such is a current-carrying conductor. Whether it is referred to as the grounded conductor or as the neutral conductor, the white or gray marking on a circuit conductor indicates it is a conductor that is intentionally connected to the earth.

Electric shock injuries and electrocutions have occurred as a result of working on the grounded conductor while the circuit is energized. Extreme caution must be exercised where the grounded (neutral) conductor is part of a multiwire branch circuit [see 210.4(B) on disconnecting means for multiwire branch circuits], and it should be noted that 300.13 does not permit the wiring terminals of a device, such as a receptacle, to be the means of maintaining the continuity of the grounded conductor in that type of branch circuit.

In addition to the requirements in this article, the use

and installation of the grounded conductor are covered extensively by the requirements in Article 250.

## 200.2 General

Grounded conductors shall comply with 200.2(A) and (B).

**(A) Insulation.** The grounded conductor, where insulated, shall have insulation that is (1) suitable, other than color, for any ungrounded conductor of the same circuit on circuits of less than 1000 volts or impedance grounded neutral systems of 1 kV and over, or (2) rated not less than 600 volts for solidly grounded neutral systems of 1 kV and over as described in 250.184(A).

**(B) Continuity.** The continuity of a grounded conductor shall not depend on a connection to a metallic enclosure, raceway, or cable armor.

Informational Note: See 300.13(B) for the continuity of grounded conductors used in multiwire branch circuits.

Section 200.2(B) requires grounded conductors be connected to a terminal or busbar that is specifically intended and identified for connection of grounded or neutral conductors. Because grounded conductors are current carrying, connecting them to a separate equipment grounding terminal or bar (that is directly connected to a metal cabinet or enclosure) results in the enclosure becoming a neutral conductor between the equipment grounding terminal and the point of connection for the grounded conductor.

## 200.3 Connection to Grounded System

Premises wiring shall not be electrically connected to a supply system unless the latter contains, for any grounded conductor of the interior system, a corresponding conductor that is grounded. For the purpose of this section, *electrically connected* shall mean connected so as to be capable of carrying current, as distinguished from connection through electromagnetic induction.

*Exception: Listed utility-interactive inverters identified for use in distributed resource generation systems such as photovoltaic and fuel cell power systems shall be permitted to be connected to premises wiring without a grounded conductor where the connected premises wiring or utility system includes a grounded conductor.*

Grounded conductors of premises wiring are required to be connected to the supply system (service or applicable separately derived system) grounded conductor to ensure a common, continuous, grounded system.

## 200.4 Neutral Conductors

Neutral conductors shall not be used for more than one branch circuit, for more than one multiwire branch circuit, or for more than one set of ungrounded feeder conductors unless specifically permitted elsewhere in this Code.

This section specifies that an individual neutral conductor be provided for each two-wire and multiwire branch circuit and feeder unless a common or shared neutral is permitted elsewhere in the Code. There are specific provisions in 215.4 and 225.7 permitting multiple circuits to have a common or shared neutral conductor. This provision does not require that a neutral conductor be installed with the ungrounded circuit conductors if line-to-neutral loads are not supplied by the branch circuit or feeder, nor does it prohibit the use of multiwire circuits as long as each multiwire circuit has its own neutral conductor. See Article 100 for the definition of a multiwire branch circuit.

The concern with multiple circuits sharing a neutral conductor is the possibility of overloading the neutral conductor. Typically, an overcurrent protective device is not present, nor is it required to be installed in series with the neutral conductor. Therefore, an overload condition can exist without being detected or responded to and insulation damage can occur. Because of the electrical relationship between the ungrounded conductors and the neutral conductor in multiwire single-phase and three-phase circuits, the possibility of overload does not exist except where the load characteristics result in additive harmonic currents in the neutral conductor.

## 200.6 Means of Identifying Grounded Conductors

**(A) Sizes 6 AWG or Smaller.** An insulated grounded conductor of 6 AWG or smaller shall be identified by one of the following means:

- (1) A continuous white outer finish.
- (2) A continuous gray outer finish.
- (3) Three continuous white stripes along the conductor's entire length on other than green insulation.
- (4) Wires that have their outer covering finished to show a white or gray color but have colored tracer threads in the braid identifying the source of manufacture shall be considered as meeting the provisions of this section.

The general rule of 200.6(A) requires insulated conductors 6 AWG or smaller to be white or gray for their entire length where they are used as grounded conductors. The Code also permits three continuous white stripes along the entire length of conductor insulation that is colored other than

green as a means to identify a conductor as the grounded conductor. Using three white stripes for identification is permitted for all conductor sizes and is the method most typically employed by a wire or cable manufacturer.

Other methods of identification are also permitted in 200.6(A). For example, the grounded conductor of mineral-insulated (MI) cable, due to its unique construction, is permitted to be identified at the time of installation. Aerial cable may have its grounded conductor identified by a ridge along its insulated surface, and fixture wires are permitted to have the grounded conductor identified by various methods, including colored insulation, stripes on the insulation, colored braid, colored separator, and tinned conductors. These identification methods are found in 402.8 and explained in detail in 400.22(A) through (E).

For 6 AWG or smaller, identification of the grounded conductor solely through the use of white or gray marking tape or other distinctive white or gray marking applied at the time of installation is not permitted, except as described for flexible cords and multiconductor cables in 200.6(C) and (E), Exception No. 1, and for single conductors in outdoor photovoltaic power installations in accordance with 200.6(A)(2).

- (5) The grounded conductor of a mineral-insulated, metal-sheathed cable shall be identified at the time of installation by distinctive marking at its terminations.
- (6) A single-conductor, sunlight-resistant, outdoor-rated cable used as a grounded conductor in photovoltaic power systems, as permitted by 690.31, shall be identified at the time of installation by distinctive white marking at all terminations.
- (7) Fixture wire shall comply with the requirements for grounded conductor identification as specified in 402.8.
- (8) For aerial cable, the identification shall be as above, or by means of a ridge located on the exterior of the cable so as to identify it.

**(B) Sizes 4 AWG or Larger.** An insulated grounded conductor 4 AWG or larger shall be identified by one of the following means:

- (1) A continuous white outer finish.
- (2) A continuous gray outer finish
- (3) Three continuous white stripes along its entire length on other than green insulation.
- (4) At the time of installation, by a distinctive white or gray marking at its terminations. This marking shall encircle the conductor or insulation.

The general rule of 200.6(B) requires that insulated grounded conductors 4 AWG and larger be identified by one of three

acceptable methods. As allowed by 200.6(A) for 6 AWG and smaller insulated conductors, 200.6(B) permits the use of a continuous white or gray color along the entire length of the conductor insulation or the use of three continuous white stripes on the entire length of the insulated (other than green colored insulation) conductor. The most common method used by installers to identify a single conductor as a grounded conductor is application of a white or gray marking to the insulation at all termination points at the time of installation. To be clearly visible, this field-applied white or gray marking must completely encircle the conductor insulation. This coloring can be applied by using marking tape or by painting the insulation. This method of identification is shown in Exhibit 200.1.

**EXHIBIT 200.1** Field-applied identification, as permitted by 200.6(B), of a 4 AWG conductor to identify it as the grounded conductor.

**(C) Flexible Cords.** An insulated conductor that is intended for use as a grounded conductor, where contained within a flexible cord, shall be identified by a white or gray outer finish or by methods permitted by 400.22.

**(D) Grounded Conductors of Different Systems.** Where grounded conductors of different systems are installed in the same raceway, cable, box, auxiliary gutter, or other type of enclosure, each grounded conductor shall be identified by system. Identification that distinguishes each system grounded conductor shall be permitted by one of the following means:

- (1) One system grounded conductor shall have an outer covering conforming to 200.6(A) or (B).
- (2) The grounded conductor(s) of other systems shall have a different outer covering conforming to 200.6(A) or 200.6(B) or by an outer covering of white or gray with a readily distinguishable colored stripe other than green running along the insulation.
- (3) Other and different means of identification as allowed by 200.6(A) or (B) that will distinguish each system grounded conductor.

The means of identification shall be documented in a manner that is readily available or shall be permanently posted where the conductors of different systems originate.

Section 200.6(D) identifies the requirements for grounded conductors installed in the same enclosure. Exhibit 200.2 illustrates an enclosure containing grounded conductors of two different systems that are distinguished from each other by white and gray colored insulation. The grounded conductors of the different systems are identified by color through the use of white and gray colored insulation, one of the methods specified by 200.6(D). Gray and white colored insulation on conductors is recognized by the *Code* as two separate means of identifying grounded conductors.

**EXHIBIT 200.2** Grounded conductors of different systems in the same enclosure.

The use of colored stripes (other than green) on white insulation for the entire conductor insulation length is also an acceptable method to distinguish one system grounded conductor from one with white insulation or white marking. This requirement applies only where grounded conductors of different systems are installed in a common enclosure, such as a junction or pull box or a wireway. Where grounded conductors of different supply systems are installed in a common enclosure, identifying the grounded conductors associated with one system from the grounded conductors of another system helps to ensure proper system connections. As more systems with grounded conductors are installed in a common enclosure, it becomes necessary to employ more means to distinguish each system grounded conductor from the other system grounded conductors in that enclosure. The only acceptable means of identifying grounded conductors are those specified in 200.6(A) and (B).

The *Code* requires the identification method or scheme used to distinguish the grounded conductors of different systems to be posted at the equipment (e.g., a panelboard, switchboard, or similar distribution equipment) where the feeders or branch circuits originate. Alternatively, the means of identification is permitted to be included in a facility's

electrical system documentation as long as the documents can be readily obtained. The industry practice of using white for lower-voltage systems and gray for higher-voltage systems is permitted but not mandated by the *Code*. Exhibit 200.3 is an example of a permanent label posted at electrical distribution equipment, indicating the identification scheme for the grounded conductors of each nominal voltage system. Because this equipment contains two nominal voltage systems, the grounded (neutral) conductor of each system must be identified in a manner that distinguishes it from the grounded conductor(s) of other systems in that equipment.

VOLTAGE		VOLTAGE	
208Y/120V		480Y/277V	
PHASE A	BLACK	PHASE A	BROWN
PHASE B	RED	PHASE B	ORANGE
PHASE C	BLUE	PHASE C	YELLOW
NEUTRAL	WHITE	NEUTRAL	GREY

**EXHIBIT 200.3** A label on a piece of equipment containing conductors of two nominal voltage systems that provides the required information on how grounded and ungrounded conductors of one nominal voltage system are identified and distinguished from the conductors of the other nominal voltage system.

#### (E) Grounded Conductors of Multiconductor Cables.

The insulated grounded conductors in a multiconductor cable shall be identified by a continuous white or gray outer finish or by three continuous white stripes on other than green insulation along its entire length. Multiconductor flat cable 4 AWG or larger shall be permitted to employ an external ridge on the grounded conductor.

*Exception No. 1: Where the conditions of maintenance and supervision ensure that only qualified persons service the installation, grounded conductors in multiconductor cables shall be permitted to be permanently identified at their terminations at the time of installation by a distinctive white marking or other equally effective means.*

Exception No. 1 to 200.6(E) permits identifying grounded conductors of multiconductor cables at termination locations. This exception allows identification of a conductor

that is part of a multiconductor cable as the grounded conductor at the time of installation by use of a distinctive white marking as shown in Exhibit 200.4 or other equally effective means, such as numbering, lettering, or tagging. Exception No. 1 to 200.6(E) applies only to installations in facilities that have a regulated system of maintenance and supervision performed by qualified persons. Permission to re-identify a conductor within a cable assembly is not predicated on the conductor size.

**EXHIBIT 200.4** Field-applied identification to the conductor of a multiconductor armored cable to be used as the grounded conductor as permitted by 200.6(E), Exception No. 1.

*Exception No. 2: The grounded conductor of a multiconductor varnished-cloth-insulated cable shall be permitted to be identified at its terminations at the time of installation by a distinctive white marking or other equally effective means.*

**Informational Note:** The color gray may have been used in the past as an ungrounded conductor. Care should be taken when working on existing systems.

The term *natural gray* was changed to *gray* in the 2002 *Code* because the phrase “natural gray outer finish” was deemed obsolete. This change reserves all shades of gray insulation and marking for grounded conductors. The informational note following 200.6(E) warns the user to exercise caution when working on existing systems because gray may have been used to identify ungrounded conductors in those systems.

## 200.7 Use of Insulation of a White or Gray Color or with Three Continuous White Stripes

**(A) General.** The following shall be used only for the grounded circuit conductor, unless otherwise permitted in 200.7(B) and (C):

- (1) A conductor with continuous white or gray covering
- (2) A conductor with three continuous white stripes on other than green insulation
- (3) A marking of white or gray color at the termination

**(B) Circuits of Less Than 50 Volts.** A conductor with white or gray color insulation or three continuous white stripes or having a marking of white or gray at the termination for circuits of less than 50 volts shall be required to be grounded only as required by 250.20(A).

**(C) Circuits of 50 Volts or More.** The use of insulation that is white or gray or that has three continuous white stripes for other than a grounded conductor for circuits of 50 volts or more shall be permitted only as in (1) and (2).

- (1) If part of a cable assembly that has the insulation permanently reidentified to indicate its use as an ungrounded conductor by marking tape, painting, or other effective means at its termination and at each location where the conductor is visible and accessible. Identification shall encircle the insulation and shall be a color other than white, gray, or green. If used for single-pole, 3-way or 4-way switch loops, the reidentified conductor with white or gray insulation or three continuous white stripes shall be used only for the supply to the switch, but not as a return conductor from the switch to the outlet.

Where the wiring method is a cable assembly, such as Type AC, Type MC, or Type NM cables, 200.7(C)(1) allows a conductor with a white or gray colored insulation to be used as an ungrounded conductor. Examples of where this provision is used include water heaters, electric heat, motors, and switch loops. The insulation has to be re-identified to avoid confusing it with conductors having white or gray insulation that are grounded or neutral conductors at switch and outlet points and at other points in the wiring system where the conductors are accessible. In previous editions, the *Code* permitted switch loops using a white insulated conductor to serve as an ungrounded conductor supplying the switch but not as the return ungrounded conductor to supply the lighting outlet. Prior to the 1999 *NEC*, re-identification of a white conductor used for this purpose was not required. However, electronic switching devices with small power supplies are available that can be installed at switch locations. These devices require a grounded conductor in order to power the internal components, and they help in clearly distinguishing a grounded conductor from ungrounded conductors, which aids in properly connecting such devices. Although in switch loops the conductor with white or gray insulation is re-identified at all accessible locations to indicate that it is being used as an ungrounded conductor, it is only permitted to be used to supply the switch and cannot be used as the switched ungrounded conductor at the controlled outlet. Exhibit 200.5 shows a switch location where the conductor with the white insulation has been re-identified at the termination to indicate that it is the ungrounded supply conductor run to the switch.

**EXHIBIT 200.5** The re-identified conductor at a switch location, limited to use only as the ungrounded conductor that supplies the switch.

(2) A flexible cord, having one conductor identified by a white or gray outer finish or three continuous white stripes or by any other means permitted by 400.22, that is used for connecting an appliance or equipment permitted by 400.7. This shall apply to flexible cords connected to outlets whether or not the outlet is supplied by a circuit that has a grounded conductor.

**Informational Note:** The color gray may have been used in the past as an ungrounded conductor. Care should be taken when working on existing systems.

## 200.9 Means of Identification of Terminals

The identification of terminals to which a grounded conductor is to be connected shall be substantially white in color. The identification of other terminals shall be of a readily distinguishable different color.

*Exception:* Where the conditions of maintenance and supervision ensure that only qualified persons service the installations, terminals for grounded conductors shall be permitted to be permanently identified at the time of installation by a distinctive white marking or other equally effective means.

## 200.10 Identification of Terminals

**(A) Device Terminals.** All devices, excluding panelboards, provided with terminals for the attachment of conductors and intended for connection to more than one side of the circuit shall have terminals properly marked for identification, unless the electrical connection of the terminal intended to be connected to the grounded conductor is clearly evident.

*Exception:* Terminal identification shall not be required for devices that have a normal current rating of over 30 amperes, other than polarized attachment plugs and polarized receptacles for attachment plugs as required in 200.10(B).

**(B) Receptacles, Plugs, and Connectors.** Receptacles, polarized attachment plugs, and cord connectors for plugs and polarized plugs shall have the terminal intended for connection to the grounded conductor identified as follows:

- (1) Identification shall be by a metal or metal coating that is substantially white in color or by the word *white* or the letter *W* located adjacent to the identified terminal.
- (2) If the terminal is not visible, the conductor entrance hole for the connection shall be colored white or marked with the word *white* or the letter *W*.

The acceptable means of terminal identification other than colored terminal screws allows the plating of all screws and terminals to meet other requirements of specific applications, such as corrosion-resistant devices.

**Informational Note:** See 250.126 for identification of wiring device equipment grounding conductor terminals.

**(C) Screw Shells.** For devices with screw shells, the terminal for the grounded conductor shall be the one connected to the screw shell.

**(D) Screw Shell Devices with Leads.** For screw shell devices with attached leads, the conductor attached to the screw shell shall have a white or gray finish. The outer finish of the other conductor shall be of a solid color that will not be confused with the white or gray finish used to identify the grounded conductor.

**Informational Note:** The color gray may have been used in the past as an ungrounded conductor. Care should be taken when working on existing systems.

**(E) Appliances.** Appliances that have a single-pole switch or a single-pole overcurrent device in the line or any line-connected screw shell lampholders, and that are to be connected by (1) a permanent wiring method or (2) field-installed attachment plugs and cords with three or more

wires (including the equipment grounding conductor), shall have means to identify the terminal for the grounded circuit conductor (if any).

### 200.11 Polarity of Connections

No grounded conductor shall be attached to any terminal or lead so as to reverse the designated polarity.

## I. General Provisions

### 210.1 Scope

This article covers branch circuits except for branch circuits that supply only motor loads, which are covered in Article 430. Provisions of this article and Article 430 apply to branch circuits with combination loads.

Although 210.1 specifies that Article 210 provides the requirements for branch circuits, 90.3 indicates that the requirements in Chapters 5, 6, and 7 may amend or modify the general requirements of Chapters 1 through 4. An example of how the *NEC* arrangement works is found in 668.3(C)(1) covering electrolytic cell line conductors, cells, cell line attachments, and the wiring of auxiliary equipment and devices within the cell line working zone. This type of equipment is not covered by the general branch-circuit provisions of Article 210; rather, the requirements of Article 668 address the unique concerns associated with electrolytic cells.

### 210.2 Other Articles for Specific-Purpose Branch Circuits

Branch circuits shall comply with this article and also with the applicable provisions of other articles of this *Code*. The provisions for branch circuits supplying equipment listed in Table 210.2 amend or supplement the provisions in this article and shall apply to branch circuits referred to therein.

### 210.3 Rating

Branch circuits recognized by this article shall be rated in accordance with the maximum permitted ampere rating or setting of the overcurrent device. The rating for other than individual branch circuits shall be 15, 20, 30, 40, and 50 amperes. Where conductors of higher ampacity are used for any reason, the ampere rating or setting of the specified overcurrent device shall determine the circuit rating.

Where the length of the branch-circuit conductors is determined to cause a voltage drop that reduces the efficiency or performance of electrically operated equipment, larger conductors with a higher ampacity are commonly used. For example, a branch circuit wired with 10 AWG copper conductors has an allowable ampacity of at least 30 amperes per Table 310.15(B)(16). However, if the branch-circuit overcurrent protective device is a 20-ampere circuit breaker or fuse, the rating of this branch circuit is 20 amperes, based on the size or rating of the overcurrent protective device.

*Exception: Multioutlet branch circuits greater than 50 amperes shall be permitted to supply nonlighting outlet loads on industrial premises where conditions of maintenance and*

**TABLE 210.2 Specific-Purpose Branch Circuits**

Equipment	Article	Section
Air-conditioning and refrigerating equipment		440.6, 440.31, 440.32
Audio signal processing, amplification, and reproduction equipment		640.8
Busways		368.17
Circuits and equipment operating at less than 50 volts	720	
Central heating equipment other than fixed electric space-heating equipment		422.12
Class 1, Class 2, and Class 3 remote-control, signaling, and power-limited circuits	725	
Cranes and hoists		610.42

Mobile homes, manufactured homes, and mobile home parks	550	
Motion picture and television studios and similar locations	530	
Motors, motor circuits, and controllers	430	
Pipe organs		650.7
Recreational vehicles and recreational vehicle parks	551	
Switchboards and panelboards		408.52
Theaters, audience areas of motion picture and television studios, and similar locations		520.41, 520.52, 520.62
X-ray equipment		660.2, 517.73

*supervision ensure that only qualified persons service the equipment.*

A common practice at industrial premises is to provide several single receptacles with ratings of 50 amperes or higher

on a single branch circuit, to allow quick relocation of equipment for production or maintenance use, such as in the case of electric welders. Generally, only one piece of equipment at a time is supplied from this type of receptacle circuit. The type of receptacle used in this situation is generally a configuration known as a pin-and-sleeve receptacle, although the *Code* does not preclude the use of other configurations and designs. Pin-and-sleeve receptacles may or may not be horsepower rated.

## 210.4 Multiwire Branch Circuits

**(A) General.** Branch circuits recognized by this article shall be permitted as multiwire circuits. A multiwire circuit shall be permitted to be considered as multiple circuits. All conductors of a multiwire branch circuit shall originate from the same panelboard or similar distribution equipment.

**Informational Note:** A 3-phase, 4-wire, wye-connected power system used to supply power to nonlinear loads may necessitate that the power system design allow for the possibility of high harmonic currents on the neutral conductor.

The informational note to 210.4 acknowledges that power supplies for equipment such as computers, printers, and adjustable-speed motor drives can introduce harmonic currents in the system neutral conductor. The resulting total harmonic distortion current could exceed the load current of the device itself. See the commentary following 310.15(B)(5)(c) for a discussion of neutral conductor ampacity.

**(B) Disconnecting Means.** Each multiwire branch circuit shall be provided with a means that will simultaneously disconnect all ungrounded conductors at the point where the branch circuit originates.

All ungrounded conductors of a multiwire branch circuit are required to be simultaneously disconnected to reduce the risk of shock to personnel working on equipment supplied by a multiwire branch circuit. The simultaneous disconnecting means requirement takes the guesswork out of ensuring safe conditions for maintenance. In former editions of the *NEC*, this requirement applied only where the multiwire branch circuit supplied equipment mounted to a common yoke or strap.

For a single-phase installation, the disconnecting means could be two single-pole circuit breakers with an identified handle tie or a two-pole circuit breaker, as shown in Exhibit 210.1 (top), or by a 2-pole switch, as shown in Exhibit 210.1 (bottom). For a 3-phase installation, a 3-pole circuit breaker, three single-pole circuit breakers with an identified handle tie, or a three-pole switch provides the required simultane-

**EXHIBIT 210.1** Two examples where 210.4(B) requires the simultaneous disconnection of all ungrounded conductors to multiwire branch circuits supplying more than one device or equipment.

ous opening of the ungrounded conductors. The simultaneous opening of all “hot” conductors at the panelboard effectively protects personnel from inadvertent contact with an energized conductor or device terminal during servicing.

**Informational Note:** See 240.15(B) for information on the use of single-pole circuit breakers as the disconnecting means.

**(C) Line-to-Neutral Loads.** Multiwire branch circuits shall supply only line-to-neutral loads.

*Exception No. 1:* A multiwire branch circuit that supplies only one utilization equipment.

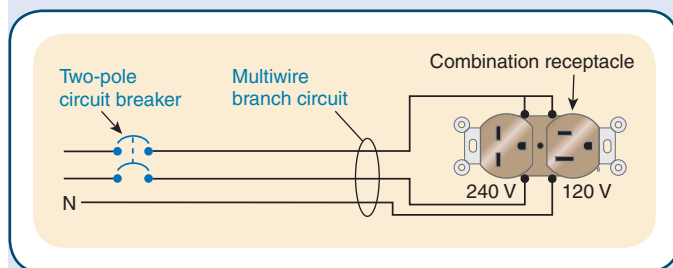

*Exception No. 2:* Where all ungrounded conductors of the multiwire branch circuit are opened simultaneously by the branch-circuit overcurrent device.

**Informational Note:** See 300.13(B) for continuity of grounded conductor on multiwire circuits.

The term *multiwire branch circuit* is defined in Article 100 as “a branch circuit that consists of two or more ungrounded conductors that have a voltage between them, and a grounded conductor that has equal voltage between it and

each ungrounded conductor of the circuit and that is connected to the neutral or grounded conductor of the system.” Although defined as “a” branch circuit, 210.4(A) permits a multiwire branch circuit to be considered as multiple circuits and could be used, for instance, to satisfy the requirement for providing two small-appliance branch circuits for countertop receptacle outlets in a dwelling unit kitchen.

The circuit most commonly used as a multiwire branch circuit consists of two ungrounded conductors and one grounded conductor supplied from a 120/240-volt, single-phase, 3-wire system. Such multiwire circuits supply appliances that have both line-to-line and line-to-neutral connected loads, such as electric ranges and clothes dryers, and also supply loads that are line-to-neutral connected only, such as the split-wired combination device shown in Exhibit 210.1 (bottom). A multiwire branch circuit is also permitted to supply a device with a 250-volt receptacle (line-to-line) and a 125-volt receptacle (line-to-neutral), as shown in Exhibit 210.2, provided the branch-circuit overcurrent device simultaneously opens both of the ungrounded conductors.

**EXHIBIT 210.2** An example of 210.4(C), Exception No. 2, which permits a multiwire branch circuit to supply line-to-neutral and line-to-line connected loads, provided the ungrounded conductors are opened simultaneously by the branch-circuit overcurrent device.

Multiwire branch circuits have many advantages, including using three wires to do the work of four (in place of two 2-wire circuits), less raceway fill, easier balancing and phasing of a system, and less voltage drop. See the commentary following 215.2(A)(4), Informational Note No. 3, for further information on voltage drop for branch circuits.

Multiwire branch circuits may be derived from a 120/240-volt, single-phase; a 208Y/120-volt and 480Y/277-volt, 3-phase, 4-wire; or a 240/120-volt, 3-phase, 4-wire delta system. Section 210.11(B) requires multiwire branch circuits to be properly balanced. If two ungrounded conductors and a common neutral are used as a multiwire branch circuit supplied from a 208Y/120-volt, 3-phase, 4-wire system, the neutral carries the same current as the phase conductor with the highest current and, therefore, should be the same size. The neutral for a 2-phase, 3-wire or a 2-phase, 5-wire circuit must be sized to carry 140 percent of the am-

per rating of the circuit, as required by 220.61(A), Exception. See the commentary following 210.4(A), Informational Note, for further information on 3-phase, 4-wire system neutral conductors.

If loads are connected line-to-line (i.e., utilization equipment connected between 2 or 3 phases), 2-pole or 3-pole circuit breakers are required to disconnect all ungrounded conductors simultaneously. In testing 240-volt equipment, it is quite possible not to realize that the circuit is still energized with 120 volts if one pole of the overcurrent device is open. See 210.10 and 240.15(B) for further information on circuit breaker overcurrent protection of ungrounded conductors. Other precautions concerning device removal on multiwire branch circuits are found in the commentary following 300.13(B).

**(D) Grouping.** The ungrounded and grounded circuit conductors of each multiwire branch circuit shall be grouped by cable ties or similar means in at least one location within the panelboard or other point of origination.

*Exception:* The requirement for grouping shall not apply if the circuit enters from a cable or raceway unique to the circuit that makes the grouping obvious.

## 210.5 Identification for Branch Circuits

**(A) Grounded Conductor.** The grounded conductor of a branch circuit shall be identified in accordance with 200.6.

**(B) Equipment Grounding Conductor.** The equipment grounding conductor shall be identified in accordance with 250.119.

**(C) Identification of Ungrounded Conductors.** Ungrounded conductors shall be identified in accordance with 210.5(C)(1), (2), and (3).

**(1) Application.** Where the premises wiring system has branch circuits supplied from more than one nominal voltage system, each ungrounded conductor of a branch circuit shall be identified by phase or line and system at all termination, connection, and splice points.

**(2) Means of Identification.** The means of identification shall be permitted to be by separate color coding, marking tape, tagging, or other approved means.

**(3) Posting of Identification Means.** The method utilized for conductors originating within each branch-circuit panelboard or similar branch-circuit distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each branch-circuit panelboard or similar branch-circuit distribution equipment.

The requirement in 210.5(C) to identify ungrounded branch-circuit conductors covers all branch-circuit configurations and is not applicable to only multiwire circuits. The identification requirement applies only to those premises that have more than one nominal voltage system supplying branch circuits (e.g., a 208Y/120-volt system and a 480Y/277-volt system) and requires that the conductors be identified by system and phase. Unlike the requirement of 200.6(D) for identifying the grounded conductors supplied from different voltage systems, application of this rule is not predicated on the different system conductors sharing a common raceway, cabinet, or enclosure.

The method of identification can be unique to the premises, and although color coding is a popular method, other types of marking or tagging are acceptable alternatives. It is intended that whatever method of identification is used, it be consistent throughout the premises. To that end, the identification legend is required to be posted at each branch-circuit panelboard or other equipment from which branch circuits are supplied or it is permitted to be documented in an on-site manual, log, or other form of record that is readily available to service personnel. Where posted at electrical distribution equipment, the marking required by this section only has to describe the identification scheme for the ungrounded conductors supplied from that particular equipment. The basis for this requirement is to provide a higher level of safety for personnel working on premises electrical systems having ungrounded conductors supplied from multiple nominal voltage systems.

Exhibit 210.3 shows an example of two different nominal voltage systems in a building. Each ungrounded system conductor is identified by color-coded marking tape. A label indicating the means of the identification is permanently located at each panelboard.

## 210.6 Branch-Circuit Voltage Limitations

The nominal voltage of branch circuits shall not exceed the values permitted by 210.6(A) through (E).

**(A) Occupancy Limitation.** In dwelling units and guest rooms or guest suites of hotels, motels, and similar occupancies, the voltage shall not exceed 120 volts, nominal, between conductors that supply the terminals of the following:

- (1) Luminaires
- (2) Cord-and-plug-connected loads 1440 volt-amperes, nominal, or less or less than  $\frac{1}{4}$  hp

The term *similar occupancies* in 210.6(A) refers to sleeping rooms in dormitories, fraternities, sororities, nursing homes, and other such facilities. This requirement is intended to reduce the exposure of residents in dwellings and similar oc-

**EXHIBIT 210.3** Examples of accessible (ungrounded) phase conductors identified by marking tape at a junction or outlet location where the conductors will be spliced or terminated.

cupancies to electric shock hazards when using or servicing permanently installed luminaires and cord-and-plug-connected portable lamps and appliances.

Small loads, such as those of 1440 volt-amperes or less and motors of less than  $\frac{1}{4}$  horsepower, are limited to 120-volt circuits. High-wattage cord-and-plug-connected loads, such as electric ranges, clothes dryers, and some window air conditioners, may be connected to a 208-volt or 240-volt circuit.

**(B) 120 Volts Between Conductors.** Circuits not exceeding 120 volts, nominal, between conductors shall be permitted to supply the following:

- (1) The terminals of lampholders applied within their voltage ratings

Section 210.6(B)(1) allows lampholders to be used only within their voltage ratings. See the commentary following 210.6(C)(2) for details on voltage limitations for listed incandescent luminaires.

- (2) Auxiliary equipment of electric-discharge lamps

Auxiliary equipment includes ballasts and starting devices for fluorescent and high-intensity-discharge (e.g., mercury vapor, metal halide, and sodium) lamps.

- (3) Cord-and-plug-connected or permanently connected utilization equipment

**(C) 277 Volts to Ground.** Circuits exceeding 120 volts, nominal, between conductors and not exceeding 277 volts, nominal, to ground shall be permitted to supply the following:

- (1) Listed electric-discharge or listed light-emitting diode-type luminaires

Section 210.6(C)(1) allows listed electric-discharge and listed light-emitting diode-type (LED) luminaires to be used only within their ratings. This provision covers many of the typical strip or lay-in type fluorescent luminaires. See 225.7(C) and (D) for additional restrictions on the installation of outdoor luminaires.

- (2) Listed incandescent luminaires, where supplied at 120 volts or less from the output of a stepdown autotransformer that is an integral component of the luminaire and the outer shell terminal is electrically connected to a grounded conductor of the branch circuit

Section 210.6(C)(2) permits an incandescent luminaire on a 277-volt circuit only if it is a listed luminaire with an integral autotransformer and an output to the lampholder that does not exceed 120 volts. In this application, the autotransformer supplies 120 volts to the lampholder, and the grounded conductor is connected to the screw shell of the lampholder. This application is similar to a branch circuit derived from an autotransformer, except that the 120-volt circuit is the internal wiring of the luminaire.

- (3) Luminaires equipped with mogul-base screw shell lampholders  
 (4) Lampholders, other than the screw shell type, applied within their voltage ratings  
 (5) Auxiliary equipment of electric-discharge lamps  
 (6) Cord-and-plug-connected or permanently connected utilization equipment

Exhibit 210.4 shows some examples of luminaires permitted to be connected to branch circuits. Medium-base screw shell lampholders cannot be directly connected to 277-volt branch circuits. Other types of lampholders may be connected to 277-volt circuits but only if the lampholders have a 277-volt rating. A 277-volt branch circuit may be connected to a listed electric-discharge fixture or to a listed autotransformer-type incandescent fixture with a medium-base screw shell lampholder.

Typical examples of the cord-and-plug-connected equipment listed under 210.6(C)(6) are through-the-wall heating and air-conditioning units and restaurant deep fat fryers that operate at 480 volts, 3 phase, from a grounded wye system.

The requirements in 210.6 have to be read carefully because 210.6(C) describes the voltage as “volts, nominal, to ground,” whereas 210.6(A), (B), (D), and (E) describe voltage as “volts, nominal, between conductors.” Luminaires listed for and connected to a 480-volt source may be used in applications permitted by 210.6(C), provided the 480-volt system is in fact a grounded wye system that contains a grounded conductor (thus limiting the system “voltage to ground” to the 277-volt level).

**(D) 600 Volts Between Conductors.** Circuits exceeding 277 volts, nominal, to ground and not exceeding 600 volts,

**EXHIBIT 210.4** Examples of luminaires permitted by 210.6(B) and (C) to be connected to branch circuits.

nominal, between conductors shall be permitted to supply the following:

- (1) The auxiliary equipment of electric-discharge lamps mounted in permanently installed luminaires where the luminaires are mounted in accordance with one of the following:
  - a. Not less than a height of 6.7 m (22 ft) on poles or similar structures for the illumination of outdoor areas such as highways, roads, bridges, athletic fields, or parking lots
  - b. Not less than a height of 5.5 m (18 ft) on other structures such as tunnels

The minimum mounting heights required by 210.6(D)(1) are for circuits that exceed 277 volts to ground and do not exceed 600 volts phase to phase. These circuits supply the auxiliary equipment of electric-discharge lamps. Exhibit 210.5 (left) shows the minimum mounting height of 18 ft for luminaires installed in tunnels and similar structures. Exhibit 210.5 (right) illustrates the minimum mounting height of 22 ft for luminaires in outdoor areas such as parking lots.

- (2) Cord-and-plug-connected or permanently connected utilization equipment other than luminaires

The words “other than luminaires” clarify that for the purposes of this requirement, utilization equipment includes only luminaires covered in 200.6(D)(1). For luminaire in-

stallations that are not on poles or in a tunnel, the branch-circuit voltage is limited to 277 volts to ground.

- (3) Luminaires powered from direct-current systems where the luminaire contains a listed, dc-rated ballast that provides isolation between the dc power source and the lamp circuit and protection from electric shock when changing lamps.

Informational Note: See 410.138 for auxiliary equipment limitations.

*Exception No. 1 to (B), (C), and (D): For lampholders of infrared industrial heating appliances as provided in 422.14.*

*Exception No. 2 to (B), (C), and (D): For railway properties as described in 110.19.*

**(E) Over 600 Volts Between Conductors.** Circuits exceeding 600 volts, nominal, between conductors shall be permitted to supply utilization equipment in installations where conditions of maintenance and supervision ensure that only qualified persons service the installation.

## 210.7 Multiple Branch Circuits

Where two or more branch circuits supply devices or equipment on the same yoke, a means to simultaneously disconnect the ungrounded conductors supplying those devices shall be provided at the point at which the branch circuits originate.

**EXHIBIT 210.5** Minimum mounting heights for tunnel and parking lot lighting as required by 210.6(D)(1) for circuits exceeding 277 volts to ground and not exceeding 600 volts between conductors supplying auxiliary equipment of electric-discharge lampholders.

In 210.7, specifying a means to simultaneously disconnect the ungrounded conductors is a safety issue that applies to devices (actually, the single yoke) where more than one branch circuit is involved. Note that this requirement applies to devices or equipment on the same yoke that are supplied by multiple branch circuits. For installations where multi-wire branch circuits supply devices or equipment on a common yoke, see 210.4(B).

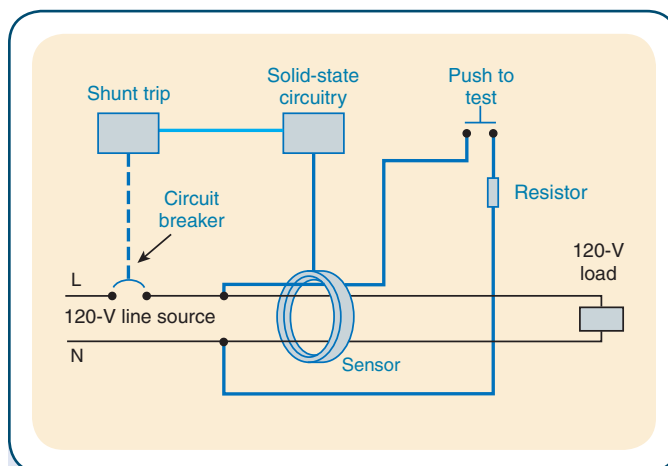

## 210.8 Ground-Fault Circuit-Interrupter Protection for Personnel

Ground-fault circuit-interruption for personnel shall be provided as required in 210.8(A) through (C). The ground-fault circuit-interrupter shall be installed in a readily accessible location.

Section 210.8 is the main rule for application of ground-fault circuit interrupters (GFCIs). Since the introduction of the GFCI in the 1971 *Code*, these devices have proved to their users and to the electrical community that they are worth the added cost during construction or remodeling. Published data from the U.S. Consumer Product Safety Commission show a decreasing trend in the number of electrocutions in the United States since the introduction of GFCI devices. Unfortunately, no statistics are available for the actual number of lives saved or injuries prevented by GFCI devices. However, most safety experts agree that GFCIs are directly responsible for a substantial number of saved lives and prevented injuries.

To ensure proper operation of ground-fault circuit-interrupter devices, the GFCI manufacturer's installation and use instructions specify that they are to be periodically tested, and the prescribed interval is generally every month. The test specified by manufacturers is to operate the test button on the device and verify that all receptacles protected through that GFCI device are de-energized. To facilitate this important ongoing safety check, ground-fault circuit interrupters installed to protect the receptacles covered in 210.8(A) and (B) are required to be readily accessible. See Article 100 for the definition of *readily accessible*.

Exhibit 210.6 shows a typical circuit arrangement of a GFCI. The line conductors are passed through a sensor and are connected to a shunt-trip device. As long as the current in the conductors is equal, the device remains in a closed position. If one of the conductors comes in contact with a grounded object, either directly or through a person's body, some of the current returns by an alternative path, resulting in an unbalanced current. The toroidal coil senses the unbalanced current, and a circuit is established to the shunt-trip mechanism that reacts and opens the circuit. The circuit design does not require the presence of an equipment ground-

**EXHIBIT 210.6** The circuitry and components of a typical GFCI.

ing conductor, which is the reason 406.4(D)(3)(b) permits the use of GFCIs as replacements for receptacles where a grounding means does not exist.

GFCIs operate on currents of 5 mA. The listing standard permits a differential of 4 to 6 mA. At trip levels of 5 mA (the instantaneous current could be much higher), a shock can be felt during the time of the fault. The shock can lead to involuntary reactions that may cause secondary accidents such as falls. GFCIs do not protect persons from shock hazards where contact is between phase and neutral or between phase-to-phase conductors.

A variety of GFCIs are available, including portable and plug-in types and circuit-breaker types, types built into attachment plug caps, and receptacle types. Each type has a test switch so that units can be checked periodically to ensure proper operation. See Exhibits 210.7 and 210.8.

Although 210.8 is the main rule for GFCIs, other specific applications require the use of GFCIs. These additional specific applications are listed in Commentary Table 210.1.

**Informational Note:** See 215.9 for ground-fault circuit-interrupter protection for personnel on feeders.

**(A) Dwelling Units.** All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(A)(1) through (8) shall have ground-fault circuit-interrupter protection for personnel.

(1) Bathrooms

Section 210.8(A)(1) requires that all 125-volt, single-phase, 15- and 20-ampere receptacles in bathrooms have GFCI protection, including receptacles that are integral with luminaires and wall-mounted receptacles adjacent to the basin. There are no exceptions to the bathroom GFCI requirement. For example, if a washing machine is located in the bathroom,

**EXHIBIT 210.7** A GFCI circuit breaker, which provides protection at all outlets supplied by the branch circuit. (Courtesy of Siemens)

the 15- or 20-ampere, 125-volt receptacle that is required to be supplied from the laundry branch circuit must be GFCI protected.

A *bathroom* is defined in Article 100 as “an area including a basin with one or more of the following: a toilet, a urinal, a tub, a shower, a bidet, or similar plumbing fixtures.” The term applies to the entire area, whether or not a separating door, as illustrated in Exhibit 210.9, is present. Section 210.52(D) requires that a receptacle be located on the wall or partition adjacent to each basin location or in the side or face of the basin cabinet. However, if the basins are adjacent and in close proximity, one receptacle outlet, meeting the proximity requirement of 210.52(D) for each basin, can be used to meet the receptacle outlet location requirement, as shown in Exhibit 210.9 (top). Exhibit 210.9 (bottom) also illustrates the requirements of 210.11(C)(3), which provides two acceptable supply circuit arrangements for the bathroom receptacle outlet(s).

- (2) Garages, and also accessory buildings that have a floor located at or below grade level not intended as habitable

**EXHIBIT 210.8** A 15-ampere duplex receptacle with integral GFCI that also protects downstream loads.

rooms and limited to storage areas, work areas, and areas of similar use

The requirement for GFCI receptacles in garages and sheds, as illustrated in Exhibit 210.10, improves safety for persons using portable handheld tools, gardening appliances, lawn mowers, string trimmers, snow blowers, and so on, that might be connected to these receptacles, which are often the closest ones available. GFCI protection is also required in garage areas where auto repair work and general workshop electrical tools are used.

There are no exceptions to the ground-fault circuit-interrupter requirements in 210.8(A)(2), and this ensures that all 125-volt, single-phase, 15- and 20-ampere receptacles installed in garages provide GFCI protection for the user of appliances or other equipment regardless of where the receptacle is located in the garage. Appliance leakage currents permitted by today’s product standards are far less than the operational threshold of a GFCI.

### (3) Outdoors

*Exception to (3): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.*

**COMMENTARY TABLE 210.1** Additional Requirements for the Application of GFCI Protection

Location	Applicable Section(s)
Aircraft hangars	513.12
Audio system equipment	640.10(A)
Boathouses	555.19(B)(1)
Carnivals, circuses, fairs, and similar events	525.23
Commercial garages	511.12
Electric vehicle charging systems	625.22
Electronic equipment, sensitive	647.7(A)
Elevators, escalators, and moving walkways	620.85
Feeders	215.9
Fountains	680.51(A)
Health care facilities	517.20(A), 517.21
High-pressure spray washers	422.49
Hydromassage bathtubs	680.71
Marinas	555.19(B)(1)
Mobile and manufactured homes	550.13(B), 550.13(E), 550.32(E)
Natural and artificially made bodies of water	682.15
Park trailers	552.41(C)
Pools, permanently installed	680.22(A)(1), 680.22(A)(4), 680.22(B)(2), 680.22(B)(3), 680.22(B)(4), 680.23(A)(3)
Pools, storable	680.32
Sensitive electronic equipment	647.7(A)
Signs with fountains	680.57(B)
Signs, mobile or portable	600.10(C)(2)
Recreational vehicles	551.40(C), 551.41(C)
Recreational vehicle parks	551.71
Replacement receptacles	406.4(D)(3)
Temporary installations	590.6

The dwelling unit shown in Exhibit 210.11, which has four outdoor receptacles, illustrates the requirement of 210.8(A)(3). The three receptacles with direct grade-level access must be provided with GFCI protection. The fourth receptacle, located adjacent to the gutter for the roof-mounted snow-melting cable, is not readily accessible and, therefore, is exempt from the GFCI requirements of 210.8(A)(3) because of its dedicated function to supply the deicing equipment. This receptacle is, however, covered by the equipment ground-fault protection requirements of 426.28. See the commentary following 210.52(E) and 406.9(B)(1) regarding the installation of outdoor receptacles in wet and damp locations.

**EXHIBIT 210.9** GFCI-protected receptacles in bathrooms in accordance with 210.8(A)(1).**EXHIBIT 210.10** Examples of receptacles in a garage that are required by 210.8(A)(2) to have GFCI protection.

- (4) Crawl spaces — at or below grade level
- (5) Unfinished basements — for purposes of this section, unfinished basements are defined as portions or areas of the basement not intended as habitable rooms and limited to storage areas, work areas, and the like

**EXHIBIT 210.11** A dwelling unit with three receptacles that are required by 210.8(A)(3) to have GFCI protection, and one that is not required to have GFCI protection because it supplies a roof heating tape and is covered by the requirement of 426.28.

*Exception to (5): A receptacle supplying only a permanently installed fire alarm or burglar alarm system shall not be required to have ground-fault circuit-interrupter protection.*

Informational Note: See 760.41(B) and 760.121(B) for power supply requirements for fire alarm systems.

The receptacles in a work area of a basement, as shown in Exhibit 210.12, must have GFCI protection. Section 210.8(A)(5) does not apply to finished areas in basements, such as sleeping rooms or family rooms, and GFCI protection of receptacles in those areas is not required. The only exception to this requirement is for correlation with the performance requirements covering fire alarm power supplies contained in *NFPA 72®*, *National Fire Alarm and Signaling Code*.

Receptacles installed under the exception to 210.8(A)(5) shall not be considered as meeting the requirements of 210.52(G).

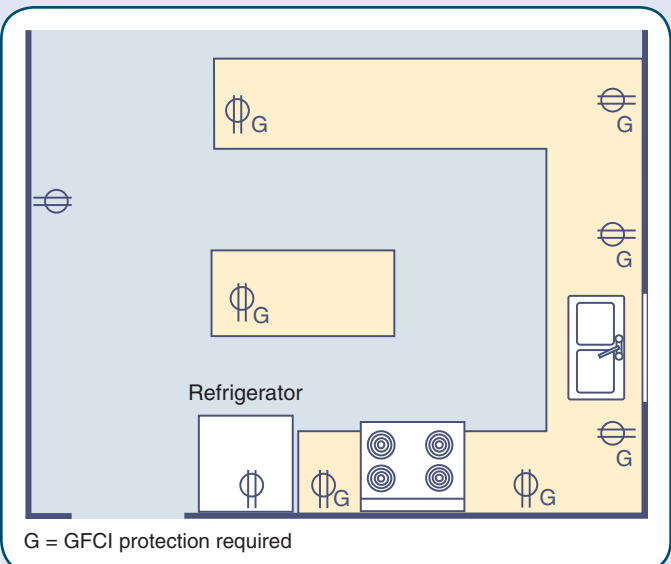

- (6) Kitchens — where the receptacles are installed to serve the countertop surfaces

Many countertop kitchen appliances have only two-wire cords and do not have an equipment grounding conductor. The presence of water and grounded surfaces contributes to a hazardous environment, leading to the requirement in

**EXHIBIT 210.12** A basement floor plan with GFCI-protected receptacles in the work area, in accordance with 210.8(A)(5), and non-GFCI receptacles elsewhere in finished areas.

210.8(A)(6) for GFCI protection around a kitchen sink. See Exhibit 210.13 and Exhibit 210.28. The requirement is intended for receptacles serving the countertop. Receptacles installed for disposals, dishwashers, and trash compactors are not required to be protected by GFCIs. A receptacle(s)

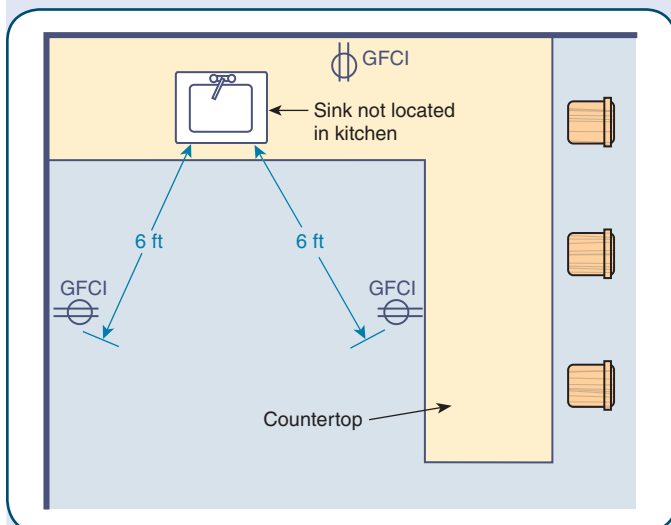

**EXHIBIT 210.13** GFCI-protected receptacles shown in accordance with 210.8(A)(6) to serve countertop surfaces in dwelling unit kitchens.

installed behind a refrigerator is installed to supply that appliance, not the countertop, and is not covered by this GFCI requirement. According to 406.5(E), receptacles installed to serve countertops cannot be installed in the countertop in the face-up position because liquid, dirt, and other foreign material can enter the receptacle.

- (7) **Sinks** — located in areas other than kitchens where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink

Recognizing that sinks in kitchens are not the only location where a ground-fault shock hazard exists, this requirement covers all other sinks in a dwelling. This requirement does not limit the GFCI requirement to only receptacles serving countertop surfaces; rather, it covers all 125-volt, 15- and 20-ampere receptacles that are within 6 ft of any point along the outside edge of the sink. Many appliances used in these locations are ungrounded, and the presence of water and grounded surfaces contributes to a hazardous environment. As illustrated in Exhibit 210.14, any 125-volt, 15- and 20-ampere receptacle installed within 6 ft of a sink located in other than a kitchen is required to be GFCI protected.

**EXHIBIT 210.14** GFCI protection of receptacles located within 6 ft of a sink located in other than the kitchen, in accordance with 210.8(A)(7).

#### (8) Boathouses

**(B) Other Than Dwelling Units.** All 125-volt, single-phase, 15- and 20-ampere receptacles installed in the locations specified in 210.8(B)(1) through (8) shall have ground-fault circuit-interrupter protection for personnel.

#### (1) Bathrooms

If 125-volt, single-phase, 15- and 20-ampere receptacles are provided in the bathroom areas of occupancies other than dwelling units, GFCI-protected receptacles are required. Some motel and hotel bathrooms, like the one shown in Exhibit 210.15, have the basin located outside the door to the room containing the tub, toilet, or another basin. *Bathroom* as defined in Article 100 uses the word “area,” so that the sink shown in Exhibit 210.15 is considered as being in the bathroom and is subject to the GFCI requirements of 210.8(B)(1). If the guest room or guest suite has permanent provisions for cooking, 210.18 requires compliance with all dwelling unit branch-circuit rules. In Exhibit 210.15 the supply circuit requirement of 210.11(C)(3) for the bathroom receptacle outlets is depicted.

**EXHIBIT 210.15** GFCI protection of receptacles in a motel/hotel bathroom where one basin is located outside the door to the rest of the bathroom area, in accordance with 210.8(B)(1).

#### (2) Kitchens

Section 210.8(B)(2) requires all 15- and 20-ampere, 125-volt receptacles in nondwelling-type kitchens to be GFCI protected. This requirement applies to all 15- and 20-ampere, 125-volt kitchen receptacles, whether or not the receptacle serves countertop areas.

Accident data provided from the NIOSH database related to electrical incidents in nondwelling kitchens reveal the presence of many hazards, including poorly maintained electrical apparatus, damaged electrical cords, wet floors, and employees without proper electrical safety training.

Requiring GFCI protection in kitchens located in other than dwelling units protects personnel exposed to conditions that are conducive to electric shock accidents. The definition of kitchen in Article 100 is “an area with a sink and permanent facilities for food preparation and cooking.” A portable cooking appliance (e.g., cord-and-plug-connected microwave oven or hot plate) is not a permanent cooking facility. Kitchens, meeting the Article 100 definition, in restaurants, hotels, schools, churches, dining halls, and similar facilities are examples of the types of kitchens covered by this requirement.

### (3) Rooftops

For rooftops that also have heating, air-conditioning, and refrigeration equipment, see 210.63.

### (4) Outdoors

*Exception No. 1 to (3) and (4): Receptacles that are not readily accessible and are supplied by a branch circuit dedicated to electric snow-melting, deicing, or pipeline and vessel heating equipment shall be permitted to be installed in accordance with 426.28 or 427.22, as applicable.*

*Exception No. 2 to (4): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified personnel are involved, an assured equipment grounding conductor program as specified in 590.6(B)(2) shall be permitted for only those receptacle outlets used to supply equipment that would create a greater hazard if power is interrupted or having a design that is not compatible with GFCI protection.*

Electrocution and electrical shock accident data provided by the U.S. Consumer Product Safety Commission indicate that electric shock accidents occur at locations other than dwelling units and construction sites. Although commercial, institutional, and industrial occupancies are not required to have outdoor receptacle outlets installed for general use, there may be outdoor receptacle outlets installed to meet the requirement of 210.63 or at the discretion of the designer or owner. Other than the limited exclusions covered by the two exceptions to 210.8(B)(4), all 125-volt, single-phase, 15- and 20-ampere receptacles installed outdoors at commercial, institutional, and industrial occupancies are required to be provided with ground-fault circuit-interrupter protection.

### (5) Sinks — where receptacles are installed within 1.8 m (6 ft) of the outside edge of the sink.

This requirement covers receptacles installed near sinks in lunchrooms, janitors’ closets, classrooms, and all other areas that are not covered by the bathroom and kitchen provisions of 210.8(B)(1) and (B)(2). Exhibit 210.16 shows two, single-phase, 125-volt, 15-ampere duplex receptacles installed within 6 ft of a sink that are covered by the GFCI requirement of 210.8(B)(5). The 240-volt receptacle to the right of the duplex receptacles is not subject to the GFCI requirement.

**EXHIBIT 210.16** GFCI protection required for single-phase, 125 volt, 15 ampere rated duplex receptacles installed within 6 ft of a sink.

*Exception No. 1 to (5): In industrial laboratories, receptacles used to supply equipment where removal of power would introduce a greater hazard shall be permitted to be installed without GFCI protection.*

*Exception No. 2 to (5): For receptacles located in patient bed locations of general care or critical care areas of health care facilities other than those covered under 210.8(B)(1), GFCI protection shall not be required.*

- (6) Indoor wet locations
- (7) Locker rooms with associated showering facilities
- (8) Garages, service bays, and similar areas where electrical diagnostic equipment, electrical hand tools, or portable lighting equipment are to be used

**(C) Boat Hoists.** GFCI protection shall be provided for outlets not exceeding 240 volts that supply boat hoists installed in dwelling unit locations.

The proximity of this type of equipment to water and the wet or damp environment inherent to the location in which boat

hoists are used is the reason for this GFCI requirement. Documented cases of electrocutions associated with the use of boat hoists compiled by the U.S. Consumer Product Safety Commission substantiated the need for this requirement. The requirement applies only to dwelling unit locations, and GFCI protection must be provided for boat hoists supplied by 15- or 20-ampere branch circuits rated 240 volts or less. It is important to note that in contrast to the requirements in 210.8(A) and (B), 210.8(C) applies to all outlets supplied from 15- and 20-ampere, 120-volt branch circuits, not just to receptacle outlets. Therefore, both cord-and-plug-connected and hard-wired boat hoists are required to be GFCI protected.

### 210.9 Circuits Derived from Autotransformers

Branch circuits shall not be derived from autotransformers unless the circuit supplied has a grounded conductor that is electrically connected to a grounded conductor of the system supplying the autotransformer.

Exhibits 210.17 through 210.20 illustrate typical applications of autotransformers. In Exhibit 210.17, a 120-volt supply is derived from a 240-volt system. The grounded conductor of the primary system is electrically connected to the grounded conductor of the secondary system.

A buck-boost transformer is classified as an autotransformer. A buck-boost transformer provides a means of raising (boosting) or lowering (bucking) a supply line voltage by a small amount (usually no more than 20 percent). A buck-boost is a transformer with two primary windings (H1-H2 and H3-H4) and two secondary windings (X1-X2 and X3-X4). Its primary and secondary windings are connected so that the electrical characteristics are changed from a transformer that has its primary and secondary windings insulated from each other to one that has primary and second-

**EXHIBIT 210.17** Circuitry for an autotransformer used to derive a 2-wire, 120-volt system for lighting or convenience receptacles from a 240-volt corner-grounded delta system.

**EXHIBIT 210.18** Circuitry for an autotransformer used to derive a 240-volt system for appliances from a 208Y/120-volt source, in accordance with 210.9, Exception No. 1.

Boost (increase)

Buck (decrease)

H = high voltage  
X = low voltage

**EXHIBIT 210.19** Typical single-phase connection diagrams for buck or boost transformers connected as autotransformers to change 240 volts single-phase to 208 volts and vice versa.

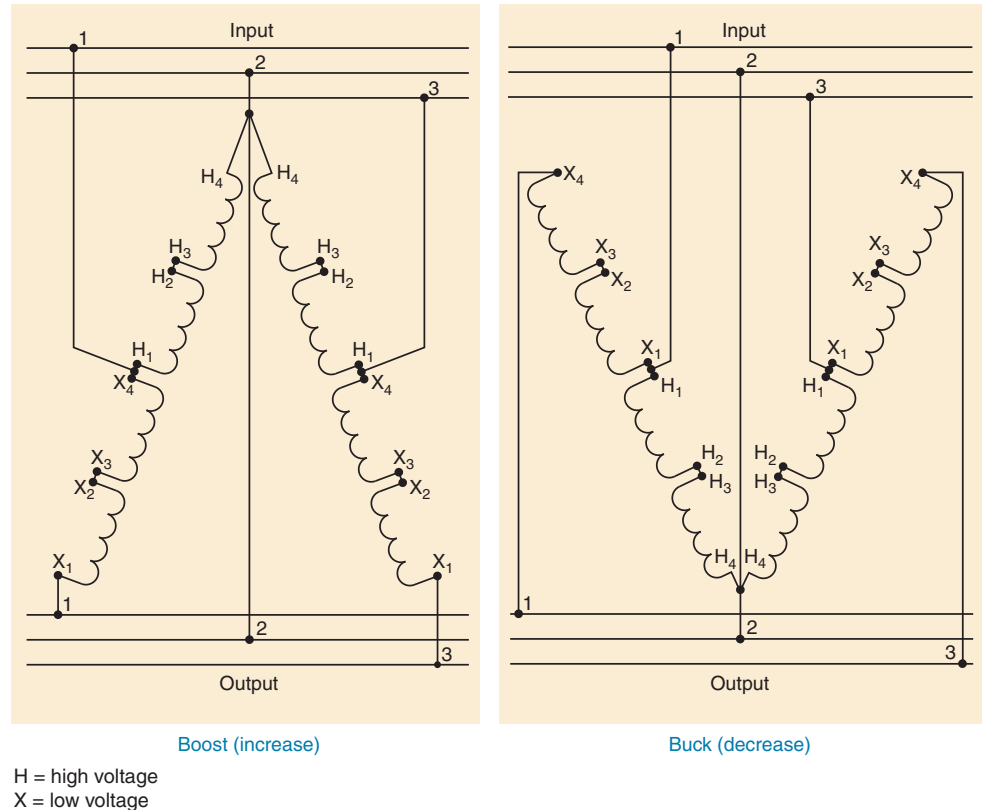

ary windings connected to buck or boost the voltage as an autotransformer, correcting voltage by up to 20 percent.

A single unit is used to boost or buck single-phase voltage, but two or three units are used to boost or buck 3-phase voltage. An autotransformer requires little physical space, is economical, and, above all, is efficient.

One common application of a boost transformer is to derive a single-phase, 240-volt supply system for ranges, air conditioners, heating elements, and motors from a 3-phase, 208Y/120-volt source system. The boosted leg should not be used to supply line-to-neutral loads, because the boosted line-to-neutral voltage will be higher than 120 volts. Another common boost transformer application is to increase a single-phase, 240-volt source to a single-phase, 277-volt supply for lighting systems. One common 3-phase application is to boost 440 volts to 550 volts for power equipment.

**EXHIBIT 210.20** Typical connection diagrams for buck or boost transformers connected in 3-phase open delta as auto-transformers to change 240 volts to 208 volts and vice versa.

Other common applications of a buck transformer include transforming 240 volts to 208 volts for use with 208-volt appliances and converting a 480Y/277-volt source to a 416Y/240-volt supply system.

*Exception No. 1: An autotransformer shall be permitted without the connection to a grounded conductor where transforming from a nominal 208 volts to a nominal 240-volt supply or similarly from 240 volts to 208 volts.*

Exception No. 1 to 210.9 allows an autotransformer (without an electrical connection to a grounded conductor) to extend or add an individual branch circuit in an existing installation where transforming (boosting) 208 volts to 240 volts, as shown in Exhibit 210.18. Exhibits 210.19 and 210.20 illustrate typical single-phase and 3-phase buck and boost transformers connected as autotransformers to change 240 volts to 208 volts and vice versa.

*Exception No. 2: In industrial occupancies, where conditions of maintenance and supervision ensure that only qualified persons service the installation, autotransformers shall be permitted to supply nominal 600-volt loads from nominal 480-volt systems, and 480-volt loads from nominal 600-volt*

*systems, without the connection to a similar grounded conductor.*

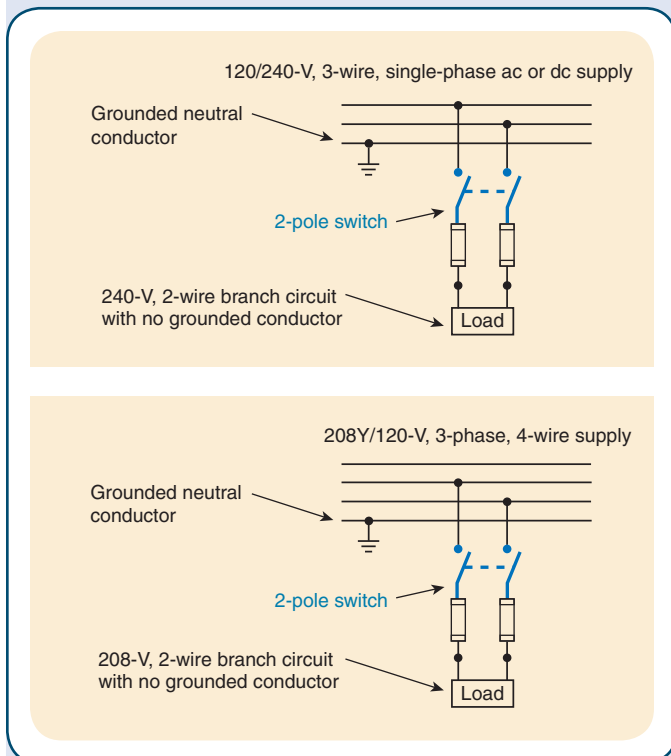

### 210.10 Ungrounded Conductors Tapped from Grounded Systems

Two-wire dc circuits and ac circuits of two or more ungrounded conductors shall be permitted to be tapped from the ungrounded conductors of circuits that have a grounded neutral conductor. Switching devices in each tapped circuit shall have a pole in each ungrounded conductor. All poles of multipole switching devices shall manually switch together where such switching devices also serve as a disconnecting means as required by the following:

- (1) 410.93 for double-pole switched lampholders
- (2) 410.104(B) for electric-discharge lamp auxiliary equipment switching devices
- (3) 422.31(B) for an appliance
- (4) 424.20 for a fixed electric space-heating unit
- (5) 426.51 for electric deicing and snow-melting equipment
- (6) 430.85 for a motor controller
- (7) 430.103 for a motor

Exhibit 210.21 (top) illustrates an ungrounded 2-wire branch circuit tapped from the ungrounded conductors of a dc or

single-phase system to supply a small motor. Exhibit 210.21 (bottom) illustrates a 3-phase, 4-wire wye system. Based on the characteristics of the depicted loads (line-to-line connected) supplied by the tapped circuits, a neutral or grounded conductor is not required to be installed with the ungrounded conductors.

**EXHIBIT 210.21** Branch circuits tapped from ungrounded conductors of multiwire systems.

Circuit breakers or switches that are used as the disconnecting means for a branch circuit must open all poles simultaneously using only the manual operation of the disconnecting means. Therefore, if switches and fuses are used and one fuse blows, or if circuit breakers (two single-pole circuit breakers with a handle tie) are used and one breaker trips, one pole could possibly remain closed. The intention is not to require a common trip of fuses or circuit breakers but rather to disconnect (manually) the ungrounded conductors of the branch circuit with one manual operation. See 240.15(B) for information on the use of identified handle ties with single-pole circuit breakers.

### 210.11 Branch Circuits Required

Branch circuits for lighting and for appliances, including motor-operated appliances, shall be provided to supply the loads calculated in accordance with 220.10. In addition,

branch circuits shall be provided for specific loads not covered by 220.10 where required elsewhere in this *Code* and for dwelling unit loads as specified in 210.11(C).

**(A) Number of Branch Circuits.** The minimum number of branch circuits shall be determined from the total calculated load and the size or rating of the circuits used. In all installations, the number of circuits shall be sufficient to supply the load served. In no case shall the load on any circuit exceed the maximum specified by 220.18.

**(B) Load Evenly Proportioned Among Branch Circuits.** Where the load is calculated on the basis of **volt-amperes per square meter** or **per square foot**, the wiring system up to and including the branch-circuit panelboard(s) shall be provided to serve not less than the calculated load. This load shall be evenly proportioned among multioutlet branch circuits within the panelboard(s). Branch-circuit overcurrent devices and circuits shall be required to be installed only to serve the connected load.

### (C) Dwelling Units.

**(1) Small-Appliance Branch Circuits.** In addition to the number of branch circuits required by other parts of this section, two or more 20-ampere small-appliance branch circuits shall be provided for all receptacle outlets specified by 210.52(B).

**(2) Laundry Branch Circuits.** In addition to the number of branch circuits required by other parts of this section, at least one additional 20-ampere branch circuit shall be provided to supply the laundry receptacle outlet(s) required by 210.52(F). This circuit shall have no other outlets.

**(3) Bathroom Branch Circuits.** In addition to the number of branch circuits required by other parts of this section, at least one 20-ampere branch circuit shall be provided to supply bathroom receptacle outlet(s). Such circuits shall have no other outlets.

*Exception: Where the 20-ampere circuit supplies a single bathroom, outlets for other equipment within the same bathroom shall be permitted to be supplied in accordance with 210.23(A)(1) and (A)(2).*

Informational Note: See Examples D1(a), D1(b), D2(b), and D4(a) in Informative Annex D.

## 210.12 Arc-Fault Circuit-Interrupter Protection

**(A) Dwelling Units.** All 120-volt, single phase, 15- and 20-ampere branch circuits supplying outlets installed in

dwelling unit family rooms, dining rooms, living rooms, parlors, libraries, dens, bedrooms, sunrooms, recreation rooms, closets, hallways, or similar rooms or areas shall be protected by a listed arc-fault circuit interrupter, combination-type, installed to provide protection of the branch circuit.

Informational Note No. 1: For information on types of arc-fault circuit interrupters, see UL 1699-1999, *Standard for Arc-Fault Circuit Interrupters*.

Informational Note No. 2: See 11.6.3(5) of *NFPA 72-2010, National Fire Alarm and Signaling Code*, for information related to secondary power supply requirements for smoke alarms installed in dwelling units.

Informational Note No. 3: See 760.41(B) and 760.121(B) for power-supply requirements for fire alarm systems.

*Exception No. 1: If RMC, IMC, EMT, Type MC, or steel armored Type AC cables meeting the requirements of 250.118 and metal outlet and junction boxes are installed for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install an outlet branch-circuit type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.*

*Exception No. 2: Where a listed metal or nonmetallic conduit or tubing is encased in not less than 50 mm (2 in.) of concrete for the portion of the branch circuit between the branch-circuit overcurrent device and the first outlet, it shall be permitted to install an outlet branch-circuit type AFCI at the first outlet to provide protection for the remaining portion of the branch circuit.*

*Exception No. 3: Where an individual branch circuit to a fire alarm system installed in accordance with 760.41(B) or 760.121(B) is installed in RMC, IMC, EMT, or steel-sheathed cable, Type AC or Type MC, meeting the requirements of 250.118, with metal outlet and junction boxes, AFCI protection shall be permitted to be omitted.*

The definition of arc-fault circuit interrupter in Article 100 explains the safety function of this type of device. The objective is to de-energize the branch circuit when an arc fault is detected.

Arc-fault circuit interrupters are evaluated in UL 1699, *Standard for Arc-Fault Circuit-Interrupters*, using testing methods that create or simulate arcing conditions to determine a product's ability to detect and interrupt arcing faults. These devices are also tested to verify that arc detection is not unduly inhibited by the presence of loads and circuit characteristics that may mask the hazardous arcing condition. In addition, these devices are evaluated to determine resistance to unwanted tripping due to the presence of arcing that occurs in control and utilization equipment under nor-

mal operating conditions or to a loading condition that closely mimics an arcing fault, such as a solid-state electronic ballast or a dimmed load.

UL 1699 is the standard covering arc-fault devices that have a maximum rating of 20 amperes and intended for use in 120-volt ac, 60-Hz circuits. These devices may also have the capability to perform other functions such as overcurrent protection, ground-fault circuit interruption, and surge suppression. UL 1699 currently recognizes five types of arc-fault circuit interrupters: branch/feeder AFCI, combination AFCI, cord AFCI, outlet AFCI, and portable AFCI.

Placement of the device in the circuit and a review of the UL guide information must be considered when complying with 210.12. The *NEC* is clear that the objective is to provide protection of the entire branch circuit. (See Article 100 for the definition of branch circuit.) For instance, a cord AFCI cannot be used to comply with the requirement of 210.12 to protect the entire branch circuit.

To provide the full range of AFCI protection covered in the UL standard for the branch-circuit conductors and at the outlets supplied by the branch circuit, the use of combination-type AFCI devices is required. These devices provide the combined protection required by UL 1699 for branch/feeder and outlet type AFCIs. The product standard requires specific marking on AFCI devices to indicate the type of protection provided. Combination-type AFCIs bear such a marking. Exhibit 210.22 is an example of a circuit breaker that provides combination-type AFCI protection. Exceptions No. 1 and No. 2 to 210.12(A) permit the AFCI device to be located at the first outlet supplied by a branch circuit, provided that the wiring method from the branch-circuit overcurrent protective device to the outlet is rigid metal conduit, intermediate metal conduit, electrical metallic tubing, or steel armored cable, or is listed metal or nonmetallic conduit or tubing that is encased in not less than 2 in. of concrete. These wiring methods afford a higher level of physical protection for branch-circuit conductors. There is no length restriction on the branch-circuit conductors from the branch-circuit overcurrent protective device to the first outlet as long as the conductors are contained within one of the wiring methods identified in Exception No. 1 or the physical protection afforded by encasement in 2 in. of concrete specified in Exception No. 2 is provided for conduit or tubing.

Section 210.12(A) requires that AFCI protection be provided for all 15- and 20-ampere, 120-volt branch circuits that supply outlets (including receptacle, lighting, and other outlets; see definition of outlet in Article 100) located throughout a dwelling unit other than outlets installed in kitchens, bathrooms, unfinished basements, garages, and outdoors. Because circuits are often shared between a bedroom and other areas such as closets and hallways, providing AFCI protection on the complete circuit would comply with 210.12. There is no prohibition against using AFCI pro-

**EXHIBIT 210.22** The required marking indicating the type of AFCI protection afforded by this circuit breaker.

tection on other circuits or locations other than those specified in 210.12(A).

**(B) Branch Circuit Extensions or Modifications — Dwelling Units.** In any of the areas specified in 210.12(A), where branch-circuit wiring is modified, replaced, or extended, the branch circuit shall be protected by one of the following:

- (1) A listed combination-type AFCI located at the origin of the branch circuit
- (2) A listed outlet branch-circuit type AFCI located at the first receptacle outlet of the existing branch circuit

This section provides a definitive requirement on how to implement AFCI protection where work is performed on existing branch-circuit wiring. Some existing wiring systems present challenges to implementing the type of protection required by 210.12(A) because of their age and circuit configuration. To address these potential obstacles to providing some level of AFCI protection for the existing branch circuits, the *Code* provides the option of installing a

combination-type device at the point where the branch circuit originates (as is required for new branch-circuit installations) or of installing an outlet branch-circuit type AFCI at the first receptacle outlet in the branch circuit. Both options require the use of listed AFCI devices. Where the location of the first receptacle outlet in the existing branch circuit cannot be ascertained, installing a new receptacle outlet, and ensuring it is the first one in the branch circuit, is a means to implement the protection required by 210.12(B)(2).

## 210.18 Guest Rooms and Guest Suites

Guest rooms and guest suites that are provided with permanent provisions for cooking shall have branch circuits installed to meet the rules for dwelling units.

This section ensures that the branch circuits and outlets installed in guest rooms and guest suites equipped with permanent provisions for cooking meet all of the requirements for dwelling units contained in Parts I, II, and III of Article 210. The guest suite configuration shown in Exhibit 210.23 triggers the requirement of 210.18 to install the branch circuit wiring in this unit using all of the branch circuit provisions that apply to dwelling units.

**EXHIBIT 210.23** Guest rooms or suites with permanent provisions for cooking in which the installation of branch circuit must follow all of the requirements in Article 210 covering dwelling units.

## II. Branch-Circuit Ratings

### 210.19 Conductors — Minimum Ampacity and Size

#### (A) Branch Circuits Not More Than 600 Volts.

**(1) General.** Branch-circuit conductors shall have an ampacity not less than the maximum load to be served. Where a

branch circuit supplies continuous loads or any combination of continuous and noncontinuous loads, the minimum branch-circuit conductor size, before the application of any adjustment or correction factors, shall have an allowable ampacity not less than the noncontinuous load plus 125 percent of the continuous load.

*Exception: If the assembly, including the overcurrent devices protecting the branch circuit(s), is listed for operation at 100 percent of its rating, the allowable ampacity of the branch circuit conductors shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.*

Conductors of branch circuits rated not more than 600 volts must be able to supply power to loads without overheating. The requirements in 210.19(A)(1) establish minimum size and ampacity requirements to allow that to happen. The requirements for the minimum size of overcurrent protection devices are found in 210.20. An example showing these minimum-size calculations is found in the commentary following 210.20(A), Exception.

Informational Note No. 1: See 310.15 for ampacity ratings of conductors.

Informational Note No. 2: See Part II of Article 430 for minimum rating of motor branch-circuit conductors.

Informational Note No. 3: See 310.15(A)(3) for temperature limitation of conductors.

Informational Note No. 4: Conductors for branch circuits as defined in Article 100, sized to prevent a voltage drop exceeding 3 percent at the farthest outlet of power, heating, and lighting loads, or combinations of such loads, and where the maximum total voltage drop on both feeders and branch circuits to the farthest outlet does not exceed 5 percent, provide reasonable efficiency of operation. See Informational Note No. 2 of 215.2(A)(3) for voltage drop on feeder conductors.

Informational Note No. 4 expresses a warning about improper voltage due to a voltage drop in supply conductors, a significant source of trouble and inefficient operation in electrical equipment. Undervoltage conditions reduce the capability and reliability of motors, lighting sources, heaters, and solid-state equipment. Sample voltage-drop calculations are found in the commentary following 215.2(A)(4), Informational Note No. 3, and following Table 9 in Chapter 9.

**(2) Branch Circuits with More than One Receptacle.** Conductors of branch circuits supplying more than one re-

ceptacle for cord-and-plug-connected portable loads shall have an ampacity of not less than the rating of the branch circuit.

Because the loading of branch-circuit conductors that supply receptacles for cord-and-plug-connected portable loads is unpredictable, the circuit conductors are required to have an ampacity that is not less than the rating of the branch circuit. According to 210.3, the rating of the branch circuit is actually the rating of the overcurrent device.

**(3) Household Ranges and Cooking Appliances.** Branch-circuit conductors supplying household ranges, wall-mounted ovens, counter-mounted cooking units, and other household cooking appliances shall have an ampacity not less than the rating of the branch circuit and not less than the maximum load to be served. For ranges of 8¾ kW or more rating, the minimum branch-circuit rating shall be 40 amperes.

Based on the basic requirement of 110.14(C)(1)(a), the minimum 40-ampere-rated branch circuit requires the use of 8 AWG Type THW copper or 6 AWG, Type XHHW aluminum conductors. See Table 310.15(B)(16) for other applications.

*Exception No. 1: Conductors tapped from a 50-ampere branch circuit supplying electric ranges, wall-mounted electric ovens, and counter-mounted electric cooking units shall have an ampacity of not less than 20 amperes and shall be sufficient for the load to be served. These tap conductors include any conductors that are a part of the leads supplied with the appliance that are smaller than the branch-circuit conductors. The taps shall not be longer than necessary for servicing the appliance.*

Exception No. 1 to 210.19(A)(3) covers factory-installed and field-installed tap conductors. The supply conductors included in a factory-installed pigtail are considered to be tap conductors in applying this exception. As illustrated in Exhibit 210.24, this exception permits a 20-ampere tap conductor from a range, oven, or cooking unit to be connected to a 50-ampere branch circuit if the following four conditions are met:

1. The taps are not longer than necessary to service or permit access to the junction box.
2. The taps to each unit are properly spliced.
3. The junction box is adjacent to each unit.
4. The taps are of sufficient size for the load to be served.

**EXHIBIT 210.24** Tap conductors permitted by 210.19(A)(3), Exception No. 1, sized smaller than the branch-circuit conductors and not longer than necessary for servicing the appliances.

*Exception No. 2:* The neutral conductor of a 3-wire branch circuit supplying a household electric range, a wall-mounted oven, or a counter-mounted cooking unit shall be permitted to be smaller than the ungrounded conductors where the maximum demand of a range of 8<sup>3</sup>/<sub>4</sub>-kW or more rating has been calculated according to Column C of Table 220.55, but such conductor shall have an ampacity of not less than 70 percent of the branch-circuit rating and shall not be smaller than 10 AWG.

Column C of Table 220.55 indicates that the maximum demand for one range (not over 12 kW rating) is 8 kW (8 kW = 8000 volt-amperes; 8000 volt-amperes ÷ 240 volts = 33.3 amperes). In accordance with the termination temperature requirements of 110.14(C)(1)(a), the allowable ampacity of an 8 AWG copper conductor from the 60°C column of Table 310.15(B)(16) is 40 amperes, and it may be used for the range branch circuit. According to this calculation, the neutral of this 3-wire circuit can be smaller than 8 AWG but not smaller than 10 AWG, which has an allowable ampacity of 30 amperes (30 amperes is more than 70 percent of 40 amperes, per Exception No. 2). The maximum demand for the neutral of an 8-kW range circuit seldom exceeds 25 amperes, because the only line-to-

neutral connected loads are lights, clocks, timers, and the heating elements of some ranges when the control is adjusted to the low-heat setting.

**(4) Other Loads.** Branch-circuit conductors that supply loads other than those specified in 210.2 and other than cooking appliances as covered in 210.19(A)(3) shall have an ampacity sufficient for the loads served and shall not be smaller than 14 AWG.

*Exception No. 1:* Tap conductors shall have an ampacity sufficient for the load served. In addition, they shall have an ampacity of not less than 15 for circuits rated less than 40 amperes and not less than 20 for circuits rated at 40 or 50 amperes and only where these tap conductors supply any of the following loads:

- Individual lampholders or luminaires with taps extending not longer than 450 mm (18 in.) beyond any portion of the lampholder or luminaire.
- A luminaire having tap conductors as provided in 410.117.
- Individual outlets, other than receptacle outlets, with taps not over 450 mm (18 in.) long.
- Infrared lamp industrial heating appliances.
- Nonheating leads of deicing and snow-melting cables and mats.

Tap conductors are generally required to have the same ampacity as the branch-circuit overcurrent device. Exception No. 1 to 210.19(A)(4) lists specific applications in items (a) through (e) where the tap conductors are permitted with reduced ampacities. The requirements for the minimum size tap conductors based on the branch-circuit rating are also summarized in Table 210.24.

*Exception No. 2:* Fixture wires and flexible cords shall be permitted to be smaller than 14 AWG as permitted by 240.5.

**(B) Branch Circuits Over 600 Volts.** The ampacity of conductors shall be in accordance with 310.15 and 310.60, as applicable. Branch-circuit conductors over 600 volts shall be sized in accordance with 210.19(B)(1) or (B)(2).

**(1) General.** The ampacity of branch-circuit conductors shall not be less than 125 percent of the designed potential load of utilization equipment that will be operated simultaneously.

**(2) Supervised Installations.** For supervised installations, branch-circuit conductor sizing shall be permitted to be determined by qualified persons under engineering

supervision. Supervised installations are defined as those portions of a facility where both of the following conditions are met:

- (1) Conditions of design and installation are provided under engineering supervision.
- (2) Qualified persons with documented training and experience in over 600-volt systems provide maintenance, monitoring, and servicing of the system.

Branch circuits over 600 volts must be sized at 125 percent of the combined simultaneous load, unless the branch circuits over 600 volts are located at facilities that qualify as supervised installations.

### 210.20 Overcurrent Protection

Branch-circuit conductors and equipment shall be protected by overcurrent protective devices that have a rating or setting that complies with 210.20(A) through (D).

**(A) Continuous and Noncontinuous Loads.** Where a branch circuit supplies continuous loads or any combination of continuous and noncontinuous loads, the rating of the overcurrent device shall not be less than the noncontinuous load plus 125 percent of the continuous load.

An example calculation for a continuous load only is illustrated in Exhibit 210.25.

**EXHIBIT 210.25** A continuous load (store lighting) calculated at 125 percent to determine the ampacity of the conductor and the branch-circuit size.

*Exception:* Where the assembly, including the overcurrent devices protecting the branch circuit(s), is listed for operation at 100 percent of its rating, the ampere rating of the overcurrent device shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.

According to 210.20, an overcurrent device that supplies continuous and noncontinuous loads must have a rating that is not less than the sum of 100 percent of the noncontinuous load plus 125 percent of the continuous load, calculated in accordance with Article 210. Because grounded/neutral conductors are generally not connected to the terminals of an overcurrent protective device, this requirement for sizing conductors subject to continuous loads does not apply. Grounded/neutral conductors are typically connected to a neutral bus or neutral terminal bar located in distribution equipment.

In addition, 210.19(A)(1) requires that the circuit conductors, chosen from the ampacity tables, have an initial ampacity of not less than the sum of 100 percent of the noncontinuous load plus 125 percent of the continuous load, the same as calculated for the overcurrent device.

The rating of the overcurrent device cannot exceed the final ampacity of the circuit conductors after all the derating or correction factors have been applied, such as for temperature or number of conductors.

#### Calculation Example

Determine the minimum-size overcurrent protective device and the minimum conductor size for the following circuit:

- 25 amperes of continuous load
- 60°C overcurrent device terminal rating
- Type THWN conductors
- Four current-carrying copper conductors in a raceway

#### Solution

**STEP 1.** Determine the size of the overcurrent protective device (OCPD). Referring to 210.20(A), 125 percent of 25 amperes is 31.25 amperes. Thus, the minimum standard-size overcurrent device, according to 240.6(A), is 35 amperes.

**STEP 2.** Determine the minimum conductor size. The ampacity of the conductor must not be less than 125 percent of the 25-ampere continuous load, which results in 31.25 amperes. The conductor must have an allowable ampacity of not less than 31.25 amperes before any adjustment or correction factors are applied.

Because of the 60°C rating of the overcurrent device terminal, it is necessary to choose a conductor based on the ampacities in the 60°C column of Table 310.15(B)(16). The calculated load must not exceed the conductor ampacity. Therefore, an 8 AWG conductor with a 60°C allowable ampacity of 40 amperes is the minimum size permitted. Conductors with a higher allowable ampacity based on their insulation temperature rating may be used, but only at a 60°C allowable ampacity.

**STEP 3.** Because there are four current-carrying conductors in the raceway, Table 310.15(B)(3)(a) applies. Calculate the

ampacity of the conductor using the ampacity value calculated above:

$$\text{Conductor ampacity} = \frac{\text{Calculated load}}{\text{Percent adjustment factor from Table 310.15(B)(3)(a)}}$$

$$\frac{25 \text{ amperes}}{0.80} = 31.25 \text{ amperes}$$

The conductor ampacity determined in Step 2 is not the calculated load that is used in this step. It is a calculation that is used to determine a minimum conductor ampacity and circular mil area to ensure sufficient dissipation of heat at the terminals of overcurrent protective devices supplying continuous loads. The calculated load is 25 amperes. The phrase “before the application of any adjustment or correction factors” has the effect of not requiring that the conductor be subjected to a “double-derating” where continuous loads are supplied by a conductor that is also subject to ampacity adjustment, because there are more than three current-carrying conductors in a cable or raceway or is subject to ampacity correction due to the installation being made where the ambient temperature exceeds 86°F.

**(B) Conductor Protection.** Conductors shall be protected in accordance with 240.4. Flexible cords and fixture wires shall be protected in accordance with 240.5.

**(C) Equipment.** The rating or setting of the overcurrent protective device shall not exceed that specified in the applicable articles referenced in Table 240.3 for equipment.

**(D) Outlet Devices.** The rating or setting shall not exceed that specified in 210.21 for outlet devices.

## 210.21 Outlet Devices

Outlet devices shall have an ampere rating that is not less than the load to be served and shall comply with 210.21(A) and (B).

**(A) Lampholders.** Where connected to a branch circuit having a rating in excess of 20 amperes, lampholders shall be of the heavy-duty type. A heavy-duty lampholder shall have a rating of not less than 660 watts if of the admedium type, or not less than 750 watts if of any other type.

The intent of 210.21(A) is to restrict a fluorescent lighting branch-circuit rating to not more than 20 amperes because most lampholders manufactured for use with fluorescent lights have a rating less than that required for heavy-duty lampholders (660 watts for admedium type or 750 watts for all other types).

Branch-circuit conductors for fluorescent electric-discharge lighting are usually connected to ballasts rather than to lampholders, and, by specifying a wattage rating for these lampholders, a limit of 20 amperes is applied to ballast circuits.

Only the admedium-base lampholder is recognized as heavy duty at the rating of 660 watts. Other lampholders are required to have a rating of not less than 750 watts to be recognized as heavy duty. The requirement of 210.21(A) prohibits the use of medium-base screw shell lampholders on branch circuits that are in excess of 20 amperes.

## (B) Receptacles.

**(1) Single Receptacle on an Individual Branch Circuit.** A single receptacle installed on an individual branch circuit shall have an ampere rating not less than that of the branch circuit.

*Exception No. 1: A receptacle installed in accordance with 430.81(B).*

*Exception No. 2: A receptacle installed exclusively for the use of a cord-and-plug-connected arc welder shall be permitted to have an ampere rating not less than the minimum branch-circuit conductor ampacity determined by 630.11(A) for arc welders.*

Informational Note: See the definition of *receptacle* in Article 100.

**(2) Total Cord-and-Plug-Connected Load.** Where connected to a branch circuit supplying two or more receptacles or outlets, a receptacle shall not supply a total cord-and-plug-connected load in excess of the maximum specified in Table 210.21(B)(2).

**TABLE 210.21(B)(2) Maximum Cord-and-Plug-Connected Load to Receptacle**

Circuit Rating (Amperes)	Receptacle Rating (Amperes)	Maximum Load (Amperes)
15 or 20	15	12
20	20	16
30	30	24

**(3) Receptacle Ratings.** Where connected to a branch circuit supplying two or more receptacles or outlets, receptacle ratings shall conform to the values listed in Table 210.21(B)(3), or, where rated higher than 50 amperes, the receptacle rating shall not be less than the branch-circuit rating.

*Exception No. 1: Receptacles for one or more cord-and-plug-connected arc welders shall be permitted to have*

**TABLE 210.21(B)(3) Receptacle Ratings for Various Size Circuits**

Circuit Rating (Amperes)	Receptacle Rating (Amperes)
15	Not over 15
20	15 or 20
30	30
40	40 or 50
50	50

ampere ratings not less than the minimum branch-circuit conductor ampacity permitted by 630.11(A) or (B), as applicable for arc welders.

*Exception No. 2: The ampere rating of a receptacle installed for electric discharge lighting shall be permitted to be based on 410.62(C).*

A single receptacle installed on an individual branch circuit must have an ampere rating not less than that of the branch circuit. For example, a single receptacle on a 20-ampere individual branch circuit must be rated at 20 amperes in accordance with 210.21(B)(1); however, two or more 15-ampere single receptacles or a 15-ampere duplex receptacle are permitted on a 20-ampere branch circuit in accordance with 210.21(B)(3). This requirement does not apply to specific types of cord-and-plug-connected arc welders.

**(4) Range Receptacle Rating.** The ampere rating of a range receptacle shall be permitted to be based on a single range demand load as specified in Table 220.55.

## 210.23 Permissible Loads

In no case shall the load exceed the branch-circuit ampere rating. An individual branch circuit shall be permitted to supply any load for which it is rated. A branch circuit supplying two or more outlets or receptacles shall supply only the loads specified according to its size as specified in 210.23(A) through (D) and as summarized in 210.24 and Table 210.24.

According to 210.23, an individual (single-outlet) branch circuit can supply any load within its rating.

**(A) 15- and 20-Ampere Branch Circuits.** A 15- or 20-ampere branch circuit shall be permitted to supply lighting units or other utilization equipment, or a combination of both, and shall comply with 210.23(A)(1) and (A)(2).

*Exception: The small-appliance branch circuits, laundry branch circuits, and bathroom branch circuits required in a dwelling unit(s) by 210.11(C)(1), (C)(2), and (C)(3) shall supply only the receptacle outlets specified in that section.*

**(1) Cord-and-Plug-Connected Equipment Not Fastened in Place.** The rating of any one cord-and-plug-connected utilization equipment not fastened in place shall not exceed 80 percent of the branch-circuit ampere rating.

**(2) Utilization Equipment Fastened in Place.** The total rating of utilization equipment fastened in place, other than luminaires, shall not exceed 50 percent of the branch-circuit ampere rating where lighting units, cord-and-plug-connected utilization equipment not fastened in place, or both, are also supplied.

**TABLE 210.24 Summary of Branch-Circuit Requirements**

Circuit Rating	15 A	20 A	30 A	40 A	50 A
Conductors (min. size):					
Circuit wires <sup>1</sup>	14	12	10	8	6

<b>Maximum Load</b>	<b>15 A</b>	<b>20 A</b>	<b>30 A</b>	<b>40 A</b>	<b>50 A</b>
Permissible load	See 210.23(A)	See 210.23(A)	See 210.23(B)	See 210.23(C)	See 210.23(C)

<sup>1</sup>These gauges are for copper conductors.

<sup>2</sup>For receptacle rating of cord-connected electric-discharge luminaires, see 410.62(C).

Section 210.23(A)(2) permits a 15- or 20-ampere branch circuit supplying lighting outlets to also supply utilization equipment fastened in place, such as appliances or an air conditioner. Under the conditions specified in this requirement, the utilization equipment load must not exceed 50 percent of the branch-circuit ampere rating (7.5 amperes on a 15-ampere circuit and 10 amperes on a 20-ampere circuit). However, according to 210.52(B), such fastened-in-place equipment is not permitted on the small-appliance branch circuits required in a kitchen, dining room, and so on. The requirement in 210.23(A)(1) clarifies that only cord-and-plug-connected utilization equipment that is not fastened in place can have a rating of up to 80 percent of the branch-circuit rating where the circuit also supplies other loads. Equipment that is fastened in place, whether direct wired or cord and plug connected (waste disposers and dishwashers, for example), is covered by the 50-percent requirement in 210.23(A)(2). The requirements of 210.23(A)(2) do not apply to a branch circuit that supplies only fastened-in-place utilization equipment, and where that is the case the entire rating of the branch circuit can be applied to the utilization equipment. For example, a 20-ampere branch circuit dedicated to supplying a waste disposer and a dishwasher is not restricted to either one of the appliances not exceeding 50 percent (10 amperes) of the branch-circuit rating as long as the combined load of the two appliances does not exceed 20 amperes.

**(B) 30-Ampere Branch Circuits.** A 30-ampere branch circuit shall be permitted to supply fixed lighting units with heavy-duty lampholders in other than a dwelling unit(s) or utilization equipment in any occupancy. A rating of any one cord-and-plug-connected utilization equipment shall not exceed 80 percent of the branch-circuit ampere rating.

**(C) 40- and 50-Ampere Branch Circuits.** A 40- or 50-ampere branch circuit shall be permitted to supply cooking appliances that are fastened in place in any occupancy. In other than dwelling units, such circuits shall be permitted to supply fixed lighting units with heavy-duty lampholders, infrared heating units, or other utilization equipment.

**(D) Branch Circuits Larger Than 50 Amperes.** Branch circuits larger than 50 amperes shall supply only nonlighting outlet loads.

See the commentary following 210.3, Exception, regarding multioutlet branch circuits greater than 50 amperes that are permitted to supply nonlighting outlet loads at industrial premises.

## 210.24 Branch-Circuit Requirements — Summary

The requirements for circuits that have two or more outlets or receptacles, other than the receptacle circuits of 210.11(C)(1), (C)(2), and (C)(3), are summarized in Table 210.24. This table provides only a summary of minimum requirements. See 210.19, 210.20, and 210.21 for the specific requirements applying to branch circuits.

Table 210.24 summarizes the branch-circuit requirements of conductors, overcurrent protection, outlet devices, maximum load, and permissible load where two or more outlets are supplied.

If the branch circuit serves a fixture load and supplies two or more fixture outlets, 210.23 requires the branch circuit to have a specific ampere rating that is based on the rating of the overcurrent device, as stated in 210.3. Thus, if the circuit breaker that protects the branch circuit is rated 20 amperes, the conductors supplying the circuit must have an ampacity not less than 20 amperes.

In accordance with the Article 100 definition of ampacity, the ampacity is determined after all derating (adjustment and correction) factors, such as those in 310.15(B)(3)(a), have been applied. If seven to nine current-carrying conductors are installed in one conduit, a 12 AWG, Type THHN copper conductor [30 amperes, per Table 310.15(B)(16)] adjusted to 70 percent, per Table 310.15(B)(3)(a), has an allowable ampacity of 21 amperes and is suitable for a load of 20 amperes. Thus, this conductor is acceptable for use on the 20-ampere multioutlet branch circuit.

## 210.25 Branch Circuits in Buildings with More Than One Occupancy

**(A) Dwelling Unit Branch Circuits.** Branch circuits in each dwelling unit shall supply only loads within that dwelling unit or loads associated only with that dwelling unit.

**(B) Common Area Branch Circuits.** Branch circuits installed for the purpose of lighting, central alarm, signal, communications, or other purposes for public or common areas of a two-family dwelling, a multifamily dwelling, or a multi-occupancy building shall not be supplied from equipment that supplies an individual dwelling unit or tenant space.

Not only does 210.25 prohibit branch circuits from feeding more than one dwelling unit, it also prohibits the sharing of systems, equipment, or common lighting if that equipment is fed from any of the dwelling units. In addition, common area circuits in occupancies other than dwelling units are

subject to this requirement, and “house load” branch circuits must be supplied from equipment that does not directly supply branch circuits for an individual occupancy or tenant space. The systems, equipment, and lighting for public or common areas are required to be supplied from a separate “house load” panelboard. This requirement permits access to the branch-circuit disconnecting means without the need to enter the space of any tenants. The requirement also prevents a tenant from turning off important circuits that may affect other tenants.

### III. Required Outlets

#### 210.50 General

Receptacle outlets shall be installed as specified in 210.52 through 210.63.

**(A) Cord Pendants.** A cord connector that is supplied by a permanently connected cord pendant shall be considered a receptacle outlet.

**(B) Cord Connections.** A receptacle outlet shall be installed wherever flexible cords with attachment plugs are used. Where flexible cords are permitted to be permanently connected, receptacles shall be permitted to be omitted for such cords.

Flexible cords are permitted to be permanently connected to boxes or fittings where specifically permitted by the *Code*. However, plugging a cord into a lampholder by inserting a screw-plug adapter is not permitted, because 410.90 requires lampholders of the screw shell type to be installed for use as lampholders only.

**(C) Appliance Receptacle Outlets.** Appliance receptacle outlets installed in a dwelling unit for specific appliances, such as laundry equipment, shall be installed within 1.8 m (6 ft) of the intended location of the appliance.

See 210.52(F) and 210.11(C)(2) for requirements regarding laundry receptacle outlets and branch circuits.

#### 210.52 Dwelling Unit Receptacle Outlets

This section provides requirements for 125-volt, 15- and 20-ampere receptacle outlets. The receptacles required by this section shall be in addition to any receptacle that is:

- (1) Part of a luminaire or appliance, or
- (2) Controlled by a wall switch in accordance with 210.70(A)(1), Exception No. 1, or

- (3) Located within cabinets or cupboards, or
- (4) Located more than 1.7 m (5½ ft) above the floor

Permanently installed electric baseboard heaters equipped with factory-installed receptacle outlets or outlets provided as a separate assembly by the manufacturer shall be permitted as the required outlet or outlets for the wall space utilized by such permanently installed heaters. Such receptacle outlets shall not be connected to the heater circuits.

Informational Note: Listed baseboard heaters include instructions that may not permit their installation below receptacle outlets.

The requirements of 210.52 apply to dwelling unit receptacles that are rated 125 volts and 15 or 20 amperes and that are not part of a luminaire or an appliance. These receptacles are normally used to supply lighting and general-purpose electrical equipment and are in addition to the ones that are 5½ ft above the floor and within cupboards and cabinets. An outlet containing a duplex receptacle and wired so that only one of the receptacles is controlled by a wall can be used to meet the receptacle outlet spacing requirement. However, if both halves are controlled by a wall switch(es), an additional unswitched receptacle has to be installed to meet the receptacle outlet spacing requirement. An outlet where both halves of the duplex receptacle are controlled by a wall switch may result in the occupant using an extension cord, run from an outlet or device that is not controlled by a switch, to supply appliances or equipment that require continuous power, such as an electric clock.

According to listing requirements [see 110.3(B)], permanent electric baseboard heaters may not be located beneath wall receptacles. If the receptacle is part of the heater, appliance or lamp cords are less apt to be exposed to the heating elements, as might occur should the cords fall into convector slots. Many electric baseboard heaters are of the low-density type and are longer than 12 ft. To meet the spacing requirements of 210.52(A)(1), the required receptacle may be located as a part of the heater unit, as shown in Exhibit 210.26.

**(A) General Provisions.** In every kitchen, family room, dining room, living room, parlor, library, den, sunroom, bedroom, recreation room, or similar room or area of dwelling units, receptacle outlets shall be installed in accordance with the general provisions specified in 210.52(A)(1) through (A)(3).

**(1) Spacing.** Receptacles shall be installed such that no point measured horizontally along the floor line of any wall space is more than 1.8 m (6 ft) from a receptacle outlet.

**EXHIBIT 210.26** Permanent electric baseboard heater equipped with a receptacle outlet to meet the spacing requirements of 210.52(A).

This rule provides for receptacle outlets to be installed so that an appliance or lamp with a flexible cord attached may be placed anywhere in the room near a wall and be within 6 ft of a receptacle, minimizing the need for occupants to use extension cords. Although not an enforceable requirement, receptacles may be placed equal distances apart where there is no specific room layout for the general use of electrical equipment. Section 210.52(A)(1) does not prohibit a receptacle layout designed for intended utilization equipment or practical room use. For example, receptacles in a living room, family room, or den that are intended to serve home entertainment equipment or home office equipment may be placed in corners, may be grouped, or may be placed in a convenient location. Receptacles that are intended for window-type holiday lighting may be placed under windows. Even if more receptacles than the minimum required are installed in a room, no point in any wall space is permitted to be more than 6 ft from a receptacle.

**(2) Wall Space.** As used in this section, a wall space shall include the following:

- (1) Any space 600 mm (2 ft) or more in width (including space measured around corners) and unbroken along the floor line by doorways and similar openings, fireplaces, and fixed cabinets
- (2) The space occupied by fixed panels in exterior walls, excluding sliding panels
- (3) The space afforded by fixed room dividers, such as free-standing bar-type counters or railings

A wall space is a wall unbroken along the floor line by doorways, fireplaces, archways, and similar openings and may

include two or more walls of a room (around corners), as illustrated in Exhibit 210.27.

**EXHIBIT 210.27** Typical room plan view of the location of dwelling unit receptacles meeting the requirements of 210.52(A).

Fixed room dividers, such as bar-type counters and railings, are required to be included in the 6-ft measurement. Fixed panels in exterior walls are counted as wall space, and a floor-type receptacle close to the wall can be used to meet the required spacing. Isolated, individual wall spaces 2 ft or more in width, which are often used for small pieces of furniture on which a lamp or an appliance may be placed, are required to have a receptacle outlet to preclude the use of an extension cord to supply equipment in such an isolated space.

The word *usable* does not appear at all in 210.52(A)(2) as a condition for determining compliance with the receptacle-spacing requirements. As an example, to correctly determine the dimension of the wall line in a room, the wall space behind the swing of a door is included in the measurement. This does not mean that the receptacle outlet has to be located in that space, only that the space is included in the wall-line measurement.

**(3) Floor Receptacles.** Receptacle outlets in floors shall not be counted as part of the required number of receptacle outlets unless located within 450 mm (18 in.) of the wall.

**(4) Countertop Receptacles.** Receptacles installed for countertop surfaces as specified in 210.52(C) shall not be considered as the receptacles required by 210.52(A).

Because of the need to provide a sufficient number of receptacles for the appliances used at the kitchen counter area, receptacle outlets installed to serve kitchen or dining area counters cannot also be used as the required receptacle outlet for an adjacent wall space that is subject to the requirements of 210.52(A)(1) and (A)(2). The receptacle outlets required by 210.52(C) are considered to be the minimum number needed to meet the countertop appliance needs in today's dwelling units.

### (B) Small Appliances.

**(1) Receptacle Outlets Served.** In the kitchen, pantry, breakfast room, dining room, or similar area of a dwelling unit, the two or more 20-ampere small-appliance branch circuits required by 210.11(C)(1) shall serve all wall and floor receptacle outlets covered by 210.52(A), all countertop outlets covered by 210.52(C), and receptacle outlets for refrigeration equipment.

Section 210.52(B) requires a minimum of two 20-ampere circuits for all receptacle outlets for small-appliance loads, including refrigeration equipment, in the kitchen/dining areas of a dwelling unit. The limited exceptions to 210.52(B)(2) keeps to a minimum loads for specific equipment so that the majority of the circuit capacity is dedicated to supplying cord-and-plug-connected portable appliance loads. Connecting fastened-in-place appliances such as waste disposers or dishwashers to these circuits reduces the capacity to supply the typical higher wattage portable appliances used at a kitchen counter, such as toasters, coffee makers, skillets, mixers, and the like. The Code restricts the loads supplied by these receptacle circuits because the number of cord-and-plug-connected portable appliances used by occupants is generally undetermined.

No restriction is placed on the number of outlets connected to a general-lighting or small-appliance branch circuit. The minimum number of receptacle outlets in a room is determined by 210.52(A) based on the room perimeter and on 210.52(C) for counter spaces. Installing more than the required minimum number of receptacle outlets can also help reduce the need for extension cords and cords lying across counters.

Exhibit 210.28 illustrates the application of the requirements of 210.52(B)(1), (B)(2), and (B)(3). The small-appliance branch circuits illustrated in Exhibit 210.28 are not permitted to serve any other outlets, such as might be connected to exhaust hoods or fans, disposals, or dishwashers. The countertop receptacles are also required to be supplied by these two circuits if only the minimum of two circuits is provided for that dwelling. Only the counter area is required to be supplied by both of the small-appliance branch circuits. The wall receptacle outlets in the kitchen and dining room are per-

mitted to be supplied by one or both of the circuits, as shown in the two diagrams in Exhibit 210.28.

**EXHIBIT 210.28** Small-appliance branch circuits as required by 210.52(B)(1), (B)(2), and (B)(3) for all receptacle outlets in the kitchen (including refrigerator), pantry, and dining room.

*Exception No. 1: In addition to the required receptacles specified by 210.52, switched receptacles supplied from a general-purpose branch circuit as defined in 210.70(A)(1), Exception No. 1, shall be permitted.*

Exception No. 1 to 210.52(B)(1) permits switched receptacles supplied from general-purpose 15-ampere branch circuits to be located in kitchens, pantries, breakfast rooms, and similar areas. See 210.70(A) and Exhibit 210.28 for details.

*Exception No. 2: The receptacle outlet for refrigeration equipment shall be permitted to be supplied from an individual branch circuit rated 15 amperes or greater.*

Exception No. 2 to 210.52(B)(1) allows a choice for refrigeration equipment receptacle outlets located in a kitchen or similar area. An individual 15-ampere or larger branch circuit may serve this equipment, or it may be included in the 20-ampere small-appliance branch circuit. Refrigeration equipment is also exempt from the GFCI requirements of 210.8 where the receptacle outlet for the refrigerator is located so that it cannot be used to serve countertop surfaces as shown in Exhibit 210.28.

**(2) No Other Outlets.** The two or more small-appliance branch circuits specified in 210.52(B)(1) shall have no other outlets.

*Exception No. 1: A receptacle installed solely for the electrical supply to and support of an electric clock in any of the rooms specified in 210.52(B)(1).*

*Exception No. 2: Receptacles installed to provide power for supplemental equipment and lighting on gas-fired ranges, ovens, or counter-mounted cooking units.*

Because of the comparatively small load associated with ignition controls and other electronics, Exception No. 2 to 210.52(B)(2) allows gas-fired appliances to be supplied by a receptacle connected to one of the small-appliance branch circuits. See Exhibit 210.28 for an illustration.

**(3) Kitchen Receptacle Requirements.** Receptacles installed in a kitchen to serve countertop surfaces shall be supplied by not fewer than two small-appliance branch circuits, either or both of which shall also be permitted to supply receptacle outlets in the same kitchen and in other rooms specified in 210.52(B)(1). Additional small-appliance branch circuits shall be permitted to supply receptacle outlets in the kitchen and other rooms specified in 210.52(B)(1). No small-appliance branch circuit shall serve more than one kitchen.

In most dwellings the countertop receptacle outlets supply more of the portable cooking appliances than the wall recep-

tacles in the kitchen and dining areas, hence the requirement for the counter areas to be supplied by no fewer than two small-appliance branch circuits. The *Code* does not specify that both circuits be installed to serve the receptacle outlet(s) at each separate counter area in a kitchen, but rather that the total counter area of a kitchen must be supplied by no fewer than two circuits, and the arrangement of these circuits is determined by the designer or installer.

For example, a single receptacle outlet on a kitchen island is not required to be supplied by both of the small-appliance circuits serving the counter area. To provide efficient distribution of the small-appliance load, the number of receptacles connected to each small-appliance circuit should be carefully analyzed. The concept of evenly proportioning the load as specified in 210.11(A) (for loads calculated on the basis of volt-amperes per square foot) can be used as a best practice in distributing the number of receptacle outlets to be supplied by each of the small-appliance branch circuits. Where additional small-appliance branch circuits are installed, they are subject to all the requirements that apply to the minimum two required circuits.

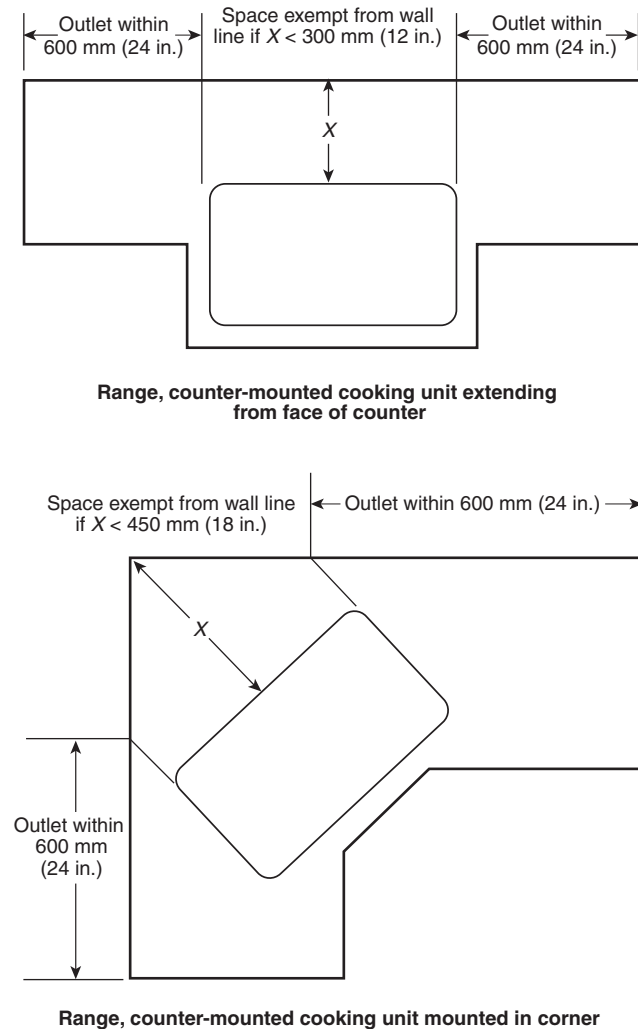

The two circuits that supply the countertop receptacle outlets may also supply receptacle outlets in the pantry, dining room, and breakfast room, as well as an electric clock receptacle and electric loads associated with gas-fired appliances, but these circuits are to supply no other outlets/loads. See 210.8(A)(6) for the GFCI requirements that apply to receptacles serving kitchen counters.

**(C) Countertops.** In kitchens, pantries, breakfast rooms, dining rooms, and similar areas of dwelling units, receptacle outlets for countertop spaces shall be installed in accordance with 210.52(C)(1) through (C)(5).

**(1) Wall Countertop Spaces.** A receptacle outlet shall be installed at each wall countertop space that is 300 mm (12 in.) or wider. Receptacle outlets shall be installed so that no point along the wall line is more than 600 mm (24 in.) measured horizontally from a receptacle outlet in that space.

*Exception: Receptacle outlets shall not be required on a wall directly behind a range, counter-mounted cooking unit, or sink in the installation described in Figure 210.52(C)(1).*

This exception and the associated figure [Figure 210.52(C)(1)] define the wall space behind a sink, range, or counter-mounted cooking unit that is not required to be provided with a receptacle outlet. Figure 210.52(C)(1) also shows where the edge of a sink, range, or counter-mounted cooking unit is considered to be on the wall behind or to the side of

**FIGURE 210.52(C)(1) Determination of Area Behind a Range, or Counter-Mounted Cooking Unit or Sink.**

the sink, range, or counter-mounted cooking unit. Using these benchmarks, compliance with the wall counter receptacle outlet spacing required by 210.52(C)(1) can be determined. Where the space behind a sink, range, or counter-mounted cooking unit is 12 in. or more or 18 in. or more (depending on the counter configuration), the space behind the sink, range, or counter-mounted cooking unit must be included in measuring the wall counter space. Receptacle outlets are not prohibited from being installed in this space.

**(2) Island Countertop Spaces.** At least one receptacle shall be installed at each island countertop space with a long dimension of 600 mm (24 in.) or greater and a short dimension of 300 mm (12 in.) or greater.

**(3) Peninsular Countertop Spaces.** At least one receptacle outlet shall be installed at each peninsular countertop space with a long dimension of 600 mm (24 in.) or greater and a short dimension of 300 mm (12 in.) or greater. A peninsular countertop is measured from the connecting edge.

**(4) Separate Spaces.** Countertop spaces separated by rangetops, refrigerators, or sinks shall be considered as separate countertop spaces in applying the requirements of 210.52(C)(1). If a range, counter-mounted cooking unit, or sink is installed in an island or peninsular countertop and the depth of the countertop behind the range, counter-mounted cooking unit, or sink is less than 300 mm (12 in.), the range, counter-mounted cooking unit, or sink shall be considered to divide the countertop space into two separate countertop spaces. Each separate countertop space shall comply with the applicable requirements in 210.52(C).

Wall, island, and peninsular countertops are subject to this requirement. The general receptacle outlet requirement for qualifying island and peninsula countertop spaces in 210.52(C)(2) and (C)(3) calls for one receptacle outlet regardless of how large the countertop space is. However, if the island or peninsula countertop is separated into two spaces according to this section and each space meets the minimum dimension criteria in 210.52(C)(2) and (C)(3), a minimum of two receptacle outlets is required for the island or peninsular countertop space.

**(5) Receptacle Outlet Location.** Receptacle outlets shall be located on or above, but not more than 500 mm (20 in.) above, the countertop. Receptacle outlet assemblies listed for the application shall be permitted to be installed in countertops. Receptacle outlets rendered not readily accessible by appliances fastened in place, appliance garages, sinks, or rangetops as covered in 210.52(C)(1), Exception, or appliances occupying dedicated space shall not be considered as these required outlets.

**Informational Note:** See 406.5(E) for requirements for installation of receptacles in countertops.

*Exception to (5): To comply with the conditions specified in (1) or (2), receptacle outlets shall be permitted to be mounted not more than 300 mm (12 in.) below the countertop. Receptacles mounted below a countertop in accordance with this exception shall not be located where the countertop extends more than 150 mm (6 in.) beyond its support base.*

- (1) Construction for the physically impaired
- (2) On island and peninsular countertops where the countertop is flat across its entire surface (no backsplashes,

*dividers, etc.) and there are no means to mount a receptacle within 500 mm (20 in.) above the countertop, such as an overhead cabinet*

Dwelling unit receptacles that serve countertop spaces in kitchens, dining areas, and similar rooms, as illustrated in Exhibit 210.29, are required to be installed as follows:

1. In each wall space wider than 12 in. and spaced so that no point along the wall line is more than 24 in. from a receptacle
2. Not more than 20 in. above the countertop [According to 406.5(E), receptacles cannot be installed in a face-up position. Receptacles installed in a face-up position in a countertop could collect crumbs, liquids, and other debris, resulting in a potential fire or shock hazard.]
3. At each countertop island and peninsular countertop with a short dimension of at least 12 in. and a long dimension of at least 24 in. (The measurement of a peninsular-type countertop is from the edge connecting to the nonpeninsular counter.)
4. Accessible for use and not blocked by appliances occupying dedicated space or fastened in place

**EXHIBIT 210.29** Dwelling unit receptacles serving countertop spaces in a kitchen and arranged in accordance with 210.52(C).

5. Fed from two or more of the required 20-ampere small-appliance branch circuits and GFCI protected according to 210.8(A)(6)

The maximum permitted height (20 in.) for a receptacle outlet serving a countertop is based on the standard dimension measured from the countertop to the bottom of the cabinets located above the countertop. This provision allows multioutlet assemblies installed on the bottom of the upper cabinets to be used as the required countertop receptacle outlet(s).

**(D) Bathrooms.** In dwelling units, at least one receptacle outlet shall be installed in bathrooms within 900 mm (3 ft) of the outside edge of each basin. The receptacle outlet shall be located on a wall or partition that is adjacent to the basin or basin countertop, located on the countertop, or installed on the side or face of the basin cabinet not more than 300 mm (12 in.) below the countertop. Receptacle outlet assemblies listed for the application shall be permitted to be installed in the countertop.

Section 210.52(D) requires one wall receptacle in each bathroom of a dwelling unit to be installed adjacent to (within 36 in. of) the basin. An alternative location for the required receptacle outlet is on the side or face of the basin cabinet. Different in application from the exception to 210.52(C)(5), the permission to install a receptacle outlet in the side or face of the basin cabinet is not contingent on the adjacent wall location being unfeasible or inaccessible to a handicapped person. Like the kitchen counter rule, the outlet must be located so that the receptacle(s) is not more than 12 in. below the basin countertop.

This receptacle is required in addition to any receptacle that may be part of any luminaire or medicine cabinet. If there is more than one basin, a receptacle outlet is required adjacent to each basin location. If the basins are in close proximity, one receptacle outlet installed between the two basins can be used to satisfy this requirement. See 406.9(C), which prohibits installation of a receptacle over a bathtub or inside a shower stall. See Exhibit 210.9 for a sample electrical layout of a bathroom.

Section 210.11(C)(3) requires that receptacle outlets be supplied from a 20-ampere branch circuit with no other outlets. However, this circuit is permitted to supply the required receptacles in more than one bathroom. If the circuit supplies the required receptacle outlet in only one bathroom, it is allowed to also supply lighting and an exhaust fan in that bathroom, provided the lighting and fan load does not exceed that permitted by 210.23(A)(2). This receptacle is also required to be GFCI protected in accordance with 210.8(A)(1).

Informational Note: See 406.5(E) for requirements for installation of receptacles in countertops.

**(E) Outdoor Outlets.** Outdoor receptacle outlets shall be installed in accordance with (E)(1) through (E)(3). [See 210.8(A)(3).]

Outdoor receptacles must be installed so that the receptacle faceplate rests securely on the supporting surface to prevent moisture from entering the enclosure. On uneven surfaces, such as brick, stone, or stucco, it may be necessary to close openings with caulking compound or mastic. See 406.9 for further information on receptacles installed in damp or wet locations.

**(1) One-Family and Two-Family Dwellings.** For a one-family dwelling and each unit of a two-family dwelling that is at grade level, at least one receptacle outlet accessible while standing at grade level and located not more than 2.0 m (6½ ft) above grade shall be installed at the front and back of the dwelling.

The rule for one- and two-family dwellings requires two outdoor receptacle outlets for each dwelling unit. One receptacle outlet is required at the front of each dwelling, and one is required at the back of each dwelling, as shown in Exhibit 210.30. For one- and two-family dwellings, the phrase “accessible at grade level” clearly requires that the two required receptacle outlets are to be available to a person standing on the ground (at grade level). Where outdoor heating, air-conditioning, or refrigeration (HACR) equipment is located at grade level, the receptacle outlets required by this section can be used to comply with the receptacle outlet requirement of 210.63, provided that at least one of the outlets is located

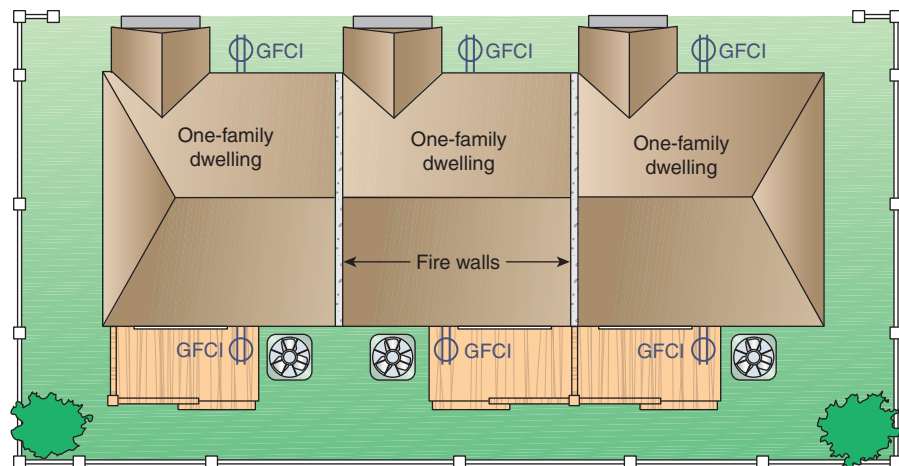

within 25 ft of the HACR equipment. The outlets required by 210.52(E) comply with the “located on the same level” requirement of 210.63. Outdoor receptacle outlets on decks, porches, and similar structures can be used to meet 210.52(E) as long as the receptacle outlet is not more than 6½ ft above grade and can be accessed by a person standing at grade.

**(2) Multifamily Dwellings.** For each dwelling unit of a multifamily dwelling where the dwelling unit is located at grade level and provided with individual exterior entrance/egress, at least one receptacle outlet accessible from grade level and not more than 2.0 m (6½ ft) above grade shall be installed.

Multifamily dwellings (those with three or more dwelling units) are required to be provided with at least one outdoor receptacle outlet accessible from grade level. This requirement applies to those dwelling units in a multifamily structure that are located at grade level and have entrance/egress doorways that lead directly to the exterior of the structure. Concerns over the unauthorized use of outdoor receptacle outlets installed at multifamily dwellings by other than the dwelling occupant(s) can be allayed by using a switch inside the dwelling unit to control the outlet. Due to the spatial constraints often associated with the construction of multifamily units, the required receptacle outlet is permitted to be accessible “from grade,” and an outdoor receptacle outlet located 6½ ft or less above grade and accessible by walking up a set of deck or porch steps can be used to meet this requirement.

**(3) Balconies, Decks, and Porches.** Balconies, decks, and porches that are accessible from inside the dwelling unit shall have at least one receptacle outlet installed within the

**EXHIBIT 210.30** Three one-family dwellings (separated from each other by fire walls) with GFCI-protected receptacles located at the front and the back of each dwelling as required by 210.52(E).

perimeter of the balcony, deck, or porch. The receptacle shall not be located more than 2.0 m (6½ ft) above the balcony, deck, or porch surface.

A porch, balcony, or deck having an overall area of 20 ft<sup>2</sup> or more must have at least one receptacle outlet installed within its perimeter. Because it is an outdoor receptacle, GFCI protection is required. Depending on the location of the porch, balcony, or deck and the location of the receptacle outlet within the perimeter of the porch, deck, or balcony, the receptacle outlet can also be used to meet the outdoor receptacle requirements of 210.52(E)(1) and (E)(2).

•  
**(F) Laundry Areas.** In dwelling units, at least one receptacle outlet shall be installed for the laundry.

*Exception No. 1: In a dwelling unit that is an apartment or living area in a multifamily building where laundry facilities are provided on the premises and are available to all building occupants, a laundry receptacle shall not be required.*

*Exception No. 2: In other than one-family dwellings where laundry facilities are not to be installed or permitted, a laundry receptacle shall not be required.*

A laundry receptacle outlet(s) is supplied by a 20-ampere branch circuit. This circuit can have no other outlets. See 210.11(C)(2) for further information.

**(G) Basements, Garages, and Accessory Buildings.** For a one-family dwelling, the following provisions shall apply:

- (1) At least one receptacle outlet, in addition to those for specific equipment, shall be installed in each basement, in each attached garage, and in each detached garage or accessory building with electric power.
- (2) Where a portion of the basement is finished into one or more habitable rooms, each separate unfinished portion shall have a receptacle outlet installed in accordance with this section.

In a one-family dwelling, a receptacle must be installed in the basement (in addition to the laundry receptacle), in each attached garage, and in each detached garage with electric power.

Section 210.8(A)(5) requires receptacles in unfinished basements to be protected by GFCIs. Section 210.8(A)(2) requires receptacles installed in garages to be protected by GFCIs. Where detached garages are not supplied with electricity, receptacle outlets do not have to be installed.

**(H) Hallways.** In dwelling units, hallways of 3.0 m (10 ft) or more in length shall have at least one receptacle outlet.

As used in this subsection, the hallway length shall be considered the length along the centerline of the hallway without passing through a doorway.

Section 210.52(H) is intended to minimize strain or damage to cords and receptacles for dwelling unit receptacles. The requirement does not apply to common hallways of hotels, motels, apartment buildings, condominiums, and similar occupancies.

**(I) Foyers.** Foyers that are not part of a hallway in accordance with 210.52(H) and that have an area that is greater than 5.6 m<sup>2</sup> (60 ft<sup>2</sup>) shall have a receptacle(s) located in each wall space 900 mm (3 ft) or more in width and unbroken by doorways, floor-to-ceiling windows, and similar openings.

Foyers are not included in the living spaces covered by 210.52(A) even though they may have comparable dimensions in some cases. This requirement provides for receptacle outlets in these spaces to accommodate lamps or other utilization equipment. The primary objective of the requirements covering any of the dwelling areas included in 210.52(A) through (I) is to minimize the need to use extension cords to supply utilization equipment.

## 210.60 Guest Rooms, Guest Suites, Dormitories, and Similar Occupancies

**(A) General.** Guest rooms or guest suites in hotels, motels, sleeping rooms in dormitories, and similar occupancies shall have receptacle outlets installed in accordance with 210.52(A) and (D). Guest rooms or guest suites provided with permanent provisions for cooking shall have receptacle outlets installed in accordance with all of the applicable rules in 210.52.

**(B) Receptacle Placement.** In applying the provisions of 210.52(A), the total number of receptacle outlets shall not be less than the minimum number that would comply with the provisions of that section. These receptacle outlets shall be permitted to be located conveniently for permanent furniture layout. At least two receptacle outlets shall be readily accessible. Where receptacles are installed behind the bed, the receptacle shall be located to prevent the bed from contacting any attachment plug that may be installed or the receptacle shall be provided with a suitable guard.

Section 210.60(B) permits the receptacles in guest rooms and guest suites of hotels and motels and in dormitories to

be placed in accessible locations that are compatible with permanent furniture. However, the minimum number of receptacles required by 210.52 is not permitted to be reduced. The minimum number of receptacle outlets should be determined by assuming there is no furniture in the room. The practical locations of that minimum number of receptacles are then determined based on the permanent furniture layout.

Hotel and motel rooms and suites are commonly used as remote offices for businesspeople who use laptop computers and other plug-in devices. In dormitories, that use of electrical/electronic equipment is significant, necessitating accessible receptacle outlets. The *Code* requires that two receptacle outlets be available without requiring the movement of furniture to access those receptacles. To reduce the risk of fire to bedding material, receptacles located behind beds must include guards if attachment plugs could contact the bed.

Extended-stay hotels and motels are often equipped with permanent provisions for cooking and countertop areas. All applicable receptacle spacing and supply requirements in 210.52 apply to guest rooms or suites that contain such provisions. A portable microwave oven is not considered to be a permanently installed cooking appliance. See 210.18 and its associated commentary for more information regarding hotel and motel guest rooms and guest suites that are equipped with permanent provisions for cooking.

Exhibit 210.31 shows receptacle outlets in a hotel guest room located conveniently with respect to the permanent furniture layout. Some spaces that are 2 ft or more in width have no receptacle outlets because 210.60(B) permits the required number of outlets to be placed in convenient loca-

tions that are compatible with the permanent furniture layout. In Exhibit 210.31, the receptacle outlet adjacent to the permanent dresser is needed because 210.60(B) applies only to the location of receptacle outlets, not to the minimum number of receptacle outlets.

### 210.62 Show Windows

At least one receptacle outlet shall be installed within 450 mm (18 in.) of the top of a show window for each 3.7 linear m (12 linear ft) or major fraction thereof of show window area measured horizontally at its maximum width.

Show windows usually extend from floor to ceiling for maximum display. To discourage floor receptacles and unsightly extension cords likely to cause physical injury, receptacles must be installed directly above a show window, and one receptacle is required for every 12 linear ft or “major fraction thereof” (6 ft or more). See 220.14(G) and 220.43(A) for information regarding load calculations for show windows. To further reduce the use of extension cords, the required receptacle outlet(s) are required to be installed within 18 in. of the top of the show window.

### 210.63 Heating, Air-Conditioning, and Refrigeration Equipment Outlet

A 125-volt, single-phase, 15- or 20-ampere-rated receptacle outlet shall be installed at an accessible location for the servicing of heating, air-conditioning, and refrigeration equipment. The receptacle shall be located on the same level and within 7.5 m (25 ft) of the heating, air-conditioning, and refrigeration equipment. The receptacle outlet shall not be connected to the load side of the equipment disconnecting means.

By requiring a permanently installed receptacle within 25 ft of heating, air-conditioning, and refrigerating (HACR) equipment, 210.63 improves worker safety by eliminating the need to employ makeshift methods of obtaining 125-volt power for servicing and troubleshooting. The exception exempts evaporative coolers (commonly referred to as “swamp coolers”) from the receptacle requirement where the cooler is installed at a one- or two-family dwelling. Although this type of cooling equipment is exempt from 210.63, one- and two-family dwellings are required to have outdoor receptacle outlets at the front and the back of the structure in accordance with 210.52(E).

*Exception: A receptacle outlet shall not be required at one- and two-family dwellings for the service of evaporative coolers.*

**EXHIBIT 210.31** Floor plan of a hotel guest room with receptacles located as permitted by 210.60(B) with respect to permanent furniture.

Informational Note: See 210.8 for ground-fault circuit-interrupter requirements.

### 210.70 Lighting Outlets Required

Lighting outlets shall be installed where specified in 210.70(A), (B), and (C).

**(A) Dwelling Units.** In dwelling units, lighting outlets shall be installed in accordance with 210.70(A)(1), (A)(2), and (A)(3).

**(1) Habitable Rooms.** At least one wall switch-controlled lighting outlet shall be installed in every habitable room and bathroom.

*Exception No. 1: In other than kitchens and bathrooms, one or more receptacles controlled by a wall switch shall be permitted in lieu of lighting outlets.*

A receptacle, controlled by a wall switch, and supplied by other than the circuits covered in 210.11(C)(1) and (2) is permitted to be used as the required lighting outlet in other than kitchens and bathrooms. Exhibit 210.28 shows a switched receptacle supplied by a 15-ampere general-purpose branch circuit in a dining room. See 210.52 for receptacle outlet spacing requirements where switched receptacles are used.

*Exception No. 2: Lighting outlets shall be permitted to be controlled by occupancy sensors that are (1) in addition to wall switches or (2) located at a customary wall switch location and equipped with a manual override that will allow the sensor to function as a wall switch.*

**(2) Additional Locations.** Additional lighting outlets shall be installed in accordance with (A)(2)(a), (A)(2)(b), and (A)(2)(c).

(a) At least one wall switch-controlled lighting outlet shall be installed in hallways, stairways, attached garages, and detached garages with electric power.

(b) For dwelling units, attached garages, and detached garages with electric power, at least one wall switch-controlled lighting outlet shall be installed to provide illumination on the exterior side of outdoor entrances or exits with grade level access. A vehicle door in a garage shall not be considered as an outdoor entrance or exit.

(c) Where one or more lighting outlet(s) are installed for interior stairways, there shall be a wall switch at each floor level, and landing level that includes an entryway, to control the lighting outlet(s) where the stairway between floor levels has six risers or more.

*Exception to (A)(2)(a), (A)(2)(b), and (A)(2)(c): In hallways, in stairways, and at outdoor entrances, remote, central, or automatic control of lighting shall be permitted.*

The requirements of 210.70(A) cover the need for adequate lighting and proper control and location of switching for that lighting in order to facilitate safe movement of dwelling unit occupants. Although 210.70(A)(2)(b) calls for a switched lighting outlet at outdoor entrances and exits, it does not prohibit a single lighting outlet, if suitably located, from serving more than one door.

A wall switch-controlled lighting outlet is required in the kitchen and in the bathroom. A receptacle outlet controlled by a wall switch is not permitted to serve as a lighting outlet in these rooms. Occupancy sensors are permitted to be used for switching lighting outlets in habitable rooms, kitchens, and bathrooms provided they are equipped with a manual override or are used in addition to regular switches.

**(3) Storage or Equipment Spaces.** For attics, underfloor spaces, utility rooms, and basements, at least one lighting outlet containing a switch or controlled by a wall switch shall be installed where these spaces are used for storage or contain equipment requiring servicing. At least one point of control shall be at the usual point of entry to these spaces. The lighting outlet shall be provided at or near the equipment requiring servicing.

Installation of lighting outlets in attics, underfloor spaces or crawl areas, utility rooms, and basements is required when these spaces are used for storage (e.g., holiday decorations or luggage).

If such spaces contain equipment that requires servicing (e.g., air-handling units, cooling and heating equipment, water pumps, or sump pumps), 210.70(C) requires that a lighting outlet be installed in these spaces.

**(B) Guest Rooms or Guest Suites.** In hotels, motels, or similar occupancies, guest rooms or guest suites shall have at least one wall switch-controlled lighting outlet installed in every habitable room and bathroom.

Section 210.70(B) mirrors the language of 210.70(A) and requires a wall switch-controlled lighting outlet in every habitable room (the hotel room or rooms in a suite) and in bathrooms. Where provided, the kitchen is required to have at least one lighting outlet controlled by a wall switch. Rooms other than bathrooms and kitchens can employ a switched receptacle to meet this lighting requirement. Exception No. 2 permits the use of occupancy sensors to control the lighting outlet, provided that it is in the typical switch location and can be manually controlled.

*Exception No. 1: In other than bathrooms and kitchens where provided, one or more receptacles controlled by a wall switch shall be permitted in lieu of lighting outlets.*

*Exception No. 2: Lighting outlets shall be permitted to be controlled by occupancy sensors that are (1) in addition to wall switches or (2) located at a customary wall switch location and equipped with a manual override that allows the sensor to function as a wall switch.*

**(C) Other Than Dwelling Units.** For attics and underfloor spaces containing equipment requiring servicing, such as heating, air-conditioning, and refrigeration equipment, at least one lighting outlet containing a switch or controlled by a wall switch shall be installed in such spaces. At least one point of control shall be at the usual point of entry to these spaces. The lighting outlet shall be provided at or near the equipment requiring servicing.

  - (C) Ungrounded Conductors

#### 215.1 Scope

This article covers the installation requirements, overcurrent protection requirements, minimum size, and ampacity of conductors for feeders supplying branch-circuit loads.

*Exception: Feeders for electrolytic cells as covered in 668.3(C)(1) and (C)(4).*

#### 215.2 Minimum Rating and Size

##### (A) Feeders Not More Than 600 Volts.

**(1) General.** Feeder conductors shall have an ampacity not less than required to supply the load as calculated in Parts III, IV, and V of Article 220. The minimum feeder-circuit conductor size, before the application of any adjustment or correction factors, shall have an allowable ampacity not less than the noncontinuous load plus 125 percent of the continuous load.

Using 250.122 to establish the minimum size grounded conductor in a feeder circuit provides a relationship between the grounded conductor and the feeder circuit overcurrent protective device that is the same as is used for sizing equipment grounding conductors. This sizing requirement provides an adequate fault current path in the event of a fault between a line or phase conductor and the grounded conductor. For feeder circuits installed in parallel in separate raceways or cables, the requirements of 220.61 and 310.10(H) are to be used to determine the minimum grounded conductor size.

Sizing of the grounded feeder conductor is also covered by 215.2(B) for feeder circuits over 600 volts.

*Exception No. 1: If the assembly, including the overcurrent devices protecting the feeder(s), is listed for operation at 100 percent of its rating, the allowable ampacity of the feeder conductors shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.*

*Exception No. 2: Grounded conductors that are not connected to an overcurrent device shall be permitted to be sized at 100 percent of the continuous and noncontinuous load.*

Feeder grounded/neutral conductors that do not connect to the terminals of an overcurrent protective device are not required to be sized based on 125 percent of the continuous load. For example, if the maximum unbalanced load on a feeder neutral is calculated per 220.61 to be 200 amperes and the load is considered to be continuous, the use of a 3/0 AWG THW conductor is permitted as long as the conductor terminates at a neutral bus or terminal bar within the electrical distribution equipment.

**(2) Grounded Conductor.** The size of the feeder circuit grounded conductor shall not be smaller than that required by 250.122, except that 250.122(F) shall not apply where grounded conductors are run in parallel.

Additional minimum sizes shall be as specified in 215.2(A)(2) and (A)(3) under the conditions stipulated.

**(3) Ampacity Relative to Service Conductors.** The feeder conductor ampacity shall not be less than that of the service conductors where the feeder conductors carry the total load supplied by service conductors with an ampacity of 55 amperes or less.

According to Table 310.15(B)(16), a 3/0 AWG, Type THW copper wire has an ampacity of 200 amperes. However, for a 3-wire, single-phase dwelling service, as shown in Exhibit 215.1, Table 310.15(B)(7) permits 2/0 AWG, Type THW copper conductors or 4/0 AWG, Type THW aluminum conductors for services or a main power feeder rated at 200 amperes.

**EXHIBIT 215.1** A 3-wire, single-phase dwelling service with an ampacity of 200 amperes for 2/0 AWG copper or 4/0 AWG aluminum conductors used as service-entrance conductors and feeder conductors, according to 215.2(A)(3).

**(4) Individual Dwelling Unit or Mobile Home Conductors.** Feeder conductors for individual dwelling units or mobile homes need not be larger than service conductors. Paragraph 310.15(B)(6) shall be permitted to be used for conductor size.

Informational Note No. 1: See Examples D1 through D11 in Informative Annex D.

Informational Note No. 2: Conductors for feeders as defined in Article 100, sized to prevent a voltage drop exceeding 3 percent at the farthest outlet of power, heating, and lighting loads, or combinations of such loads, and where the maximum total voltage drop on both feeders and branch circuits to the farthest outlet does not exceed 5 percent, will provide reasonable efficiency of operation.

Informational Note No. 3: See 210.19(A), Informational Note No. 4, for voltage drop for branch circuits.

Reasonable operating efficiency is achieved if the voltage drop of a feeder or a branch circuit is limited to 3 percent. However, the total voltage drop of a branch circuit plus a

feeder can reach 5 percent and still achieve reasonable operating efficiency. See Article 100 for the definitions of *feeder* and *branch circuit*.

The 5 percent voltage-drop value is explanatory material and, as such, appears as an informational note. The informational notes covering voltage drop are not mandatory (see 90.5). Where circuit conductors are increased due to voltage drop, 250.122(B) requires an increase in circular mil area for the associated equipment grounding conductors.

The resistance or impedance of conductors may cause a substantial difference between voltage at service equipment and voltage at the point-of-utilization equipment. Excessive voltage drop impairs the starting and the operation of electrical equipment. Undervoltage can result in inefficient operation of heating, lighting, and motor loads. An applied voltage of 10 percent below rating can result in a decrease in efficiency of substantially more than 10 percent — for example, fluorescent light output would be reduced by 15 percent, and incandescent light output would be reduced by 30 percent. Induction motors would run hotter and produce less torque. With an applied voltage of 10 percent below rating, the running current would increase 11 percent, and the operating temperature would increase 12 percent. At the same time, torque would be reduced 19 percent.

In addition to resistance or impedance, the type of raceway or cable enclosure, the type of circuit (ac, dc, single-phase, 3-phase), and the power factor should be considered to determine voltage drop.

The following basic formula can be used to determine the voltage drop in a 2-wire dc circuit, a 2-wire ac circuit, or a 3-wire ac single-phase circuit, all with a balanced load at 100 percent power factor and where reactance can be neglected:

$$VD = \frac{2 \times L \times R \times I}{1000}$$

where:

$VD$  = voltage drop (based on conductor temperature of 75°C)

$L$  = one-way length of circuit (ft)

$R$  = conductor resistance in ohms ( $\Omega$ ) per 1000 ft (from Chapter 9, Table 8)

$I$  = load current (amperes)

For 3-phase circuits (at 100 percent power factor), the voltage drop between any two phase conductors is 0.866 times the voltage drop calculated by the preceding formula.

#### Calculation Example

Determine the voltage drop in a 240-volt, 2-wire heating circuit with a load of 50 amperes. The circuit size is 6 AWG, Type THHN copper, and the one-way circuit length is 100 ft.

**Solution**

STEP 1. Find the conductor resistance in Chapter 9, Table 8.

STEP 2. Substitute values into the voltage-drop formula:

$$VD = \frac{2 \times L \times R \times I}{1000}$$

$$= \frac{2 \times 100 \times 0.491 \times 50}{1000} = 4.91 \text{ volts}$$

STEP 3. Determine the percentage of the voltage drop:

$$\%VD = \frac{4.91 \text{ V}}{240 \text{ V}} = 0.02 \text{ or } 2\%$$

A 12-volt drop on a 240-volt circuit is a 5 percent drop. A 4.91-volt drop falls within this percentage. If the total voltage drop exceeds 5 percent, or 12 volts, larger-size conductors should be used, the circuit length should be shortened, or the circuit load should be reduced.

See the commentary following Chapter 9, Table 9, for an example of voltage-drop calculation using ac reactance and resistance. Voltage-drop tables and calculations are also available from various manufacturers.

**(B) Feeders over 600 Volts.** The ampacity of conductors shall be in accordance with 310.15 and 310.60 as applicable. Where installed, the size of the feeder-circuit grounded conductor shall not be smaller than that required by 250.122, except that 250.122(F) shall not apply where grounded conductors are run in parallel. Feeder conductors over 600 volts shall be sized in accordance with 215.2(B)(1), (B)(2), or (B)(3).

**(1) Feeders Supplying Transformers.** The ampacity of feeder conductors shall not be less than the sum of the nameplate ratings of the transformers supplied when only transformers are supplied.

**(2) Feeders Supplying Transformers and Utilization Equipment.** The ampacity of feeders supplying a combination of transformers and utilization equipment shall not be less than the sum of the nameplate ratings of the transformers and 125 percent of the designed potential load of the utilization equipment that will be operated simultaneously.

**(3) Supervised Installations.** For supervised installations, feeder conductor sizing shall be permitted to be determined by qualified persons under engineering supervision. Supervised installations are defined as those portions of a facility where all of the following conditions are met:

- (1) Conditions of design and installation are provided under engineering supervision.

- (2) Qualified persons with documented training and experience in over 600-volt systems provide maintenance, monitoring, and servicing of the system.

Section 215.2(B) sets the minimum requirements for feeders over 600 volts. Unless the circuit is part of a supervised installation [defined in 215.2(B)(3)], the minimum ampacity for feeder circuit conductors over 600 volts can be no less than 100 percent of the transformer nameplate load plus 125 percent of any additional utilization equipment. The overcurrent protection requirements for feeders over 600 volts must be in accordance with Article 240, Part IX.

### 215.3 Overcurrent Protection

Feeders shall be protected against overcurrent in accordance with the provisions of Part I of Article 240. Where a feeder supplies continuous loads or any combination of continuous and noncontinuous loads, the rating of the overcurrent device shall not be less than the noncontinuous load plus 125 percent of the continuous load.

*Exception No. 1: Where the assembly, including the overcurrent devices protecting the feeder(s), is listed for operation at 100 percent of its rating, the ampere rating of the overcurrent device shall be permitted to be not less than the sum of the continuous load plus the noncontinuous load.*

*Exception No. 2: Overcurrent protection for feeders over 600 volts, nominal, shall comply with Part IX of Article 240.*

The feeder overcurrent protection requirements in 215.3 are somewhat similar to the branch-circuit overcurrent protection requirements in 210.20(A).

### 215.4 Feeders with Common Neutral Conductor

**(A) Feeders with Common Neutral.** Up to three sets of 3-wire feeders or two sets of 4-wire or 5-wire feeders shall be permitted to utilize a common neutral.

**(B) In Metal Raceway or Enclosure.** Where installed in a metal raceway or other metal enclosure, all conductors of all feeders using a common neutral conductor shall be enclosed within the same raceway or other enclosure as required in 300.20.

If feeder conductors carrying ac current, including the neutral, are installed in metal raceways, the conductors are required to be grouped together to avoid induction heating of

the surrounding metal. If it is necessary to run parallel conductors through multiple metal raceways, conductors from each phase plus the neutral must be run in each raceway. See 250.102(E), 250.134(B), 300.3, 300.5(I), and 300.20 for requirements associated with conductor grouping of feeder circuits.

A 3-phase, 4-wire (208Y/120-volt, 480Y/277-volt) system is often used to supply both lighting and motor loads. The 3-phase motor loads are typically not connected to the neutral and thus will not cause current in the neutral conductor. The maximum current on the neutral, therefore, is due to lighting loads or circuits where the neutral is used. On this type of system (3-phase, 4-wire), a demand factor of 70 percent is permitted by 220.61 for that portion of the neutral load in excess of 200 amperes.

For example, if the maximum possible unbalanced load is 500 amperes, the neutral would have to be large enough to carry 410 amperes (200 amperes plus 70 percent of 300 amperes, or 410 amperes). No reduction of the neutral capacity for that portion of the load consisting of electric-discharge lighting is permitted.

Section 310.15(B)(5)(c) points out that a neutral conductor must be counted as a current-carrying conductor if the load it serves consists of harmonic currents. See 220.61 for other systems in which the 70 percent demand factor may be applied. The maximum unbalanced load for feeders supplying clothes dryers, household ranges, wall-mounted ovens, and counter-mounted cooking units is required to be considered 70 percent of the load on the ungrounded conductors. See Examples D1(a) through D5(b) of Informative Annex D.

## 215.5 Diagrams of Feeders

If required by the authority having jurisdiction, a diagram showing feeder details shall be provided prior to the installation of the feeders. Such a diagram shall show the area in square feet of the building or other structure supplied by each feeder, the total calculated load before applying demand factors, the demand factors used, the calculated load after applying demand factors, and the size and type of conductors to be used.

## 215.6 Feeder Equipment Grounding Conductor

Where a feeder supplies branch circuits in which equipment grounding conductors are required, the feeder shall include or provide an equipment grounding conductor in accordance with the provisions of 250.134, to which the equipment grounding conductors of the branch circuits shall be connected. Where the feeder supplies a separate building or structure, the requirements of 250.32(B) shall apply.

## 215.7 Ungrounded Conductors Tapped from Grounded Systems

Two-wire dc circuits and ac circuits of two or more ungrounded conductors shall be permitted to be tapped from the ungrounded conductors of circuits having a grounded neutral conductor. Switching devices in each tapped circuit shall have a pole in each ungrounded conductor.

Section 215.7 does not require a common trip or simultaneous opening of circuit breakers or fuses but rather requires a switching device to manually disconnect the ungrounded conductors of the feeder. See 210.10 for similar requirements related to the ungrounded conductors of the branch circuit.

## 215.9 Ground-Fault Circuit-Interrupter Protection for Personnel

Feeders supplying 15- and 20-ampere receptacle branch circuits shall be permitted to be protected by a ground-fault circuit interrupter in lieu of the provisions for such interrupters as specified in 210.8 and 590.6(A).

Ground-fault circuit-interrupter protection of the feeder circuit protects all branch-circuits supplied by that feeder. This type of GFCI installation is permitted in lieu of the requirements of 210.8(A) or (B). GFCI protection in the feeder can also be used to protect construction-site receptacles, as covered in 590.6(A), provided the feeder supplies no lighting branch circuits.

It may be more economical or convenient to install GFCIs for feeders. However, consideration should be given to the fact that a GFCI may be monitoring several branch circuits and will de-energize all branch circuits in response to a line-to-ground fault from one branch circuit.

## 215.10 Ground-Fault Protection of Equipment

Each feeder disconnect rated 1000 amperes or more and installed on solidly grounded wye electrical systems of more than 150 volts to ground, but not exceeding 600 volts phase-to-phase, shall be provided with ground-fault protection of equipment in accordance with the provisions of 230.95.

Informational Note: For buildings that contain health care occupancies, see the requirements of 517.17.

*Exception No. 1: The provisions of this section shall not apply to a disconnecting means for a continuous industrial process where a nonorderly shutdown will introduce additional or increased hazards.*

Section 215.10 requires ground-fault protection of equipment for feeder disconnects that are rated 1000 amperes or more and operate at 480Y/277 volts. A similar requirement for services is found in 230.95. The reason for the requirement was the unusually high number of burndowns reported on feeders and services operating in this voltage range. Solidly grounded systems operating at 480Y/277 volts were the primary focus of this requirement when it was first introduced in the *Code*, but there are other solidly grounded, wye-connected systems operating over 150 volts to ground and not more than 600 volts phase-to-phase that are covered by this requirement. Prior to being put into service, each ground-fault protection system must be performance tested and documented according to the requirements of 230.95(C).

Ground-fault protection of feeder equipment is not required if protection is provided on an upstream feeder or at the service. However, additional levels of ground-fault protection on feeders may be desired so that a single ground fault does not de-energize the whole electrical system. See 230.95 for further commentary on ground-fault protection of services. Also, see 517.17, which requires an additional level of ground-fault protection for health care facilities.

For emergency feeders covered within the scope of Article 700, the ground-fault protection requirements are different. See 700.26 for further details.

*Exception No. 2: The provisions of this section shall not apply if ground-fault protection of equipment is provided on the supply side of the feeder and on the load side of any transformer supplying the feeder.*

Ground-fault protection installed in equipment supplying a transformer will not function to protect equipment supplied by the secondary of the transformer. If the equipment supplied by the secondary of the transformer meets the parameters under which ground-fault protection of equipment (GFPE) is required by 215.10, protection must be installed within that equipment notwithstanding any GFPE installed in equipment supplying the transformer.

### 215.11 Circuits Derived from Autotransformers

Feeders shall not be derived from autotransformers unless the system supplied has a grounded conductor that is electrically connected to a grounded conductor of the system supplying the autotransformer.

*Exception No. 1: An autotransformer shall be permitted without the connection to a grounded conductor where*

*transforming from a nominal 208 volts to a nominal 240-volt supply or similarly from 240 volts to 208 volts.*

*Exception No. 2: In industrial occupancies, where conditions of maintenance and supervision ensure that only qualified persons service the installation, autotransformers shall be permitted to supply nominal 600-volt loads from nominal 480-volt systems, and 480-volt loads from nominal 600-volt systems, without the connection to a similar grounded conductor.*

Section 215.11 addresses autotransformers for feeders and is similar to the requirements in 210.9 for branch circuits. See the commentary following 210.9 for further information on autotransformers that supply branch circuits.

### 215.12 Identification for Feeders

**(A) Grounded Conductor.** The grounded conductor of a feeder shall be identified in accordance with 200.6.

**(B) Equipment Grounding Conductor.** The equipment grounding conductor shall be identified in accordance with 250.119.

**(C) Ungrounded Conductors.** Where the premises wiring system has feeders supplied from more than one nominal voltage system, each ungrounded conductor of a feeder shall be identified by phase or line and system at all termination, connection, and splice points. The means of identification shall be permitted to be by separate color coding, marking tape, tagging, or other approved means. The method utilized for conductors originating within each feeder panelboard or similar feeder distribution equipment shall be documented in a manner that is readily available or shall be permanently posted at each feeder panelboard or similar feeder distribution equipment.

Parallel with the requirement for ungrounded branch circuit conductors in 210.5(C), 215.12(C) requires identification of ungrounded feeder conductors by system and phase where there is more than one nominal voltage supply system to a building, structure, or other premises. The identification scheme is not specified, but whatever is used is required to be consistent throughout the premises. A permanent legend or directory indicating the feeder identification system for the premises is required to be posted at each point in the distribution system from which feeder circuits are supplied or the identification scheme is to be described in a facility log or other documentation and made readily available. Exhibit 215.2 is an example of the use of different colors to identify each ungrounded line or phase of a nominal voltage system.

**EXHIBIT 215.2** Different colors being used to identify each ungrounded line or phase conductor of a nominal voltage system.

## I. General

### 220.1 Scope

This article provides requirements for calculating branch-circuit, feeder, and service loads. Part I provides for general requirements for calculation methods. Part II provides calculation methods for branch-circuit loads. Parts III and IV provide calculation methods for feeders and services. Part V provides calculation methods for farms.

Article 220 contains requirements for calculating branch-circuit, feeder, and service loads. Although this article does not contain the requirements for determining the minimum number of branch circuits, the loads calculated in accordance with Article 220 are used in conjunction with the rules of 210.11 to determine how many branch circuits are needed at a premises. Table 220.3 identifies other articles and sections with load calculation requirements.

Informational Note: See Figure 220.1 for information on the organization of Article 220.

### 220.3 Application of Other Articles

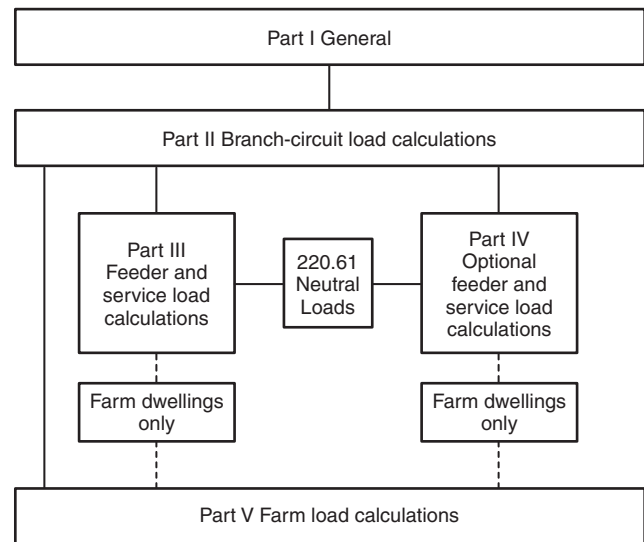

In other articles applying to the calculation of loads in specialized applications, there are requirements provided in Table 220.3 that are in addition to, or modifications of, those within this article.

### 220.5 Calculations

**(A) Voltages.** Unless other voltages are specified, for purposes of calculating branch-circuit and feeder loads, nominal system voltages of 120, 120/240, 208Y/120, 240, 347, 480Y/277, 480, 600Y/347, and 600 volts shall be used.

**(B) Fractions of an Ampere.** Calculations shall be permitted to be rounded to the nearest whole ampere, with decimal fractions smaller than 0.5 dropped.

For uniform calculation of load, nominal voltages, as listed in 220.5(A), are required to be used in computing the am-

**FIGURE 220.1** Branch-Circuit, Feeder, and Service Calculation Methods.

pere load on the conductors. To select conductor sizes, refer to 310.15(A) and (B).

Loads are calculated on the basis of volt-amperes (VA) or kilovolt-amperes (kVA), rather than watts or kilowatts (kW), to calculate the true ampere values. However, the rating of equipment is given in watts or kilowatts for noninductive loads. Such ratings are considered to be the equivalent of the same rating in volt-amperes or kilovolt-amperes. See, for example, 220.55. This concept recognizes that load calculations determine conductor and circuit sizes, that the power factor of the load is often unknown, and that the conductor “sees” the circuit volt-amperes only, not the circuit power (watts).

See Examples D1(a) through D5(b) in Informative Annex D. The results of these examples are generally expressed in amperes. In these examples, fractions of an ampere are rounded to the nearest whole ampere with decimal fractions less than 0.5 amperes dropped per 220.5(B).

## II. Branch-Circuit Load Calculations

### 220.10 General

Branch-circuit loads shall be calculated as shown in 220.12, 220.14, and 220.16.

### 220.12 Lighting Load for Specified Occupancies

A unit load of not less than that specified in Table 220.12 for occupancies specified therein shall constitute the minimum lighting load. The floor area for each floor shall be calculated from the outside dimensions of the building, dwelling

TABLE 220.3 Additional Load Calculation References

Calculation	Article	Section (or Part)
Air-conditioning and refrigerating equipment, branch-circuit conductor sizing	440	Part IV
Cranes and hoists, rating and size of conductors	610	610.14

Theaters, stage switchboard feeders	520	520.27

unit, or other area involved. For dwelling units, the calculated floor area shall not include open porches, garages, or unused or unfinished spaces not adaptable for future use.

Informational Note: The unit values herein are based on minimum load conditions and 100 percent power factor and may not provide sufficient capacity for the installation contemplated.

General lighting loads determined by 220.12 are in fact minimum lighting loads, and there are no exceptions to these requirements. Therefore, energy saving-type calculations are not permitted to be used to determine the minimum calculated lighting load if they produce loads less than the load calculated according to 220.12. On the other hand, energy saving-type calculations can be a useful tool to reduce the connected lighting load and actual power consumption.

Examples of unused or unfinished spaces for dwelling units are some attics, cellars, and crawl spaces.

## 220.14 Other Loads — All Occupancies

In all occupancies, the minimum load for each outlet for general-use receptacles and outlets not used for general illumination shall not be less than that calculated in 220.14(A) through (L), the loads shown being based on nominal branch-circuit voltages.

*Exception: The loads of outlets serving switchboards and switching frames in telephone exchanges shall be waived from the calculations.*

**(A) Specific Appliances or Loads.** An outlet for a specific appliance or other load not covered in 220.14(B) through (L) shall be calculated based on the ampere rating of the appliance or load served.

**(B) Electric Dryers and Electric Cooking Appliances in Dwelling Units.** Load calculations shall be permitted as specified in 220.54 for electric dryers and in 220.55 for electric ranges and other cooking appliances.

**(C) Motor Loads.** Outlets for motor loads shall be calculated in accordance with the requirements in 430.22, 430.24, and 440.6.

**(D) Luminaires.** An outlet supplying luminaire(s) shall be calculated based on the maximum volt-ampere rating of the equipment and lamps for which the luminaire(s) is rated.

In general, no additional calculation is required for luminaires (recessed and surface mounted) installed in or on a dwelling unit, because the load of such luminaires is covered in the 3 volt-amperes per square foot calculation specified by Table 220.12. Where the rating of the luminaires installed for general lighting exceeds the minimum load provided for in Table 220.12, the minimum general lighting load for that premises must be based on the installed luminaires. Distinguishing between the luminaires installed for general lighting versus those installed for accent, specialty, or display lighting is much easier to delineate in commercial (particularly mercantile) occupancies.

**(E) Heavy-Duty Lampholders.** Outlets for heavy-duty lampholders shall be calculated at a minimum of 600 volt-amperes.

**(F) Sign and Outline Lighting.** Sign and outline lighting outlets shall be calculated at a minimum of 1200 volt-amperes for each required branch circuit specified in 600.5(A).

Section 220.14(F) assigns 1200 volt-amperes as a minimum circuit load for the signs and outline lighting outlets required by 600.5(A). If the specific load for signs and outline lighting outlets is known to be larger than specified by 220.14, the actual load is used for calculation purposes.

**(G) Show Windows.** Show windows shall be calculated in accordance with either of the following:

- (1) The unit load per outlet as required in other provisions of this section
- (2) At 200 volt-amperes per 300 mm (1 ft) of show window

The following two options are permitted for the load calculations for branch circuits serving show windows:

1. 180 volt-amperes per receptacle according to 210.62, which requires one receptacle per 12 linear ft
2. 200 volt-amperes per linear foot of show-window space

As shown in Exhibit 220.1, the linear-foot calculation method is permitted in lieu of the specified unit load per outlet for branch circuits serving show windows.

**TABLE 220.12 General Lighting Loads by Occupancy**

Type of Occupancy	Unit Load	
	Volt-Amperes/ Square Meter	Volt-Amperes/ Square Foot
Armories and auditoriums	11	1
Banks	39 <sup>b</sup>	3½ <sup>b</sup>
Barber shops and beauty parlors	33	3
Churches	11	1
Clubs	22	2
Court rooms	22	2
Dwelling units <sup>a</sup>	33	3
Garages — commercial (storage)	6	½
Hospitals	22	2
Hotels and motels, including apartment houses without provision for cooking by tenants <sup>a</sup>	22	2
Industrial commercial (loft) buildings	22	2
Lodge rooms	17	1½
Office buildings	39 <sup>b</sup>	3½ <sup>b</sup>
Restaurants	22	2
Schools	33	3
Stores	33	3
Warehouses (storage)	3	¼
In any of the preceding occupancies except one-family dwellings and individual dwelling units of two-family and multifamily dwellings:		
Assembly halls and auditoriums	11	1
Halls, corridors, closets, stairways	6	½
Storage spaces	3	¼

<sup>a</sup>See 220.14(J).

<sup>b</sup>See 220.14(K).

**(H) Fixed Multioutlet Assemblies.** Fixed multioutlet assemblies used in other than dwelling units or the guest rooms or guest suites of hotels or motels shall be calculated in accordance with (H)(1) or (H)(2). For the purposes of this section, the calculation shall be permitted to be based on the portion that contains receptacle outlets.

- (1) Where appliances are unlikely to be used simultaneously, each 1.5 m (5 ft) or fraction thereof of each separate and continuous length shall be considered as one outlet of not less than 180 volt-amperes.
- (2) Where appliances are likely to be used simultaneously, each 300 mm (1 ft) or fraction thereof shall be considered as an outlet of not less than 180 volt-amperes.

**EXHIBIT 220.1** An example of the volt-ampere per linear-foot load calculation for branch circuits serving a show window.

Section 220.14 covers two conditions of use for fixed multioutlet assemblies, which are common in commercial and industrial locations. The first area of use is light use, which means that not all the cord-connected equipment is expected to be used at the same time, as defined in 220.14(H)(1). An example of light use is a workbench area where one worker uses one electrical tool at a time. The second area of use is heavy use, which is characterized by all the cord-connected equipment generally operating at the same time, as defined in 220.14(H)(2). An example of heavy use is a retail outlet displaying television sets, where most, if not all, sets are operating simultaneously.

As shown in Exhibit 220.2, the requirement of 220.14(H)(1) states that each 5 ft of a fixed multioutlet assembly must be considered as one outlet rated 180 volt-amperes. The requirement of 220.14(H)(2) states that where appliances are likely to be used simultaneously, each foot of

**EXHIBIT 220.2** The requirements of 220.14(H)(1) and (H)(2) as applied to fixed multioutlet assemblies.

multioutlet assembly is to be considered as one outlet rated 180 volt-amperes.

**(I) Receptacle Outlets.** Except as covered in 220.14(J) and (K), receptacle outlets shall be calculated at not less than 180 volt-amperes for each single or for each multiple receptacle on one yoke. A single piece of equipment consisting of a multiple receptacle comprised of four or more receptacles shall be calculated at not less than 90 volt-amperes per receptacle. This provision shall not be applicable to the receptacle outlets specified in 210.11(C)(1) and (C)(2).

In accordance with 220.14(I), Exhibit 220.3 shows the load of 180 volt-amperes applied to single and multiple receptacles mounted on a single yoke or strap, and the load of 360 volt-amperes applied to the outlet containing two duplex receptacles and to the outlet containing the device with four receptacles. The receptacle outlets are not the lighting outlets installed for general illumination or the small-appliance branch circuits, as indicated in 220.14(J). The receptacle load for outlets for general illumination in one- and two-family and multifamily dwellings and in guest rooms of hotels and motels is included in the general lighting load value assigned by Table 220.12. The load requirement for the small-appliance branch circuits is 1500 volt-amperes per circuit, as described in 220.52(A).

Note in Exhibit 220.3 that the last outlet of the top circuit consists of two duplex receptacles on separate straps. That outlet is calculated at 360 volt-amperes because each duplex receptacle is on one yoke. The multiple receptacle supplied from the bottom circuit in the exhibit, which comprises four receptacles, is calculated at 90 volt-amperes per receptacle ( $4 \times 90 \text{ VA} = 360 \text{ VA}$ ). For example, single-strap and multiple-receptacle devices are calculated as follows:

**EXHIBIT 220.3** The load requirement of 180 volt-amperes per 220.14(I) as applied to single- and multiple-receptacle outlets on single straps and the load of 360 volt-amperes applied to a multiple device consisting of four receptacles.

Device	Calculated Load
Duplex receptacle	180 VA
Triplex receptacle	180 VA
Double duplex receptacle	360 VA (180 × 2)
Quad or four-plex-type receptacle	360 VA (90 × 4)

A load of 180 volt-amperes is not required to be considered for outlets supplying recessed lighting fixtures, lighting outlets for general illumination, and small-appliance branch circuits. To apply the requirement of 180 volt-amperes in those cases would be unrealistic, because it would unnecessarily restrict the number of lighting or receptacle outlets on branch circuits in dwelling units. See the note below Table 220.12 that references 220.14(J). This note indicates that the requirement of 180 volt-amperes does not apply to most receptacle outlets in dwellings.

In Exhibit 220.4, the maximum number of outlets permitted on 15- and 20-ampere branch circuits is 10 and 13 outlets, respectively, based on the load assigned for each outlet by 220.14(I). This restriction does not apply to outlets connected to general lighting or small-appliance branch circuits in dwelling units.

**(J) Dwelling Occupancies.** In one-family, two-family, and multifamily dwellings and in guest rooms or guest suites of hotels and motels, the outlets specified in (J)(1), (J)(2), and (J)(3) are included in the general lighting load calculations of 220.12. No additional load calculations shall be required for such outlets.

- (1) All general-use receptacle outlets of 20-ampere rating or less, including receptacles connected to the circuits in 210.11(C)(3)
- (2) The receptacle outlets specified in 210.52(E) and (G)
- (3) The lighting outlets specified in 210.70(A) and (B)

**(K) Banks and Office Buildings.** In banks or office buildings, the receptacle loads shall be calculated to be the larger of (1) or (2):

- (1) The calculated load from 220.14(I)
- (2) 11 volt-amperes/m<sup>2</sup> or 1 volt-ampere/ft<sup>2</sup>

**(L) Other Outlets.** Other outlets not covered in 220.14(A) through (K) shall be calculated based on 180 volt-amperes per outlet.

### 220.16 Loads for Additions to Existing Installations

**(A) Dwelling Units.** Loads added to an existing dwelling unit(s) shall comply with the following as applicable:

- (1) Loads for structural additions to an existing dwelling unit or for a previously unwired portion of an existing dwelling unit, either of which exceeds 46.5 m<sup>2</sup> (500 ft<sup>2</sup>), shall be calculated in accordance with 220.12 and 220.14.
- (2) Loads for new circuits or extended circuits in previously wired dwelling units shall be calculated in accordance with either 220.12 or 220.14, as applicable.

**(B) Other Than Dwelling Units.** Loads for new circuits or extended circuits in other than dwelling units shall be calculated in accordance with either 220.12 or 220.14, as applicable.

### 220.18 Maximum Loads

The total load shall not exceed the rating of the branch circuit, and it shall not exceed the maximum loads specified in 220.18(A) through (C) under the conditions specified therein.

**(A) Motor-Operated and Combination Loads.** Where a circuit supplies only motor-operated loads, Article 430 shall apply. Where a circuit supplies only air-conditioning equipment, refrigerating equipment, or both, Article 440 shall apply. For circuits supplying loads consisting of motor-operated utilization equipment that is fastened in place and has a motor larger than 1/8 hp in combination with other loads, the total calculated load shall be based on 125 percent of the largest motor load plus the sum of the other loads.

**EXHIBIT 220.4** Maximum number of outlets permitted on 15- and 20-ampere branch circuits.

**(B) Inductive and LED Lighting Loads.** For circuits supplying lighting units that have ballasts, transformers, auto-transformers, or LED drivers, the calculated load shall be based on the total ampere ratings of such units and not on the total watts of the lamps.

**(C) Range Loads.** It shall be permissible to apply demand factors for range loads in accordance with Table 220.55, including Note 4.

### III. Feeder and Service Load Calculations

#### 220.40 General

The calculated load of a feeder or service shall not be less than the sum of the loads on the branch circuits supplied, as determined by Part II of this article, after any applicable demand factors permitted by Part III or IV or required by Part V have been applied.

Informational Note: See Examples D1(a) through D10 in Informative Annex D. See 220.18(B) for the maximum load in amperes permitted for lighting units operating at less than 100 percent power factor.

In the example shown in Exhibit 220.5, each panelboard supplies a calculated load of 80 amperes. The main set of service conductors is sized to carry the total calculated load of 240 amperes ( $3 \times 80$  amperes). The service conductors from the meter enclosure to each panelboard [2 AWG Cu = 95 amperes per 60°C column of Table 310.15(B)(16)] are sized to supply a calculated load of 80 amperes and to meet the requirement of 230.90 relative to overcurrent (overload) protection of service conductors terminating in a single service overcurrent protective device. The main set of service conductors [250 kcmil THWN Cu = 255 amperes per 75°C

**EXHIBIT 220.5** Service conductors sized in accordance with 220.40.

column of Table 310.15(B)(16)] is not required to be sized to carry 300 amperes based on the combined rating of the panelboards. The individual service-entrance conductors to each panelboard (2 AWG THWN) meet the requirement of 230.90.

See Exhibit 230.26 for a similar example. In that example, the ungrounded service conductors are not required to be sized for the sum of the main overcurrent device ratings of 350 amperes. Service conductors are required to have sufficient ampacity to carry the loads calculated in accordance with Article 220, with the appropriate demand factors applied. See 230.23, 230.31, and 230.42 for specifics on size and rating of service conductors.

Part III of Article 220 contains the requirements for calculating feeder and service loads. Part IV provides optional methods for calculating feeder and service loads in dwelling units and multifamily dwellings.

Except as permitted in 240.4 and 240.6, the rating of the overcurrent device cannot exceed the final ampacity of the circuit conductors after all the correction and adjustment factors have been applied, such as where the ambient temperature, the number of current-carrying conductors, or both exceed the parameters on which the allowable ampacity table values are based.

#### Calculation Example

Determine the minimum-size overcurrent protective device (OCPD) and the minimum conductor size for a feeder circuit with the following characteristics:

- 3-phase, 4-wire feeder (full-size neutral)
- 125-ampere noncontinuous load
- 200-ampere continuous load
- 75°C overcurrent device terminal rating
- Type THWN insulated conductors
- Four current-carrying conductors in a raceway
- A load the majority of which is nonlinear

#### Solution

STEP 1. Select the feeder OCPD rating by first totaling the continuous and noncontinuous loads according to 215.3:

$$\begin{aligned} \text{OCPD rating} &= 125\% \text{ of continuous load} \\ &\quad + \text{noncontinuous load} \\ &= (200 \text{ A} \times 1.25) + 125 \text{ A} \\ &= 250 \text{ A} + 125 \text{ A} \\ &= 375 \text{ A} \end{aligned}$$

Using 240.4(B) and 240.6(A), adjust the minimum standard-size OCPD to 400 amperes.

STEP 2. Select the feeder conductor size before derating by first summing the continuous and noncontinuous loads according to 215.2(A)(1).

$$\begin{aligned}
 \text{Feeder size} &= 125\% \text{ of continuous load} \\
 \text{(before derating)} &+ \text{noncontinuous load} \\
 &= (200 \text{ A} \times 1.25) + 125 \text{ A} \\
 &= 250 \text{ A} + 125 \text{ A} \\
 &= 375 \text{ A}
 \end{aligned}$$

Using the 75°C column of Table 310.15(B)(16) (because of the overcurrent device terminal), the minimum-size Type THWN copper conductor that can supply a calculated load of 375 amperes is 500-kcmil copper, which has an ampacity of 380 amperes.

STEP 3. Apply the adjustment factor to the feeder conductor size. Section 310.15(B)(5)(c) requires that the neutral conductor be counted as a current-carrying conductor because a major portion of the load consists of fluorescent and high-intensity discharge (HID) luminaires. Therefore, this feeder circuit consists of four current-carrying conductors in the same raceway. Section 310.15(B)(3) requires an 80 percent adjustment factor for four current-carrying conductors in the same raceway. According to Table 310.15(B)(16), 500-kcmil, Type THWN conductors have an ampacity of 380 amperes. The adjustment factors are applied to this ampacity as follows:

$$\begin{aligned}
 \text{Adjusted ampacity} &= \text{Table ampacity} \times \text{adjustment factor} \\
 &= 380 \text{ A} \times 0.80 \\
 &= 304 \text{ A}
 \end{aligned}$$

According to 240.4(B) and 240.6(A), a conductor with a calculated ampacity of 304 amperes is not permitted to be protected by a 400-ampere OCPD. Therefore, the 500-kcmil, Type THWN copper conductor cannot be used.

STEP 4. Revise the feeder conductor selection and perform a check. The next standard-size conductor listed in Table 310.15(B)(16) is a 600-kcmil copper conductor in the 90°C column. If higher-temperature insulations are used, adjustment factors can be applied to the higher ampacity. Because Type THWN is a 75°C insulation, a 90°C Type THHN is selected. If a 600-kcmil Type THHN copper conductor is used, perform the check as follows. According to Table 310.15(B)(16), a 600-kcmil conductor has an ampacity of 475 amperes in the Type THHN 90°C column:

$$\begin{aligned}
 \text{Adjusted ampacity} &= \text{Table ampacity} \times \text{adjustment factor} \\
 &= 475 \text{ A} \times 0.80 \\
 &= 380 \text{ A}
 \end{aligned}$$

A conductor with a calculated ampacity of 380 amperes is allowed to be protected by a 400-ampere OCPD, in accordance with 240.4(B). However, because the OCPD terminations are rated 75°C, the load current cannot exceed the ampacity of a 600-kcmil conductor in the 75°C column of Table 310.15(B)(16), which has a value of 420 amperes.

STEP 5. Evaluate the circuit. The calculation in Step 4 results in four 600-kcmil Type THHN copper conductors in one raceway, each with an ampacity of 380 amperes, supplying a 375-ampere continuous load and protected by a 400-ampere OCPD. It is important to note here that a 90°C, 600-kcmil copper conductor with a final calculated ampacity of 380 amperes is permitted to terminate on a 75°C-rated terminal, according to 110.14(C)(1)(b)(2).

## 220.42 General Lighting

The demand factors specified in Table 220.42 shall apply to that portion of the total branch-circuit load calculated for general illumination. They shall not be applied in determining the number of branch circuits for general illumination.

**TABLE 220.42 Lighting Load Demand Factors**

Type of Occupancy	Portion of Lighting Load to Which Demand Factor Applies (Volt-Amperes)	Demand Factor (%)
Dwelling units	First 3000 or less at	100
	From 3001 to 120,000 at	35
	Remainder over 120,000 at	25
Hospitals*	First 50,000 or less at	40
	Remainder over 50,000 at	20
Hotels and motels, including apartment houses without provision for cooking by tenants*	First 20,000 or less at	50
	From 20,001 to 100,000 at	40
	Remainder over 100,000 at	30
Warehouses (storage)	First 12,500 or less at	100
	Remainder over 12,500 at	50
All others	Total volt-amperes	100

\*The demand factors of this table shall not apply to the calculated load of feeders or services supplying areas in hospitals, hotels, and motels where the entire lighting is likely to be used at one time, as in operating rooms, ballrooms, or dining rooms.

## 220.43 Show-Window and Track Lighting

(A) **Show Windows.** For show-window lighting, a load of not less than 660 volt-amperes/linear meter or 200 volt-amperes/linear foot shall be included for a show window, measured horizontally along its base.

Informational Note: See 220.14(G) for branch circuits supplying show windows.

The calculation of 200 volt-amperes for each linear foot of a show window is required to determine the feeder load. See the commentary following 220.14(G) for load calculations for branch circuits in show windows.

**(B) Track Lighting.** For track lighting in other than dwelling units or guest rooms or guest suites of hotels or motels, an additional load of 150 volt-amperes shall be included for every 600 mm (2 ft) of lighting track or fraction thereof. Where multicircuit track is installed, the load shall be considered to be divided equally between the track circuits.

#### Calculation Example

A lighting plan shows 62.5 linear ft of single-circuit track lighting for a small department store featuring clothing. Because the actual track lighting fixtures are owner supplied, neither the quantity of track lighting fixtures nor the lamp size is specified. What is the minimum calculated load associated with the track lighting that must be added to the service or feeder supplying this store?

#### Solution

According to 220.43(B), the minimum calculated load to be added to the service or feeder supplying this track light installation is calculated as follows:

$$\frac{62.5 \text{ ft}}{2 \text{ ft}} = 31.25, \text{ rounded up to } 32$$

$$32 \times 150 \text{ VA} = 4800 \text{ VA}$$

The minimum load for the lighting track that is added to the service and/or feeder calculation is 4800 volt-amperes.

It is important to note that the branch circuits supplying this installation are covered in 410.151(B). For the track lighting branch-circuit load, the maximum load on the track cannot exceed the rating of the branch circuit supplying the track. Also, the track must be supplied by a branch circuit that has a rating not exceeding the rating of the track. The track length does not enter into the branch-circuit calculation.

Section 220.43(B) is not intended to limit the number of feet of track on a single branch circuit, nor is it intended to limit the number of fixtures on an individual track. Rather, 220.43(B) is meant to be used solely for load calculations of feeders and services.

*Exception: If the track lighting is supplied through a device that limits the current to the track, the load shall be permitted to be calculated based on the rating of the device used to limit the current.*

The exception to 220.43(B) permits the track lighting load to be calculated based on the current rating of a “device used

to limit the current.” The rating of the branch circuit overcurrent protective device can be used for this calculation, or the device used to limit current can be a supplementary overcurrent protective device. This exception enables load calculations to be more in line with the limitations placed on building lighting loads by local and federal energy codes.

#### Calculation Example

A lighting plan shows 62.5 linear ft of single-circuit track lighting for a small department store featuring clothing. Because the actual track lighting fixtures are owner supplied, neither the quantity of track lighting fixtures nor the lamp size is specified in the plan. Because the amount of track is to facilitate easy relocation of the luminaires to accommodate changes in the display of merchandise rather than to accommodate a large number of luminaires, the entire length will be supplied by a single 20-ampere, 120-volt branch circuit. What is the minimum calculated load associated with the track lighting that must be added to the service or feeder supplying this store?

#### Solution

According to the exception to 220.43(B), the minimum calculated load to be added to the service or feeder supplying this track light installation is calculated as follows:

$$20 \text{ A} \times 120 \text{ V} = 2400 \text{ VA}$$

The minimum load for the lighting track that is added to the service and/or feeder calculation is 2400 volt-amperes. This calculation could be further reduced where the track is supplied through a supplementary overcurrent protective device(s) having a current rating less than 20 amperes.

### 220.44 Receptacle Loads — Other Than Dwelling Units

Receptacle loads calculated in accordance with 220.14(H) and (I) shall be permitted to be made subject to the demand factors given in Table 220.42 or Table 220.44.

**TABLE 220.44 Demand Factors for Non-Dwelling Receptacle Loads**

Portion of Receptacle Load to Which Demand Factor Applies (Volt-Amperes)	Demand Factor (%)
First 10 kVA or less at	100
Remainder over 10 kVA at	50

Section 220.44 permits receptacle loads calculated at not more than 180 volt-amperes per strap to be computed by either of the following methods:

1. The receptacle loads are added to the lighting load. The demand factors (if applicable) in Table 220.12 are then applied to the combined load.
2. The receptacle loads are calculated (without the lighting load) with demand factors from Table 220.44 applied.

### 220.50 Motors

Motor loads shall be calculated in accordance with 430.24, 430.25, and 430.26 and with 440.6 for hermetic refrigerant motor compressors.

### 220.51 Fixed Electric Space Heating

Fixed electric space-heating loads shall be calculated at 100 percent of the total connected load. However, in no case shall a feeder or service load current rating be less than the rating of the largest branch circuit supplied.

*Exception: Where reduced loading of the conductors results from units operating on duty-cycle, intermittently, or from all units not operating at the same time, the authority having jurisdiction may grant permission for feeder and service conductors to have an ampacity less than 100 percent, provided the conductors have an ampacity for the load so determined.*

### 220.52 Small-Appliance and Laundry Loads — Dwelling Unit

**(A) Small-Appliance Circuit Load.** In each dwelling unit, the load shall be calculated at 1500 volt-amperes for each 2-wire small-appliance branch circuit as covered by 210.11(C)(1). Where the load is subdivided through two or more feeders, the calculated load for each shall include not less than 1500 volt-amperes for each 2-wire small-appliance branch circuit. These loads shall be permitted to be included with the general lighting load and subjected to the demand factors provided in Table 220.42.

*Exception: The individual branch circuit permitted by 210.52(B)(1), Exception No. 2, shall be permitted to be excluded from the calculation required by 220.52.*

See the commentary following 210.52(B) regarding required receptacle outlets for small-appliance branch circuits.

**(B) Laundry Circuit Load.** A load of not less than 1500 volt-amperes shall be included for each 2-wire laundry branch circuit installed as covered by 210.11(C)(2). This load shall be permitted to be included with the general lighting load and subjected to the demand factors provided in Table 220.42.

In each dwelling unit, the feeder load is required to be calculated at 1500 volt-amperes for each of the two or more (2-wire) small-appliance branch circuits and at 1500 volt-amperes for each (2-wire) laundry branch circuit. Where additional small-appliance and laundry branch circuits are provided, they also are calculated at 1500 volt-amperes per circuit. These loads are permitted to be totaled and then added to the general lighting load. The demand factors in Table 220.42 can then be applied to the combined total load of the small-appliance branch circuits, the laundry branch circuit, and the general lighting from Table 220.12.

### 220.53 Appliance Load — Dwelling Unit(s)

It shall be permissible to apply a demand factor of 75 percent to the nameplate rating load of four or more appliances fastened in place, other than electric ranges, clothes dryers, space-heating equipment, or air-conditioning equipment, that are served by the same feeder or service in a one-family, two-family, or multifamily dwelling.

For appliances fastened in place (other than ranges, clothes dryers, and space-heating and air-conditioning equipment), feeder capacity must be provided for the sum of these loads; for a total load of four or more such appliances, a demand factor of 75 percent is permitted by 220.53. See Table 430.248 for the full-load current, in amperes, for single-phase ac motors, in accordance with 220.50.

#### Calculation Example

Determine the feeder capacity needed for a 120/240-volt fastened-in-place appliance load in a dwelling unit for the following:

Appliance	Rating	Load
Water heater	4000 W, 240 V	4000 VA
Kitchen disposal	½ hp, 120 V	1176 VA
Dishwasher	1200 W, 120 V	1200 VA
Furnace motor	¼ hp, 120 V	696 VA
Attic fan	¼ hp, 120 V	696 VA
Water pump	½ hp, 240 V	1176 VA

#### Solution

STEP 1. Calculate the total of the six fastened-in-place appliances:

$$\begin{aligned}\text{Total load} &= 4000 \text{ VA} + 1176 \text{ VA} + 1200 \text{ VA} + 696 \text{ VA} \\ &\quad + 696 \text{ VA} + 1176 \text{ VA} \\ &= 8944 \text{ VA}\end{aligned}$$

STEP 2. Because the load is for more than four appliances, apply a demand factor of 75 percent:

$$8944 \text{ VA} \times 0.75 = 6708 \text{ VA}$$

Thus, 6708 volt-amperes is the load to be added to the other determined loads for calculating the size of service and feeder conductors.

### 220.54 Electric Clothes Dryers — Dwelling Unit(s)

The load for household electric clothes dryers in a dwelling unit(s) shall be either 5000 watts (volt-amperes) or the nameplate rating, whichever is larger, for each dryer served. The use of the demand factors in Table 220.54 shall be permitted. Where two or more single-phase dryers are supplied by a 3-phase, 4-wire feeder or service, the total load shall be calculated on the basis of twice the maximum number connected between any two phases. Kilovolt-amperes (kVA) shall be considered equivalent to kilowatts (kW) for loads calculated in this section.

**TABLE 220.54 Demand Factors for Household Electric Clothes Dryers**

Number of Dryers	Demand Factor (%)
1–4	100
5	85
6	75
7	65
8	60
9	55
10	50
11	47
12–23	47% minus 1% for each dryer exceeding 11
24–42	35% minus 0.5% for each dryer exceeding 23
43 and over	25%

The use of demand factors is permitted but not required by 220.54, because the *NEC* does not prohibit applying the full load of all dryers to a service and/or feeder calculation. However, this method is not necessary or practical, and experience has demonstrated that the use of the Table 220.54 demand factors provides sufficient capacity in the service for dryer loads. It is unlikely that all dryers will be in operation simultaneously, and Table 220.54 was developed based on utility demand that proves this point.

According to 220.54, the minimum load to be used is the larger of either 5000 VA or the nameplate rating of the dryer. In the following Calculation Example, the nameplate rating of 5500 VA (watts) is used. In addition, because of the supply system characteristics, calculation is a little different from simply adding the total rating of all dryers and applying the appropriate demand factor. The load of 10 single-phase dryers will be distributed across a 3-phase supply system.

#### Calculation Example

Assuming the load of 10 single-phase dryers is connected as evenly as possible to the 3-phase system (3 dryers connected between phases A and B, 3 dryers connected between phases B and C, and 4 dryers connected between phases A and C), the maximum number of dryers connected between any two phases is 4.

#### Solution

STEP 1. Twice the maximum number of dryers connected between any two phases is used as the basis for calculating the demand load:

$$4 \text{ dryers} \times 2 = 8 \text{ dryers}$$

60% demand from Table 220.54

$$5500 \text{ VA} \times 8 \times 0.6 = 26,400 \text{ VA}$$

(connected between two phases of the 3-phase system)

$$26,400 \text{ VA} \div 2 = 13,200 \text{ VA per phase load}$$

3-phase dryer load on service:

$$13,200 \text{ VA} \times 3 = 39,600 \text{ VA}$$

Dryer load on each of the ungrounded service or feeder conductors:

$$39,600 \text{ VA} \div (208 \text{ V} \times 1.732) = 110 \text{ A}$$

STEP 2. For the grounded (neutral) service or feeder conductor, 220.61(B)(1) permits a 70 percent demand to be applied to the demand load of the ungrounded conductors:

$$39,600 \text{ VA} \times 0.70 = 27,720 \text{ VA}$$

Dryer load on the grounded (neutral) service or feeder conductor:

$$27,720 \text{ VA} \div (208 \text{ V} \times 1.732) = 77 \text{ A}$$

Dryer load without applying the 220.54 demand factor:

3-phase dryer load:

$$5500 \text{ VA} \times 10 = 55,000 \text{ VA}$$

$$55,000 \text{ VA} \div (208 \text{ V} \times 1.732) = 153 \text{ A}$$

If the service and feeder load for this multifamily dwelling is calculated using the optional calculation for multifamily dwellings from Part IV of Article 220, the dryer load is not subject to an individual demand factor as required by the Part III calculation. Instead, the calculation performed in accordance with 220.84 totals all of the loads in an individual dwelling unit to arrive at a total “connected load.” The nameplate rating of the dryer and other appliance loads are part of a total load determined using 220.84(C)(1) through (C)(5). This connected load is then subjected to a single demand factor from Table 220.84 based on the total number of dwelling units served by a set of service or feeder conductors. For a set of conductors serving 10 dwelling units, the

demand factor is 43 percent. The dryer load determined by the optional calculation is as follows:

$$5500 \text{ VA} \times 10 \times 0.43 = 23,650 \text{ VA of dryer load}$$

$$23,650 \div (208 \text{ V} \times 1.732) = 66 \text{ A of 3-phase dryer load}$$

The load to be applied to the grounded service or feeder conductor can be calculated using the demand permitted by 220.61(B)(1).

The optional calculation can be used, provided all of the conditions specified in 220.84(A)(1) through (A)(3) are met. Otherwise, the calculation for the multifamily dwelling is

performed in accordance with the requirements of Part III of Article 220.

### 220.55 Electric Ranges and Other Cooking Appliances — Dwelling Unit(s)

The load for household electric ranges, wall-mounted ovens, counter-mounted cooking units, and other household cooking appliances individually rated in excess of  $1\frac{3}{4}$  kW shall be permitted to be calculated in accordance with Table 220.55. Kilo-volt-amperes (kVA) shall be considered equivalent to kilowatts (kW) for loads calculated under this section.

**TABLE 220.55 Demand Factors and Loads for Household Electric Ranges, Wall-Mounted Ovens, Counter-Mounted Cooking Units, and Other Household Cooking Appliances over  $1\frac{3}{4}$  kW Rating (Column C to be used in all cases except as otherwise permitted in Note 3.)**

Number of Appliances	Demand Factor (%) (See Notes)		Column C Maximum Demand (kW) (See Notes) (Not over 12 kW Rating)
	Column A (Less than $3\frac{1}{2}$ kW Rating)	Column B ( $3\frac{1}{2}$ kW through $8\frac{3}{4}$ kW Rating)	
1	80	80	8
2	75	65	11
3	70	55	14
4	66	50	17
5	62	45	20
6	59	43	21
7	56	40	22
8	53	36	23
9	51	35	24
10	49	34	25
11	47	32	26
12	45	32	27
13	43	32	28
14	41	32	29
15	40	32	30
16	39	28	31
17	38	28	32
18	37	28	33
19	36	28	34
20	35	28	35
21	34	26	36
22	33	26	37
23	32	26	38
24	31	26	39
25	30	26	40
26–30	30	24	15 kW + 1 kW for each range
31–40	30	22	
41–50	30	20	25 kW + $\frac{3}{4}$ kW for each range
51–60	30	18	
61 and over	30	16	

**TABLE 220.55** *Continued***Notes:**

1. Over 12 kW through 27 kW ranges all of same rating. For ranges individually rated more than 12 kW but not more than 27 kW, the maximum demand in Column C shall be increased 5 percent for each additional kilowatt of rating or major fraction thereof by which the rating of individual ranges exceeds 12 kW.

For household electric ranges and other cooking appliances, the size of the conductors must be determined by the rating of the range. According to Table 220.55, for one range rated 12 kW or less, the maximum demand load is 8 kW (8 kVA per 220.55), and 8 AWG copper

conductors with 60°C insulation would suffice. Note that 210.19(A)(3) does not permit the branch-circuit rating of a circuit supplying household ranges with a nameplate rating of 8¾ kW to be less than 40 amperes.

2. Over 8¾ kW through 27 kW ranges of unequal ratings. For ranges individually rated more than 8¾ kW and of different ratings, but none exceeding 27 kW, an average value of rating shall be calculated by adding together the ratings of all ranges to obtain the total connected load (using 12 kW for any range rated less than 12 kW) and dividing by the total number of ranges. Then the maximum demand in Column C shall be increased 5 percent for each kilowatt or major fraction thereof by which this average value exceeds 12 kW.

Note 2 to Table 220.55 provides for ranges larger than 8¾ kW. Note 4 covers installations where the circuit supplies multiple cooking components, which are combined and treated as a single range.

3. Over 1¾ kW through 8¾ kW. In lieu of the method provided in Column C, it shall be permissible to add the nameplate ratings of all household cooking appliances rated more than 1¾ kW but not more than 8¾ kW and multiply the sum by the demand factors specified in Column A or Column B for the given number of appliances. Where the rating of cooking appliances falls under both Column A and Column B, the demand factors for each column shall be applied to the appliances for that column, and the results added together.

The branch-circuit load for one range is permitted to be computed by using either the nameplate rating of the appliance or Table 220.55. If a single branch circuit supplies a counter-mounted cooking unit and not more than two wall-mounted ovens, all of which are located in the same room, the nameplate ratings of these appliances can be added and the total treated as the equivalent of one range, according to Note 4 of Table 220.55.

**Calculation Example**

Calculate the load for a single branch circuit that supplies the following cooking units:

- One counter-mounted cooking unit with rating of 8 kW
- One wall-mounted oven with rating of 7 kW
- A second wall-mounted oven with rating of 6 kW

**Solution**

STEP 1. The combined cooking appliances can be treated as one range, according to Note 4 of Table 220.55. In Table 220.55, find the maximum demand for one range not over 12 kW, which is 8 kW (from Column C).

STEP 2. According to Note 1 in Table 220.55, for ranges that are over 12 kW but not more than 27 kW, the maximum demand in Column C

(8 kW) is increased 5 percent for each kW that exceeds 12 kW. Determine the additional kilowatts:

$$\begin{aligned}\text{Combined unit rating} &= 8 \text{ kW} + 7 \text{ kW} + 6 \text{ kW} \\ &= 21 \text{ kW}\end{aligned}$$

$$\text{Additional kW} = 21 \text{ kW} - 12 \text{ kW} = 9 \text{ kW}$$

STEP 3. Calculate by how much the maximum load in Column C in Table 220.55 must be increased for the combined appliances:

$$\begin{aligned}\text{Increase} &= 5\% \text{ per kW} \times 9 \text{ kW} = 45\% \\ &= 0.45 \times 8 \text{ kW} = 3.6 \text{ kW}\end{aligned}$$

STEP 4. Calculate the total load in amperes, as follows:

$$\begin{aligned}\text{Total load} &= 8 \text{ kW} + 3.6 \text{ kW} = 11.6 \text{ kW} \\ &= 11,600 \text{ W} = 11,600 \text{ VA} \\ &= \frac{11,600 \text{ VA}}{240 \text{ V}} \\ &= 48.3 \text{ or } 48 \text{ A}\end{aligned}$$

4. Branch-Circuit Load. It shall be permissible to calculate the branch-circuit load for one range in accordance with Table 220.55. The branch-circuit load for one wall-mounted oven or one counter-mounted cooking unit shall be the nameplate rating of the appliance. The branch-circuit load for a counter-mounted cooking unit and not more than two wall-mounted ovens, all supplied from a single branch circuit and located in the same room, shall be calculated by adding the nameplate rating of the individual appliances and treating this total as equivalent to one range.

5. This table shall also apply to household cooking appliances rated over 1¾ kW and used in instructional programs.

(continues)

TABLE 220.55 *Continued*

The nameplate ratings of all household cooking appliances rated more than 1¼ kW but not more than 8¾ kW may be added and the sum multiplied by the demand factor specified in Column A or B of Table 220.55 for the given number of appliances. For feeder demand factors for other than dwelling units — that is, commercial electric cooking equipment, dishwasher booster heaters, water heaters, and so on — see Table 220.56.

The demand factors in the *Code* are based on the diversified use of household appliances, because it is unlikely that all appliances will be used simultaneously or that all cooking units and the oven of a range will be at maximum heat for any length of time.

Where two or more single-phase ranges are supplied by a 3-phase, 4-wire feeder or service, the total load shall be calculated on the basis of twice the maximum number connected between any two phases.

Counter-mounted cooking appliances have a smaller rating than that of a full-size range with an oven. The load for a counter-mounted cooking appliance is typically covered by either Column A or by Column B in Table 220.55. Where counter-mounted cooking appliances like the one pictured in Exhibit 220.6 are used with a separate wall oven, it is permissible to run a single branch circuit, sized according to Note 4 to Table 220.55, to the kitchen and supply each with branch-circuit tap conductors installed as specified in 210.19(A)(3), Exception No. 1.

EXHIBIT 220.6 A counter-mounted cooking appliance installed in a dwelling-unit kitchen.

- Informational Note No. 1: See Example D5(A) in Informative Annex D.
- Informational Note No. 2: See Table 220.56 for commercial cooking equipment.
- Informational Note No. 3: See the examples in Informative Annex D.

220.56 Kitchen Equipment — Other Than Dwelling Unit(s)

It shall be permissible to calculate the load for commercial electric cooking equipment, dishwasher booster heaters, water heaters, and other kitchen equipment in accordance with Table 220.56. These demand factors shall be applied to all equipment that has either thermostatic control or intermittent use as kitchen equipment. These demand factors shall not apply to space-heating, ventilating, or air-conditioning equipment.

However, in no case shall the feeder or service calculated load be less than the sum of the largest two kitchen equipment loads.

TABLE 220.56 Demand Factors for Kitchen Equipment — Other Than Dwelling Unit(s)

Number of Units of Equipment	Demand Factor (%)
1	100
2	100
3	90
4	80
5	70
6 and over	65

Because commercial electric cooking and other kitchen equipment is used more intensively and for longer periods of time than electric cooking equipment in a dwelling unit, the demand factors in Table 220.56 do not provide a comparable demand to that permitted for dwelling unit cooking appliances until there are six or more commercial appliances. The demand factors in Table 220.56 can be applied to a combination of cooking, dishwashing, water heating, and other type commercial kitchen appliances, and the combined total allows a deeper demand factor to be applied. Thermostatically controlled electric cooking appliances such as the one shown in Exhibit 220.7 are permitted, but not required, to have the demand applied to the appliance nameplate rating. Commercial electric cooking appliances are sometimes used continuously from morning until night,

**EXHIBIT 220.7** Electrically powered cooking/heating appliance with thermostatic control in a commercial kitchen. Electric appliance loads on feeder and service conductors supplying commercial and institutional kitchens are permitted to be calculated using the demand factors specified in Table 220.56. (Courtesy of the International Association of Electrical Inspectors)

thus the demand factors for commercial applications are not as generous as those permitted for dwelling units.

## 220.60 Noncoincident Loads

Where it is unlikely that two or more noncoincident loads will be in use simultaneously, it shall be permissible to use only the largest load(s) that will be used at one time for calculating the total load of a feeder or service.

## 220.61 Feeder or Service Neutral Load

**(A) Basic Calculation.** The feeder or service neutral load shall be the maximum unbalance of the load determined by this article. The maximum unbalanced load shall be the maximum net calculated load between the neutral conductor and any one ungrounded conductor.

*Exception: For 3-wire, 2-phase or 5-wire, 2-phase systems, the maximum unbalanced load shall be the maximum net calculated load between the neutral conductor and any one ungrounded conductor multiplied by 140 percent.*

**(B) Permitted Reductions.** A service or feeder supplying the following loads shall be permitted to have an additional demand factor of 70 percent applied to the amount in 220.61(B)(1) or portion of the amount in 220.61(B)(2) determined by the basic calculation:

- (1) A feeder or service supplying household electric ranges, wall-mounted ovens, counter-mounted cooking units,

and electric dryers, where the maximum unbalanced load has been determined in accordance with Table 220.55 for ranges and Table 220.54 for dryers

- (2) That portion of the unbalanced load in excess of 200 amperes where the feeder or service is supplied from a 3-wire dc or single-phase ac system; or a 4-wire, 3-phase, 3-wire, 2-phase system; or a 5-wire, 2-phase system

**(C) Prohibited Reductions.** There shall be no reduction of the neutral or grounded conductor capacity applied to the amount in 220.61(C)(1), or portion of the amount in (C)(2), from that determined by the basic calculation:

- (1) Any portion of a 3-wire circuit consisting of 2 ungrounded conductors and the neutral conductor of a 4-wire, 3-phase, wye-connected system
- (2) That portion consisting of nonlinear loads supplied from a 4-wire, wye-connected, 3-phase system

Informational Note No. 1: See Examples D1(a), D1(b), D2(b), D4(a), and D5(a) in Informative Annex D.

Informational Note No. 2: A 3-phase, 4-wire, wye-connected power system used to supply power to nonlinear loads may necessitate that the power system design allow for the possibility of high harmonic neutral-conductor currents.

Section 220.61 describes the basis for calculating the neutral load of feeders or services as the maximum unbalanced load that can occur between the neutral and any other ungrounded conductor. For a household electric range or clothes dryer, the maximum unbalanced load may be assumed to be 70 percent, so the neutral may be sized on that basis. Section 220.61(B) permits the reduction of the feeder neutral conductor size under specific conditions of use, and 220.61(C)(1) and (C)(2) cite a circuit arrangement and a load characteristic as applications where it is not permitted to reduce the capacity of a neutral or grounded conductor of a feeder or service.

If the system also supplies nonlinear loads such as electric-discharge lighting, including fluorescent and HID, or data-processing or similar equipment, the neutral is considered a current-carrying conductor if the load of the electric-discharge lighting, data-processing, or similar equipment on the feeder neutral consists of more than half the total load, in accordance with 310.15(B)(5)(c). Electric-discharge lighting and data-processing equipment may have harmonic currents in the neutral that may exceed the load current in the ungrounded conductors. Informational Note No. 2 cautions designers and installers to be cognizant of harmonic contribution and include provisions in the electrical system design to accommodate the harmonic load imposed on neutral conductors. In some instances, the neutral current may exceed the current in the phase conductors. See the commentary following 310.15(B)(5)(c) regarding neutral conductor ampacity.

## IV. Optional Feeder and Service Load Calculations

### 220.80 General

Optional feeder and service load calculations shall be permitted in accordance with Part IV.

### 220.82 Dwelling Unit

**(A) Feeder and Service Load.** This section applies to a dwelling unit having the total connected load served by a single 120/240-volt or 208Y/120-volt set of 3-wire service or feeder conductors with an ampacity of 100 or greater. It shall be permissible to calculate the feeder and service loads in accordance with this section instead of the method specified in Part III of this article. The calculated load shall be the result of adding the loads from 220.82(B) and (C). Feeder and service-entrance conductors whose calculated load is determined by this optional calculation shall be permitted to have the neutral load determined by 220.61.

The optional calculation method in 220.82 is permitted only if the service-entrance or feeder conductors have an ampacity of at least 100 amperes. It applies to a single dwelling unit, whether it is a separate building or located in a multi-family dwelling. See Article 100 for the definition of *dwelling unit*.

Examples of the optional calculation for a dwelling unit are given in Examples D2(a), D2(b), D2(c), and D4(b) of Informative Annex D.

**(B) General Loads.** The general calculated load shall be not less than 100 percent of the first 10 kVA plus 40 percent of the remainder of the following loads:

- (1) 33 volt-amperes/m<sup>2</sup> or 3 volt-amperes/ft<sup>2</sup> for general lighting and general-use receptacles. The floor area for each floor shall be calculated from the outside dimensions of the dwelling unit. The calculated floor area shall not include open porches, garages, or unused or unfinished spaces not adaptable for future use.
- (2) 1500 volt-amperes for each 2-wire, 20-ampere small-appliance branch circuit and each laundry branch circuit covered in 210.11(C)(1) and (C)(2).
- (3) The nameplate rating of the following:
  - a. All appliances that are fastened in place, permanently connected, or located to be on a specific circuit
  - b. Ranges, wall-mounted ovens, counter-mounted cooking units
  - c. Clothes dryers that are not connected to the laundry branch circuit specified in item (2)
  - d. Water heaters

Section 220.82(B) specifies the loads for appliances that may not be fastened in place but that may be permanently connected or on a specific circuit, such as clothes dryers, dishwashers, and freezers.

- (4) The nameplate ampere or kVA rating of all permanently connected motors not included in item (3).

**(C) Heating and Air-Conditioning Load.** The largest of the following six selections (load in kVA) shall be included:

- (1) 100 percent of the nameplate rating(s) of the air conditioning and cooling.
- (2) 100 percent of the nameplate rating(s) of the heat pump when the heat pump is used without any supplemental electric heating.
- (3) 100 percent of the nameplate rating(s) of the heat pump compressor and 65 percent of the supplemental electric heating for central electric space-heating systems. If the heat pump compressor is prevented from operating at the same time as the supplementary heat, it does not need to be added to the supplementary heat for the total central space heating load.

Where the heat pump compressor and supplemental heating operate at the same time, 100 percent of the compressor load plus 65 percent of the supplemental heating load is treated as the central space heating load. If the equipment operates such that the compressor cannot operate concurrently with the supplemental heating, the central space heating load is required to be based on only 65 percent of the supplemental heating load.

- (4) 65 percent of the nameplate rating(s) of electric space heating if less than four separately controlled units.
- (5) 40 percent of the nameplate rating(s) of electric space heating if four or more separately controlled units.
- (6) 100 percent of the nameplate ratings of electric thermal storage and other heating systems where the usual load is expected to be continuous at the full nameplate value. Systems qualifying under this selection shall not be calculated under any other selection in 220.82(C).

For loads that do not operate simultaneously, 220.60 permits the total load to be calculated based on the largest load being considered. Similarly, 220.82(C) requires that only the largest of the six choices needs to be included in the feeder or service calculation. Examples of calculations using air conditioning and heating are found in Informative Annex D, Examples D2(a), (b), and (c).

**220.83 Existing Dwelling Unit**

This section shall be permitted to be used to determine if the existing service or feeder is of sufficient capacity to serve additional loads. Where the dwelling unit is served by a 120/240-volt or 208Y/120-volt, 3-wire service, it shall be permissible to calculate the total load in accordance with 220.83(A) or (B).

**(A) Where Additional Air-Conditioning Equipment or Electric Space-Heating Equipment Is Not to Be Installed.**

The following percentages shall be used for existing and additional new loads.

Load (kVA)	Percent of Load
First 8 kVA of load at	100
Remainder of load at	40

Load calculations shall include the following:

- (1) General lighting and general-use receptacles at 33 volt-amperes/m<sup>2</sup> or 3 volt-amperes/ft<sup>2</sup> as determined by 220.12
- (2) 1500 volt-amperes for each 2-wire, 20-ampere small-appliance branch circuit and each laundry branch circuit covered in 210.11(C)(1) and (C)(2)
- (3) The nameplate rating of the following:
  - a. All appliances that are fastened in place, permanently connected, or located to be on a specific circuit
  - b. Ranges, wall-mounted ovens, counter-mounted cooking units
  - c. Clothes dryers that are not connected to the laundry branch circuit specified in item (2)
  - d. Water heaters

**(B) Where Additional Air-Conditioning Equipment or Electric Space-Heating Equipment Is to Be Installed.**

The following percentages shall be used for existing and additional new loads. The larger connected load of air-conditioning or space-heating, but not both, shall be used.

Load	Percent of Load
Air-conditioning equipment	100
Central electric space heating	100
Less than four separately controlled space-heating units	100
First 8 kVA of all other loads	100
Remainder of all other loads	40

Other loads shall include the following:

- (1) General lighting and general-use receptacles at 33 volt-amperes/m<sup>2</sup> or 3 volt-amperes/ft<sup>2</sup> as determined by 220.12

- (2) 1500 volt-amperes for each 2-wire, 20-ampere small-appliance branch circuit and each laundry branch circuit covered in 210.11(C)(1) and (C)(2)
- (3) The nameplate rating of the following:
  - a. All appliances that are fastened in place, permanently connected, or located to be on a specific circuit
  - b. Ranges, wall-mounted ovens, counter-mounted cooking units
  - c. Clothes dryers that are not connected to the laundry branch circuit specified in (2)
  - d. Water heaters

The optional methods described in 220.83(A) and (B) allow an additional load to be supplied by an existing service.

**Calculation Example**

An existing dwelling unit is served by a 100-ampere service. An additional load of a single 5-kVA, 240-volt air-conditioning unit is to be installed. Because the existing load does not contain heating or air-conditioning equipment, the existing load is calculated according to 220.83(A). The load of the existing dwelling unit consists of the following:

General lighting:

$$24 \text{ ft} \times 40 \text{ ft} = 960 \text{ ft}^2 \times \text{VA per ft}^2 \quad 2,880 \text{ VA}$$

$$\text{Small-appliance circuits: } 3 \times 1500 \text{ VA} \quad 4,500 \text{ VA}$$

$$\text{Laundry circuit at } 1500 \text{ VA} \quad 1,500 \text{ VA}$$

$$\text{Electric range rated } 10.5 \text{ kW} \quad 10,500 \text{ VA}$$

$$\text{Electric water heater rated } 3.0 \text{ kW} \quad 3,000 \text{ VA}$$

$$\text{Total existing load} \quad 22,380 \text{ VA}$$

**Solution**

STEP 1. Following the requirements of 220.83(A), calculate the existing dwelling unit load before adding any equipment:

$$\text{First 8 kVA of load at } 100\% \quad 8,000 \text{ VA}$$

$$\text{Remainder of load at } 40\%:$$

$$22,380 \text{ VA} - 8,000 \text{ VA} = 14,380 \text{ VA} \times 40\% \quad 5,752 \text{ VA}$$

$$\text{Total load} \quad 13,752 \text{ VA}$$

(without air-conditioning equipment)

$$13,752 \text{ VA} \div 240 \text{ V} = 57.3 \text{ A}$$

STEP 2. Prepare a list of the existing and new loads of the dwelling unit.

General lighting:

$$24 \text{ ft} \times 40 \text{ ft} = 960 \text{ ft}^2 \times \text{VA per ft}^2 \quad 2,880 \text{ VA}$$

Small-appliance circuits:

$$3 \times 1500 \text{ VA} \quad 4,500 \text{ VA}$$

$$\text{Laundry circuit at } 1500 \text{ VA} \quad 1,500 \text{ VA}$$

$$\text{Electric range rated } 10.5 \text{ kW} \quad 10,500 \text{ VA}$$

$$\text{Electric water heater rated } 3.0 \text{ kW} \quad 3,000 \text{ VA}$$

$$\text{Added air-conditioning equipment} \quad 5,000 \text{ VA}$$

$$\text{Total new load} \quad 27,380 \text{ VA}$$

STEP 3. Following the requirements in 220.83(B), calculate the dwelling unit total load after adding any new equipment:

First 8 kVA of other load at 100%	8,000 VA
Remainder of other load at 40%:	
22,380 VA – 8,000 VA = 14,380 VA × 40%	5,752 VA
100% of air-conditioning equipment	5,000 VA
Total load	18,752 VA
(with added air-conditioning equipment)	
18,752 VA ÷ 240 V = 78.13 or 78 A	

The additional load contributed by the added 5-kVA air conditioning does not exceed the allowable load permitted on a 100-ampere service.

## 220.84 Multifamily Dwelling

**(A) Feeder or Service Load.** It shall be permissible to calculate the load of a feeder or service that supplies three or more dwelling units of a multifamily dwelling in accordance with Table 220.84 instead of Part III of this article if all the following conditions are met:

- (1) No dwelling unit is supplied by more than one feeder.
- (2) Each dwelling unit is equipped with electric cooking equipment.

*Exception: When the calculated load for multifamily dwellings without electric cooking in Part III of this article exceeds that calculated under Part IV for the identical load plus electric cooking (based on 8 kW per unit), the lesser of the two loads shall be permitted to be used.*

According to 220.84(A)(2), each dwelling unit must be equipped with electric cooking equipment in order to use the load calculation method found in 220.84(A). The exception to 220.84(A)(2) permits load calculation for dwelling units that do not have electric cooking equipment, by using a simulated electric cooking equipment load of 8 kW per unit and comparing this calculated load to the load for the dwellings without electric cooking equipment calculated in accordance with Part III of Article 220 (commonly referred to as the “standard calculation”). Whichever of these calculations yields the smallest load is permitted to be used.

- (3) Each dwelling unit is equipped with either electric space heating or air conditioning, or both. Feeders and service conductors whose calculated load is determined by this optional calculation shall be permitted to have the neutral load determined by 220.61.

**(B) House Loads.** House loads shall be calculated in accordance with Part III of this article and shall be in addition

to the dwelling unit loads calculated in accordance with Table 220.84.

**TABLE 220.84 Optional Calculations — Demand Factors for Three or More Multifamily Dwelling Units**

Number of Dwelling Units	Demand Factor (%)
3–5	45
6–7	44
8–10	43
11	42
12–13	41
14–15	40
16–17	39
18–20	38
21	37
22–23	36
24–25	35
26–27	34
28–30	33
31	32
32–33	31
34–36	30
37–38	29
39–42	28
43–45	27
46–50	26
51–55	25
56–61	24
62 and over	23

The method of load calculation under 220.84 is optional and applies only where one service or feeder supplies the entire load of a dwelling unit. If all the stated conditions prevail, the optional calculations in 220.84 may be used instead of those in Part III of Article 220.

**(C) Calculated Loads.** The calculated load to which the demand factors of Table 220.84 apply shall include the following:

- (1) 33 volt-amperes/m<sup>2</sup> or 3 volt-amperes/ft<sup>2</sup> for general lighting and general-use receptacles
- (2) 1500 volt-amperes for each 2-wire, 20-ampere small-appliance branch circuit and each laundry branch circuit covered in 210.11(C)(1) and (C)(2)
- (3) The nameplate rating of the following:
  - a. All appliances that are fastened in place, permanently connected, or located to be on a specific circuit
  - b. Ranges, wall-mounted ovens, counter-mounted cooking units

- c. Clothes dryers that are not connected to the laundry branch circuit specified in item (2)
  - d. Water heaters
- (4) The nameplate ampere or kVA rating of all permanently connected motors not included in item (3)
- (5) The larger of the air-conditioning load or the fixed electric space-heating load

### 220.85 Two Dwelling Units

Where two dwelling units are supplied by a single feeder and the calculated load under Part III of this article exceeds that for three identical units calculated under 220.84, the lesser of the two loads shall be permitted to be used.

### 220.86 Schools

The calculation of a feeder or service load for schools shall be permitted in accordance with Table 220.86 in lieu of Part III of this article where equipped with electric space heating, air conditioning, or both. The connected load to which the demand factors of Table 220.86 apply shall include all of the interior and exterior lighting, power, water heating, cooking, other loads, and the larger of the air-conditioning load or space-heating load within the building or structure.

Feeders and service conductors whose calculated load is determined by this optional calculation shall be permitted to have the neutral load determined by 220.61. Where the building or structure load is calculated by this optional method, feeders within the building or structure shall have ampacity as permitted in Part III of this article; however, the ampacity of an individual feeder shall not be required to be larger than the ampacity for the entire building.

This section shall not apply to portable classroom buildings.

Many schools add small, portable classroom buildings. The air-conditioning load in these portable classrooms must comply with Article 440, and the lighting load must be considered continuous. The demand factors in Table 220.86 do not apply to portable classrooms, because those demand factors would decrease the feeder or service size to below that required for the connected continuous load.

**TABLE 220.86 Optional Method — Demand Factors for Feeders and Service Conductors for Schools**

Connected Load		Demand Factor (Percent)
First 33 VA/m <sup>2</sup>	(3 VA/ft <sup>2</sup> ) at	100
Plus,		
Over 33 through 220 VA/m <sup>2</sup>	(3 through 20 VA/ft <sup>2</sup> ) at	75
Plus,		
Remainder over 220 VA/m <sup>2</sup>	(20 VA/ft <sup>2</sup> ) at	25

Table 220.86 provides a series of demand increments that are permitted to be applied to the initial calculated load for service or feeder conductors supplying the total load of a school building in lieu of the “standard” calculation covered in Part III of Article 220. The incremental Steps of Table 220.86 are based on more significant reductions of the total load as the load per square foot increases. Any portion of the load exceeding 20 VA per square foot is permitted to have a 25 percent demand factor applied. This approach is similar in concept to that applied to dwellings in Table 220.42, except that the demands in Table 220.86 apply to the entire load of the building, not just the general lighting load.

To use Table 220.86, the school must have electric space heating or air conditioning, or both. The loads to which the demand factors can be applied are specified in 220.86. Feeder conductors that do not supply the entire load of the building or structure are to be calculated in accordance with Part III of Article 220. Feeder conductors supplying subdivided building loads are not required to be larger than the service or feeder conductors that supply the entire building or structure load.

To apply Table 220.86 the initial calculation based on all of the loads specified in 220.86 first has to be performed. Once this calculation has been made, the demand factors can be applied as indicated in the table.

#### Calculation Example 1

Calculate the overall demand factor for a 100,000 ft<sup>2</sup> school building (based on outside dimensions and the number of stories) using Table 220.86.

#### Solution

The initial calculated load based on 220.86 is 1.5 mVA, or 1,500,000 VA.

$$1.15 \text{ mVA}/100,000 \text{ ft}^2 = 11.5 \text{ VA/ft}^2$$

First 3 VA/ft<sup>2</sup> at 100%:

$$3 \text{ VA} \times 100,000 = 300 \text{ kVA}$$

Remaining 8.5 VA at 75%:

$$8.5 \text{ VA} \times 100,000 \times 0.75 = 637.5 \text{ kVA}$$

Demand load for the school:

$$300 \text{ kVA} + 637.5 \text{ kVA} = 937.5 \text{ kVA}$$

$$937,500 \text{ VA}/1,500,000 \text{ VA} = 0.82$$

or 82% overall demand factor on entire building load obtained using Table 220.86 demand factors.

#### Calculation Example 2

Now calculate the overall demand factor for the same 100,000 ft<sup>2</sup> school building if the initial calculated load is 2.5 mVA (2,500,000).

Solution

$2.5 \text{ VA}/100,000 \text{ ft}^2 = 25 \text{ VA}/\text{ft}^2$   
First  $3 \text{ VA}/\text{ft}^2$  at 100%:  
 $3 \text{ VA} \times 100,000 = 300 \text{ kVA}$   
Next  $17 \text{ VA}/\text{ft}^2$  at 75%:  
 $17 \text{ VA} \times 100,000 \times 0.75 = 1,275 \text{ kVA}$   
Remaining  $5 \text{ VA}/\text{ft}^2$  at 25%:  
 $5 \times 100,000 \times 0.25 = 125 \text{ kVA}$   
Demand load for the school:  
 $300 + 1,275 + 125 = 1700 \text{ kVA (1.7 mVA)}$   
 $1.7 \text{ mVA}/2.5 \text{ mVA} = 0.68$   
or 68% overall demand factor on entire building load obtained using Table 220.86 demand factors.

220.87 Determining Existing Loads

The calculation of a feeder or service load for existing installations shall be permitted to use actual maximum demand to determine the existing load under all of the following conditions:

- (1) The maximum demand data is available for a 1-year period.

*Exception: If the maximum demand data for a 1-year period is not available, the calculated load shall be permitted to be based on the maximum demand (measure of average power demand over a 15-minute period) continuously recorded over a minimum 30-day period using a recording ammeter or power meter connected to the highest loaded phase of the feeder or service, based on the initial loading at the start of the recording. The recording shall reflect the maximum demand of the feeder or service by being taken when the building or space is occupied and shall include by measurement or calculation the larger of the heating or cooling equipment load, and other loads*

*that may be periodic in nature due to seasonal or similar conditions.*

- (2) The maximum demand at 125 percent plus the new load does not exceed the ampacity of the feeder or rating of the service.
- (3) The feeder has overcurrent protection in accordance with 240.4, and the service has overload protection in accordance with 230.90.

Additional loads may be connected to existing services and feeders under the following conditions:

- 1. The maximum demand kVA data for a minimum 1-year period (or the 30-day alternative method from the exception) is available.
- 2. The installation complies with 220.87(2) and 220.87(3).

220.88 New Restaurants

Calculation of a service or feeder load, where the feeder serves the total load, for a new restaurant shall be permitted in accordance with Table 220.88 in lieu of Part III of this article.

The overload protection of the service conductors shall be in accordance with 230.90 and 240.4.

Feeder conductors shall not be required to be of greater ampacity than the service conductors.

Service or feeder conductors whose calculated load is determined by this optional calculation shall be permitted to have the neutral load determined by 220.61.

The demand factors in 220.88 recognize the effects of load diversity that are typical of restaurant occupancies. It also recognizes the amount of continuous loads as a percentage of the total connected load.

The National Restaurant Association, the Edison Electric Institute, and the Electric Power Research Institute based the data for 220.88 on load studies of 262 restaurants. These studies showed that the demand factors were lower

TABLE 220.88 Optional Method — Permitted Load Calculations for Service and Feeder Conductors for New Restaurants

Total Connected Load (kVA)	All Electric Restaurant Calculated Loads (kVA)	Not All Electric Restaurant Calculated Loads (kVA)
0–200	80%	100%
201–325	10% (amount over 200) + 160.0	50% (amount over 200) + 200.0
326–800	50% (amount over 325) + 172.5	45% (amount over 325) + 262.5
Over 800	50% (amount over 800) + 410.0	20% (amount over 800) + 476.3

Note: Add all electrical loads, including both heating and cooling loads, to calculate the total connected load. Select the one demand factor that applies from the table, then multiply the total connected load by this single demand factor.

for restaurants with larger connected loads. Based on this information, the demand factors in Table 220.88 for restaurant loads were developed.

When using the optional calculation method for new restaurant loads, all of the electrical loads are added together including the heating and air-conditioning loads. The service or feeder size is calculated by applying the appropriate demand factor from Table 220.88 to the total load kVA.

#### Calculation Example 1

A new, all-electric restaurant has a total connected load of 348 kVA at 208Y/120 volts. Using Table 220.88, calculate the demand load and determine the size of the service-entrance conductors and the maximum-size overcurrent device for the service.

#### Solution

STEP 1. Use the value in Table 220.88 for a connected load of 348 kVA (Row 3, Column 2) to calculate the demand load for an all-electric restaurant:

$$\begin{aligned}\text{Demand load} &= 50\% \text{ of amount over } 325 \text{ kVA} \\ &+ 172.5 \text{ kVA} \\ &= 0.50 \times (348 \text{ kVA} - 325 \text{ kVA}) + 172.5 \text{ kVA} \\ &= (0.50 \times 23) + 172.5 \\ &= 11.5 + 172.5 \\ &= 184 \text{ kVA}\end{aligned}$$

STEP 2. Calculate the service size using the calculated demand load in Step 1:

$$\begin{aligned}\text{Service size} &= \frac{\text{kVA}_{\text{Demand load}} \times 1000}{\text{voltage} \sqrt{3}} \\ &= \frac{184 \text{ kVA} \times 1000}{208 \text{ V} \times \sqrt{3}} \\ &= 510.7 \text{ or } 511 \text{ A}\end{aligned}$$

STEP 3. Determine the size of the overcurrent device. The next larger standard-size overcurrent device is 600 amperes. The minimum size of the conductors must be adequate to handle the load, but 240.4(B) permits the next larger standard-rated overcurrent device to be used.

#### Calculation Example 2

A new restaurant has gas cooking appliances plus a total connected electrical load of 348 kVA at 208Y/120 volts. Calculate the demand load using Table 220.88 and the service size. Then determine the maximum-size overcurrent device for the service.

#### Solution

STEP 1. Calculate the demand load for a new restaurant using the value in Table 220.88 for a connected load of 348 kVA (Column 3, Row 3) as follows:

$$\begin{aligned}\text{Demand load} &= 45\% \text{ of amount over } 325 \text{ kVA} \\ &+ 262.5 \text{ kVA} \\ &= 0.45 \times (348 - 325) + 262.5 \\ &= (0.45 \times 23) + 262.5 \\ &= 10.35 + 262.5 \\ &= 272.85 \text{ kVA}\end{aligned}$$

STEP 2. Calculate the service size using the calculated demand load in Step 1.

$$\begin{aligned}\text{Service size} &= \frac{\text{kVA}_{\text{Demand load}} \times 1000}{\text{voltage} \sqrt{3}} \\ &= \frac{272.85 \text{ kVA} \times 1000}{208 \text{ V} \times \sqrt{3}} \\ &= 757.36 \text{ or } 757 \text{ A}\end{aligned}$$

STEP 3. Determine the size of the overcurrent device. The next higher standard rating for an overcurrent device, according to 240.6, is 800 amperes. Section 230.79 requires that the service disconnecting means have a rating that is not less than the calculated load (757 amperes). The minimum size of the conductors must be adequate to handle the load, but 240.4(B) permits the next larger standard-rated overcurrent device to be used.

## V. Farm Load Calculations

### 220.100 General

Farm loads shall be calculated in accordance with Part V.

### 220.102 Farm Loads — Buildings and Other Loads

(A) **Dwelling Unit.** The feeder or service load of a farm dwelling unit shall be calculated in accordance with the provisions for dwellings in Part III or IV of this article. Where the dwelling has electric heat and the farm has electric grain-drying systems, Part IV of this article shall not be used to calculate the dwelling load where the dwelling and farm loads are supplied by a common service.

(B) **Other Than Dwelling Unit.** Where a feeder or service supplies a farm building or other load having two or more separate branch circuits, the load for feeders, service conductors, and service equipment shall be calculated in accordance with demand factors not less than indicated in Table 220.102.

### 220.103 Farm Loads — Total

Where supplied by a common service, the total load of the farm for service conductors and service equipment shall be calculated in accordance with the farm dwelling unit load and demand factors specified in Table 220.103. Where there

**TABLE 220.102 Method for Calculating Farm Loads for Other Than Dwelling Unit**

Ampere Load at 240 Volts Maximum	Demand Factor (%)
The greater of the following: All loads that are expected to operate simultaneously, or 125 percent of the full load current of the largest motor, or First 60 amperes of the load	100
Next 60 amperes of all other loads	50
Remainder of other loads	25

is equipment in two or more farm equipment buildings or for loads having the same function, such loads shall be calculated in accordance with Table 220.102 and shall be permitted to be combined as a single load in Table 220.103 for calculating the total load.

**TABLE 220.103 Method for Calculating Total Farm Load**

Individual Loads Calculated in Accordance with Table 220.102	Demand Factor (%)
Largest load	100
Second largest load	75
Third largest load	65
Remaining loads	50

Note: To this total load, add the load of the farm dwelling unit calculated in accordance with Part III or IV of this article. Where the dwelling has electric heat and the farm has electric grain-drying systems, Part IV of this article shall not be used to calculate the dwelling load.

### 225.1 Scope

This article covers requirements for outside branch circuits and feeders run on or between buildings, structures, or poles on the premises; and electrical equipment and wiring for the supply of utilization equipment that is located on or attached to the outside of buildings, structures, or poles.

Article 225 provides requirements unique to the installation of feeders and branch circuits on the outside (overhead and underground) of buildings and structures. These circuits may be supplying specific items of electrical equipment or they may be the power supply to another building or struc-

ture. The power source for the outside feeders and/or branch circuits may be delivered to a site by a utility and subsequently distributed throughout a multibuilding industrial or institutional campus as feeder or branch circuits, the power source may be a separately derived system such as an emergency or standby system, or the power source may be a combination of the two. This article covers sources rated 600 volts, nominal or less and sources rated over 600 volts, nominal. These requirements are to be used in addition to the general requirements for branch circuits and feeders in Articles 210 and 215.

Informational Note: For additional information on wiring over 600 volts, see ANSI C2-2007, *National Electrical Safety Code*.

### 225.2 Definition

**Substation.** An enclosed assemblage of equipment (e.g., switches, circuit breakers, buses, and transformers) under the control of qualified persons, through which electric energy is passed for the purpose of switching or modifying its characteristics.

### 225.3 Other Articles

Application of other articles, including additional requirements to specific cases of equipment and conductors, is shown in Table 225.3.

## I. General

### 225.4 Conductor Covering

Where within 3.0 m (10 ft) of any building or structure other than supporting poles or towers, open individual (aerial) overhead conductors shall be insulated or covered. Conductors in cables or raceways, except Type MI cable, shall be of the rubber-covered type or thermoplastic type and, in wet locations, shall comply with 310.10(C). Conductors for festoon lighting shall be of the rubber-covered or thermoplastic type.

*Exception: Equipment grounding conductors and grounded circuit conductors shall be permitted to be bare or covered as specifically permitted elsewhere in this Code.*

The exception to 225.4 and Exception No. 2 to 250.184(A) (1) correlate to permit the use of the bare messenger wire of an overhead cable assembly as the grounded (neutral) conductor of an outdoor feeder circuit. In accordance with 250.32(B), Exception, a grounding electrode conductor connection to the grounded conductor is permitted at the load end of such outdoor overhead feeder circuits for existing

**TABLE 225.3 Other Articles**

installations. For new installations, an equipment grounding conductor is required to be included in the overhead feeder cable assembly and it is required by 250.32(B) to be connected to a grounding electrode system.

### 225.5 Size of Conductors 600 Volts, Nominal, or Less

The ampacity of outdoor branch-circuit and feeder conductors shall be in accordance with 310.15 based on loads as determined under 220.10 and Part III of Article 220.

### 225.6 Conductor Size and Support

**(A) Overhead Spans.** Open individual conductors shall not be smaller than the following:

- (1) For 600 volts, nominal, or less, 10 AWG copper or 8 AWG aluminum for spans up to 15 m (50 ft) in length, and 8 AWG copper or 6 AWG aluminum for a longer span unless supported by a messenger wire

- (2) For over 600 volts, nominal, 6 AWG copper or 4 AWG aluminum where open individual conductors, and 8 AWG copper or 6 AWG aluminum where in cable

The size limitation of copper and aluminum conductors for overhead spans specified in 225.6(A) is based on the need for adequate mechanical strength to support the weight of the conductors and to withstand wind, ice, and other similar conditions. Exhibit 225.1 illustrates overhead spans that are not messenger supported; that are run between buildings, structures, or poles; and that are 600 volts or less. If the conductors are supported on a messenger, the messenger cable provides the necessary mechanical strength. See 396.10 for wiring methods permitted to be messenger supported.

**EXHIBIT 225.1** Minimum sizes of conductors in overhead spans as specified by 225.6(A)(1) for 600 volts, nominal, or less.

**(B) Festoon Lighting.** Overhead conductors for festoon lighting shall not be smaller than 12 AWG unless the conductors are supported by messenger wires. In all spans exceeding 12 m (40 ft), the conductors shall be supported by messenger wire. The messenger wire shall be supported by strain insulators. Conductors or messenger wires shall not be attached to any fire escape, downspout, or plumbing equipment.

Article 100 defines festoon lighting as “a string of outdoor lights that is suspended between two points.” According to 225.6(B), the conductors for festoon lighting must be 12 AWG or larger unless they are supported by a messenger wire. On all spans of festoon lighting exceeding 40 ft, messenger wire is required and it must be supported by strain insulators. Exhibit 225.2 illustrates an installation of festoon lighting that complies with the minimum clearance above grade requirement specified in 225.18(1). The maximum distance between conductor supports is 40 ft unless a messenger wire is installed to support the current-carrying conductors.

**EXHIBIT 225.2** Messenger wire required by 225.6(B) for festoon lighting conductors in a span exceeding 40 ft.

Attachment of festoon lighting to fire escapes, plumbing equipment, or metal drain spouts is prohibited because the attachment could provide a path to ground. Moreover, such methods of attachment could not be relied on for a permanent or secure means of support.

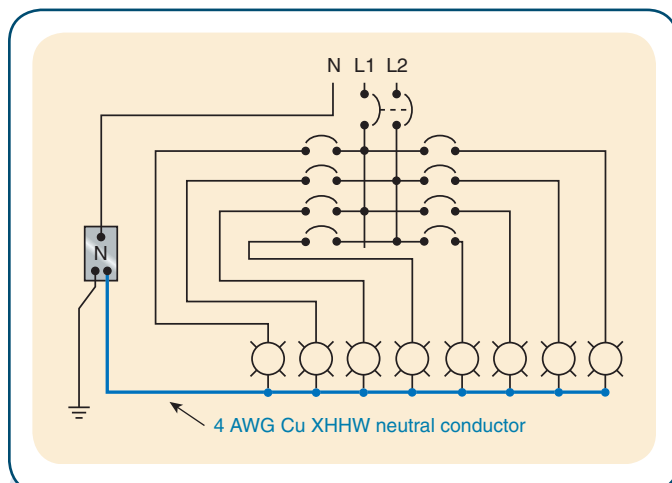

## 225.7 Lighting Equipment Installed Outdoors

**(A) General.** For the supply of lighting equipment installed outdoors, the branch circuits shall comply with Article 210 and 225.7(B) through (D).

**(B) Common Neutral.** The ampacity of the neutral conductor shall not be less than the maximum net calculated load current between the neutral conductor and all ungrounded conductors connected to any one phase of the circuit.

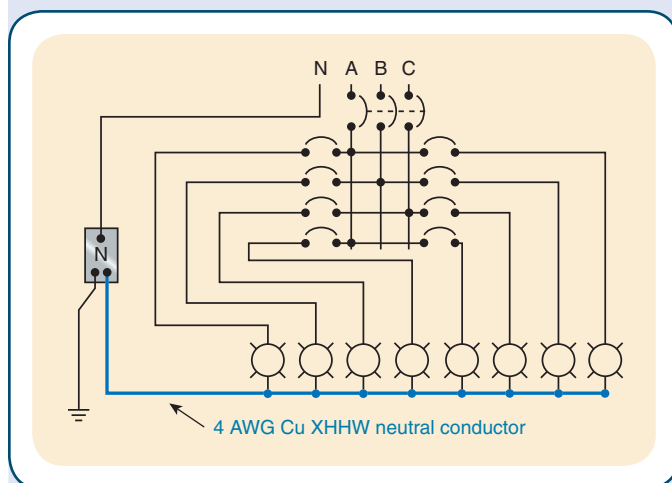

As indicated in 200.4, there are specific provisions in the *Code* that permit the use of a single neutral conductor shared between multiple ungrounded branch-circuit conductors. For outdoor lighting, 225.7(B) permits the use of a common or shared neutral conductor for more than one branch circuit. The branch circuit configuration can be two-wire, line-to-neutral connected — in which multiple ungrounded conductors share a common neutral — or it can be configured in a single- or 3-phase multiwire arrangement. The neutral capacity is required to be not less than the total load of all ungrounded conductors connected to any one phase of the circuit.

Exhibit 225.3 illustrates a 120/240-volt, single-phase, 3-wire system, and Exhibit 225.4 illustrates a 208Y/120-volt, 3-phase, 4-wire system. In Exhibit 225.3, all branch circuits are rated at 20 amperes. The maximum unbalanced current that can occur is four times 20 amperes, or 80 am-

**EXHIBIT 225.3** A 120/240-volt, single-phase, 3-wire system (branch circuits rated at 20 amperes for sizing ungrounded conductors; maximum unbalanced current that can occur is 80 amperes and is used to size the common neutral conductor).

peres. In Exhibit 225.4, all branch circuits also are rated at 20 amperes. The maximum unbalanced current that can occur on a 3-phase system with the load connected as shown is 80 amperes, due to the load on phase A.

**EXHIBIT 225.4** A 208Y/120-volt, 3-phase, 4-wire system (branch circuits rated at 20 amperes for sizing ungrounded conductors; maximum unbalanced current that can occur is 80 amperes and is used to size the common neutral conductor).

**(C) 277 Volts to Ground.** Circuits exceeding 120 volts, nominal, between conductors and not exceeding 277 volts, nominal, to ground shall be permitted to supply luminaires for illumination of outdoor areas of industrial establishments, office buildings, schools, stores, and other commercial or public buildings.

Branch circuits for the outdoor illumination of industrial, commercial, and institutional buildings are permitted to operate at a maximum voltage to ground of 277 volts as specified in 210.6. See 210.6(D) for tunnel and pole-mounted luminaires with voltages greater than 277 volts to ground. The restrictions outlined in 225.7(C) are in addition to those in 210.6(C).

**(D) 600 Volts Between Conductors.** Circuits exceeding 277 volts, nominal, to ground and not exceeding 600 volts, nominal, between conductors shall be permitted to supply the auxiliary equipment of electric-discharge lamps in accordance with 210.6(D)(1).

Section 210.6(D)(1) contains the minimum height requirements for circuits exceeding 277 volts, nominal, to ground but not exceeding 600 volts, nominal, between conductors for circuits that supply the auxiliary equipment of electric-discharge lamps.

## 225.8 Calculation of Loads 600 Volts, Nominal, or Less

**(A) Branch Circuits.** The load on outdoor branch circuits shall be as determined by 220.10.

**(B) Feeders.** The load on outdoor feeders shall be as determined by Part III of Article 220.

## 225.10 Wiring on Buildings

The installation of outside wiring on surfaces of buildings shall be permitted for circuits of not over 600 volts, nominal, as open wiring on insulators, as multiconductor cable, as Type MC cable, as Type UF cable, as Type MI cable, as messenger-supported wiring, in rigid metal conduit, in intermediate metal conduit, in rigid polyvinyl chloride (PVC) conduit, in reinforced thermosetting resin conduit (RTRC), in cable trays, as cablebus, in wireways, in auxiliary gutters, in electrical metallic tubing, in flexible metal conduit, in liquidtight flexible metal conduit, in liquidtight flexible non-metallic conduit, and in busways. Circuits of over 600 volts, nominal, shall be installed as provided in 300.37.

## 225.11 Circuit Exits and Entrances

Where outside branch and feeder circuits leave or enter a building, the requirements of 230.52 and 230.54 shall apply.

Section 225.11 references the requirements in 230.52 and 230.54. In addition, 225.18 covers the requirements for

clearances from ground (not over 600 volts), and 225.19 covers the requirements for clearances from buildings for conductors not over 600 volts. See 225.19(D) for final span clearances from windows, doors, fire escapes, and similar area where overhead conductors are susceptible to contact by persons. Exhibit 225.5 shows an example of where these clearance requirements apply.

**EXHIBIT 225.5** Attachment to buildings, clearances from building openings and other areas where persons could come in contact with overhead conductors, and conductor clearances from grade, driveways, parking lots or roads are covered by the requirements of 225.11, 225.18, and 225.19.

## 225.12 Open-Conductor Supports

Open conductors shall be supported on glass or porcelain knobs, racks, brackets, or strain insulators.

## 225.14 Open-Conductor Spacings

**(A) 600 Volts, Nominal, or Less.** Conductors of 600 volts, nominal, or less, shall comply with the spacings provided in Table 230.51(C).

**(B) Over 600 Volts, Nominal.** Conductors of over 600 volts, nominal, shall comply with the spacings provided in 110.36 and 490.24.

**(C) Separation from Other Circuits.** Open conductors shall be separated from open conductors of other circuits or systems by not less than 100 mm (4 in.).

**(D) Conductors on Poles.** Conductors on poles shall have a separation of not less than 300 mm (1 ft) where not placed on racks or brackets. Conductors supported on poles shall provide a horizontal climbing space not less than the following:

- (1) Power conductors below communications conductors — 750 mm (30 in.)
- (2) Power conductors alone or above communications conductors:
  - a. 300 volts or less — 600 mm (24 in.)
  - b. Over 300 volts — 750 mm (30 in.)
- (3) Communications conductors below power conductors — same as power conductors
- (4) Communications conductors alone — no requirement

Sufficient space is required for personnel to climb over or through conductors to safely work with conductors on the pole.

### 225.15 Supports over Buildings

Supports over a building shall be in accordance with 230.29.

### 225.16 Attachment to Buildings

**(A) Point of Attachment.** The point of attachment to a building shall be in accordance with 230.26.

**(B) Means of Attachment.** The means of attachment to a building shall be in accordance with 230.27.

### 225.17 Masts as Supports

Where a mast is used for the support of final spans of feeders or branch circuits, it shall be of adequate strength or be supported by braces or guys to withstand safely the strain imposed by the overhead drop. Where raceway-type masts are used, all raceway fittings shall be identified for use with masts. Only the feeder or branch-circuit conductors specified within this section shall be permitted to be attached to the feeder and/or branch-circuit mast.

Section 225.17 provides the same rules for masts associated with and supporting overhead branch circuits and feeders as are required for masts associated with and supporting service drops in 230.28. A mast supporting an overhead branch circuit or feeder span is not permitted to support conductors of other systems, such as overhead conductor spans for signaling, communications, or CATV systems.

### 225.18 Clearance for Overhead Conductors and Cables

Overhead spans of open conductors and open multiconductor cables of not over 600 volts, nominal, shall have a clearance of not less than the following:

- (1) 3.0 m (10 ft) — above finished grade, sidewalks, or from any platform or projection from which they might be reached where the voltage does not exceed 150 volts to ground and accessible to pedestrians only
- (2) 3.7 m (12 ft) — over residential property and driveways, and those commercial areas not subject to truck traffic where the voltage does not exceed 300 volts to ground
- (3) 4.5 m (15 ft) — for those areas listed in the 3.7-m (12-ft) classification where the voltage exceeds 300 volts to ground
- (4) 5.5 m (18 ft) — over public streets, alleys, roads, parking areas subject to truck traffic, driveways on other than residential property, and other land traversed by vehicles, such as cultivated, grazing, forest, and orchard
- (5) 7.5 m (24.5 ft) — over track rails of railroads

### 225.19 Clearances from Buildings for Conductors of Not over 600 Volts, Nominal

**(A) Above Roofs.** Overhead spans of open conductors and open multiconductor cables shall have a vertical clearance of not less than 2.5 m (8 ft) above the roof surface. The vertical clearance above the roof level shall be maintained for a distance not less than 900 mm (3 ft) in all directions from the edge of the roof.

*Exception No. 1: The area above a roof surface subject to pedestrian or vehicular traffic shall have a vertical clearance from the roof surface in accordance with the clearance requirements of 225.18.*

*Exception No. 2: Where the voltage between conductors does not exceed 300, and the roof has a slope of 100 mm in 300 mm (4 in. in 12 in.) or greater, a reduction in clearance to 900 mm (3 ft) shall be permitted.*

*Exception No. 3: Where the voltage between conductors does not exceed 300, a reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (1) not more than 1.8 m (6 ft) of the conductors, 1.2 m (4 ft) horizontally, pass above the roof overhang and (2) they are terminated at a through-the-roof raceway or approved support.*

*Exception No. 4: The requirement for maintaining the vertical clearance 900 mm (3 ft) from the edge of the roof shall not apply to the final conductor span where the conductors are attached to the side of a building.*

**(B) From Nonbuilding or Nonbridge Structures.** From signs, chimneys, radio and television antennas, tanks, and other nonbuilding or nonbridge structures, clearances — vertical, diagonal, and horizontal — shall not be less than 900 mm (3 ft).

**(C) Horizontal Clearances.** Clearances shall not be less than 900 mm (3 ft).

**(D) Final Spans.** Final spans of feeders or branch circuits shall comply with 225.19(D)(1), (D)(2), and (D)(3).

**(1) Clearance from Windows.** Final spans to the building they supply, or from which they are fed, shall be permitted to be attached to the building, but they shall be kept not less than 900 mm (3 ft) from windows that are designed to be opened, and from doors, porches, balconies, ladders, stairs, fire escapes, or similar locations.

*Exception: Conductors run above the top level of a window shall be permitted to be less than the 900-mm (3-ft) requirement.*

**(2) Vertical Clearance.** The vertical clearance of final spans above, or within 900 mm (3 ft) measured horizontally of, platforms, projections, or surfaces from which they might be reached shall be maintained in accordance with 225.18.

**(3) Building Openings.** The overhead branch-circuit and feeder conductors shall not be installed beneath openings through which materials may be moved, such as openings in farm and commercial buildings, and shall not be installed where they obstruct entrance to these buildings' openings.

**(E) Zone for Fire Ladders.** Where buildings exceed three stories or 15 m (50 ft) in height, overhead lines shall be arranged, where practicable, so that a clear space (or zone) at least 1.8 m (6 ft) wide will be left either adjacent to the buildings or beginning not over 2.5 m (8 ft) from them to facilitate the raising of ladders when necessary for fire fighting.

## 225.20 Mechanical Protection of Conductors

Mechanical protection of conductors on buildings, structures, or poles shall be as provided for services in 230.50.

## 225.21 Multiconductor Cables on Exterior Surfaces of Buildings

Supports for multiconductor cables on exterior surfaces of buildings shall be as provided in 230.51.

## 225.22 Raceways on Exterior Surfaces of Buildings or Other Structures

Raceways on exteriors of buildings or other structures shall be arranged to drain and shall be **suitable for use** in wet locations.

Section 225.22 requires raceways in exterior locations to be raintight; that is, “constructed or protected so that exposure to a beating rain will not result in the entrance of water under specified test conditions,” as defined in Article 100.

As specified in 342.42(A), 344.42(A), and 348.42, all conduit bodies, fittings, and boxes used in wet locations must be provided with threaded hubs or other approved means, and threadless couplings and connectors used with metal conduit or electrical metallic tubing installed on the exterior of a building must be of the raintight type.

If raceways are exposed to weather or rain through weatherhead openings, condensation is likely to occur, causing moisture to accumulate within raceways at low points of the installation and in junction boxes. Therefore, raceways are required by 225.22 to be installed so as to allow moisture to drain from the raceway through drain holes or other means provided at appropriate locations. The raintight requirement applies only to raceways installed in wet locations.

## 225.24 Outdoor Lampholders

Where outdoor lampholders are attached as pendants, the connections to the circuit wires shall be staggered. Where such lampholders have terminals of a type that puncture the insulation and make contact with the conductors, they shall be attached only to conductors of the stranded type.

Splices to branch-circuit conductors for outdoor lampholders of the Edison-base type or “pigtail” sockets are required by 225.24 to be staggered so that splices will not be in close proximity to each other. Pin-type terminal sockets must be attached to stranded conductors only and are intended for installations for temporary lighting or decorations, signs, or specifically approved applications.

## 225.25 Location of Outdoor Lamps

Locations of lamps for outdoor lighting shall be below all energized conductors, transformers, or other electric utilization equipment, unless either of the following apply:

- (1) Clearances or other safeguards are provided for relamping operations.
- (2) Equipment is controlled by a disconnecting means that can be locked in the open position.

The objective of 225.25 is to protect personnel while relamping outdoor luminaires. However, 225.18 requires a minimum clearance for open conductors of 10 ft above grade or platforms; therefore, in some cases it may be difficult to keep all electrical equipment above the lamps. Section

225.25(1) allows other clearances or safeguards to permit safe relamping, while 225.25(2) provides another alternative for safe relamping through the use of a disconnecting means that can be locked in open or off position. This disconnecting means controls the circuit supplying the equipment that poses a hazard to personnel while they are relamping luminaires.

### 225.26 Vegetation as Support

Vegetation such as trees shall not be used for support of overhead conductor spans.

Overhead conductor spans attached to a tree are subject to damage over the course of time as normal tree growth around the attachment device causes the mounting insulators to break and the conductor insulation to be degraded. The requirement in 225.26 reduces the likelihood of chafing of the conductor insulation and the danger of shock to tree trimmers and tree climbers. However, outdoor luminaires and associated equipment are permitted by 410.36(G) to be supported by trees. To prevent the chafing damage, conductors are run up the tree from an underground wiring method. See 300.5(D) for requirements on the protection of direct-buried conductors emerging from below grade.

### 225.27 Raceway Seal

Where a raceway enters a building or structure from an underground distribution system, it shall be sealed in accordance with 300.5(G). Spare or unused raceways shall also be sealed. Sealants shall be identified for use with the cable insulation, shield, or other components.

## II. Buildings or Other Structures Supplied by a Feeder(s) or Branch Circuit(s)

Part II of Article 225 covers outside branch circuits and feeders on single managed properties where outside branch circuits and feeders are the source of electrical supply for buildings and structures. Important in the application of the Part II requirements are the Article 100 definitions of service point, service, service equipment, feeder, and branch circuit. Determining what constitutes a set of feeder or branch-circuit conductors versus a set of service conductors depends on a clear understanding of where the service point is located and where the service and service equipment for a premises are located. In some cases, particularly with medium- and high-voltage distribution, the service location of a campus or multibuilding facility is a switchyard or substa-

tion. With the location of the service point and service equipment established, the requirements for outside branch circuits and feeders from Part II (and Part III if over 600 volts) can be properly applied.

Included in Part II of Article 225 are the requirements for overhead and underground feeders that supply buildings or structures on college and other institutional campuses, multibuilding industrial facilities, multibuilding commercial facilities, and other facilities where the electrical supply is an outdoor feeder or branch circuit. The feeders and branch circuits covered in Part II of Article 225 may originate in one building or structure and supply another building or structure; or they may originate in outdoor equipment such as freestanding switchboards, switchgear, transformers, or generators and supply equipment located in buildings or structures. Such distribution is permitted under the condition that the entire premises is under a single management. Many of the requirements in Part II covering the number of feeders or branch circuits and the location and type of disconnecting means are similar to the requirements for services in Article 230.

### 225.30 Number of Supplies

A building or other structure that is served by a branch circuit or feeder on the load side of a service disconnecting means shall be supplied by only one feeder or branch circuit unless permitted in 225.30(A) through (E). For the purpose of this section, a multiwire branch circuit shall be considered a single circuit.

Where a branch circuit or feeder originates in these additional buildings or other structures, only one feeder or branch circuit shall be permitted to supply power back to the original building or structure, unless permitted in 225.30(A) through (E).

For the purpose of this section, a multiwire branch circuit shall be considered a single circuit.

**(A) Special Conditions.** Additional feeders or branch circuits shall be permitted to supply the following:

- (1) Fire pumps
- (2) Emergency systems
- (3) Legally required standby systems
- (4) Optional standby systems
- (5) Parallel power production systems
- (6) Systems designed for connection to multiple sources of supply for the purpose of enhanced reliability

The fundamental requirement of 225.30 is that a building or structure be supplied by a single branch circuit or feeder, similar to the rule for a single service in 230.2. Sections

225.30(A) through (E) identify conditions under which a building or structure is permitted to be supplied by multiple sources. To address the need for increased reliability of the power source to a premises where critical operational loads (not classed as emergency or legally required standby) are supplied, 225.30(A)(6) is a condition where multiple feeder or branch-circuit sources are permitted. Double-ended (main-tie-main) switchgear supplied by two feeders is an example of the type of source covered by this provision.

**(B) Special Occupancies.** By special permission, additional feeders or branch circuits shall be permitted for either of the following:

- (1) Multiple-occupancy buildings where there is no space available for supply equipment accessible to all occupants
- (2) A single building or other structure sufficiently large to make two or more supplies necessary

**(C) Capacity Requirements.** Additional feeders or branch circuits shall be permitted where the capacity requirements are in excess of 2000 amperes at a supply voltage of 600 volts or less.

**(D) Different Characteristics.** Additional feeders or branch circuits shall be permitted for different voltages, frequencies, or phases or for different uses, such as control of outside lighting from multiple locations.

**(E) Documented Switching Procedures.** Additional feeders or branch circuits shall be permitted to supply installations under single management where documented safe switching procedures are established and maintained for disconnection.

Buildings on college campuses, multibuilding industrial facilities, and multibuilding commercial facilities are permitted to be supplied by secondary loop supply (secondary selective) networks, provided that documented switching procedures are established. These switching procedures must establish a method to safely operate switches for the facility during maintenance and during alternative supply and emergency supply conditions. Keyed interlock systems are often used to reduce the likelihood of inappropriate switching procedures that could result in hazardous conditions.

### 225.31 Disconnecting Means

Means shall be provided for disconnecting all ungrounded conductors that supply or pass through the building or structure.

### 225.32 Location

The disconnecting means shall be installed either inside or outside of the building or structure served or where the conductors pass through the building or structure. The disconnecting means shall be at a readily accessible location nearest the point of entrance of the conductors. For the purposes of this section, the requirements in 230.6 shall be utilized.

*Exception No. 1: For installations under single management, where documented safe switching procedures are established and maintained for disconnection, and where the installation is monitored by qualified individuals, the disconnecting means shall be permitted to be located elsewhere on the premises.*

*Exception No. 2: For buildings or other structures qualifying under the provisions of Article 685, the disconnecting means shall be permitted to be located elsewhere on the premises.*

*Exception No. 3: For towers or poles used as lighting standards, the disconnecting means shall be permitted to be located elsewhere on the premises.*

*Exception No. 4: For poles or similar structures used only for support of signs installed in accordance with Article 600, the disconnecting means shall be permitted to be located elsewhere on the premises.*

The basic requirement on locating the disconnecting means for a feeder or branch circuit supplying a structure is essentially the same as that specified for services in 230.70(A), but an important difference applies to feeder and branch-circuit sources. Unlike a premises supplied by a service, where a building or structure is supplied by a feeder or branch circuit, there always has to be a feeder or branch-circuit disconnecting means at the building or structure supplied unless one of the conditions in Exception No. 1 through Exception No. 4 to 225.32 can be applied. As is the case with many campus-style facilities supplied by a single utility service, the service disconnecting means may be remote from the buildings or structures supplied. In such installations, the supply conductors to the buildings or structures are feeders or branch circuits, and the main requirement of this section is that the feeder or branch-circuit disconnecting means is to be located inside or outside the building or structure supplied, at the point nearest to where the supply conductors enter the building or structure. This requirement applies to conductors that supply a building and to conductors that pass through a building.

This requirement ensures that, where the service disconnecting means is remote from a building or structure, there is a disconnecting means for the feeder or branch cir-

cuit located at the building or structure to facilitate ready disconnection of the power. Outside disconnecting means are not required to be physically attached to the building or structure supplied, as would be the case with feeder-supplied outside freestanding switchgear located at the building or structure. In addition, this disconnecting means requirement is modified by the rules in 700.12(B)(6), 701.12(B)(5), and 702.12 for emergency, legally required standby, and optional standby feeders supplied by an outdoor generator set.

Exhibit 225.6 is an example of a disconnecting means for a generator feeder that can be used to meet the requirements of both Article 225 and Articles 700, 701, or 702 as applicable. The disconnecting means for the generator feeder can be used to meet the applicable requirements of Article 225, 445, and 700, 701 and/or 702. The disconnecting means is required to be “within sight” of the building or structure supplied by the generator. A conditional exception to 700.12(B)(6) permits the disconnecting means for an outdoor generator supplying an emergency system to be located other than within sight of the building(s) or structure(s) supplied by the generator. This exception contains the same conditions that are used in 225.32, Exception No.1.

**EXHIBIT 225.6** Disconnecting means for alternate source feeder supplying emergency, legally required standby, or optional standby loads or a combination of the three.

### 225.33 Maximum Number of Disconnects

**(A) General.** The disconnecting means for each supply permitted by 225.30 shall consist of not more than six switches or six circuit breakers mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard. There shall be no more than six disconnects per supply grouped in any one location.

*Exception:* For the purposes of this section, disconnecting means used solely for the control circuit of the ground-fault protection system, or the control circuit of the power-operated supply disconnecting means, installed as part of the listed equipment, shall not be considered a supply disconnecting means.

**(B) Single-Pole Units.** Two or three single-pole switches or breakers capable of individual operation shall be permitted on multiwire circuits, one pole for each ungrounded conductor, as one multipole disconnect, provided they are equipped with identified handle ties or a master handle to disconnect all ungrounded conductors with no more than six operations of the hand.

### 225.34 Grouping of Disconnects

**(A) General.** The two to six disconnects as permitted in 225.33 shall be grouped. Each disconnect shall be marked to indicate the load served.

*Exception:* One of the two to six disconnecting means permitted in 225.33, where used only for a water pump also intended to provide fire protection, shall be permitted to be located remote from the other disconnecting means.

**(B) Additional Disconnecting Means.** The one or more additional disconnecting means for fire pumps or for emergency, legally required standby or optional standby system permitted by 225.30 shall be installed sufficiently remote from the one to six disconnecting means for normal supply to minimize the possibility of simultaneous interruption of supply.

### 225.35 Access to Occupants

In a multiple-occupancy building, each occupant shall have access to the occupant's supply disconnecting means.

*Exception:* In a multiple-occupancy building where electric supply and electrical maintenance are provided by the building management and where these are under continuous building management supervision, the supply disconnecting means supplying more than one occupancy shall be permitted to be accessible to authorized management personnel only.

### 225.36 Suitable for Service Equipment

The disconnecting means specified in 225.31 shall be suitable for use as service equipment.

*Exception:* For garages and outbuildings on residential property, a snap switch or a set of 3-way or 4-way snap switches shall be permitted as the disconnecting means.

### 225.37 Identification

Where a building or structure has any combination of feeders, branch circuits, or services passing through it or supplying it, a permanent plaque or directory shall be installed at each feeder and branch-circuit disconnect location denoting all other services, feeders, or branch circuits supplying that building or structure or passing through that building or structure and the area served by each.

The requirement of 225.37 correlates with 230.2(E) in that where a building has multiple sources of supply, permanent identification at each supply (service, feeder, and branch circuit) disconnecting means is required. The term *permanent* indicates that this required identification has to have the same permanency as the disconnecting means itself. This identification is an important safety feature in an emergency condition, because in many cases first responders are not familiar with the electrical distribution system of a facility. In addition to 225.37 and 230.2(E), identification of power sources is covered by the requirements of 700.7(A) for emergency sources, 701.7(A) for legally required standby sources, 702.7(A) for optional standby sources, and 705.10 for parallel power production sources.

*Exception No. 1: A plaque or directory shall not be required for large-capacity multibuilding industrial installations under single management, where it is ensured that disconnection can be accomplished by establishing and maintaining safe switching procedures.*

*Exception No. 2: This identification shall not be required for branch circuits installed from a dwelling unit to a second building or structure.*

### 225.38 Disconnect Construction

Disconnecting means shall meet the requirements of 225.38(A) through (D).

*Exception: For garages and outbuildings on residential property, snap switches or 3-way or 4-way snap switches shall be permitted as the disconnecting means.*

**(A) Manually or Power Operable.** The disconnecting means shall consist of either (1) a manually operable switch or a circuit breaker equipped with a handle or other suitable operating means or (2) a power-operable switch or circuit breaker, provided the switch or circuit breaker can be opened by hand in the event of a power failure.

**(B) Simultaneous Opening of Poles.** Each building or structure disconnecting means shall simultaneously disconnect all ungrounded supply conductors that it controls from the building or structure wiring system.

**(C) Disconnection of Grounded Conductor.** Where the building or structure disconnecting means does not disconnect the grounded conductor from the grounded conductors in the building or structure wiring, other means shall be provided for this purpose at the location of disconnecting means. A terminal or bus to which all grounded conductors can be attached by means of pressure connectors shall be permitted for this purpose.

In a multisection switchboard, disconnects for the grounded conductor shall be permitted to be in any section of the switchboard, provided any such switchboard section is marked.

**(D) Indicating.** The building or structure disconnecting means shall plainly indicate whether it is in the open or closed position.

### 225.39 Rating of Disconnect

The feeder or branch-circuit disconnecting means shall have a rating of not less than the calculated load to be supplied, determined in accordance with Parts I and II of Article 220 for branch circuits, Part III or IV of Article 220 for feeders, or Part V of Article 220 for farm loads. Where the branch circuit or feeder disconnecting means consists of more than one switch or circuit breaker, as permitted by 225.33, combining the ratings of all the switches or circuit breakers for determining the rating of the disconnecting means shall be permitted. In no case shall the rating be lower than specified in 225.39(A), (B), (C), or (D).

**(A) One-Circuit Installation.** For installations to supply only limited loads of a single branch circuit, the branch circuit disconnecting means shall have a rating of not less than 15 amperes.

**(B) Two-Circuit Installations.** For installations consisting of not more than two 2-wire branch circuits, the feeder or branch-circuit disconnecting means shall have a rating of not less than 30 amperes.

**(C) One-Family Dwelling.** For a one-family dwelling, the feeder disconnecting means shall have a rating of not less than 100 amperes, 3-wire.

**(D) All Others.** For all other installations, the feeder or branch-circuit disconnecting means shall have a rating of not less than 60 amperes.

### 225.40 Access to Overcurrent Protective Devices

Where a feeder overcurrent device is not readily accessible, branch-circuit overcurrent devices shall be installed on the load side, shall be mounted in a readily accessible location,

and shall be of a lower ampere rating than the feeder over-current device.

### III. Over 600 Volts

#### 225.50 Sizing of Conductors

The sizing of conductors over 600 volts shall be in accordance with 210.19(B) for branch circuits and 215.2(B) for feeders.

#### 225.51 Isolating Switches

Where oil switches or air, oil, vacuum, or sulfur hexafluoride circuit breakers constitute a building disconnecting means, an isolating switch with visible break contacts and meeting the requirements of 230.204(B), (C), and (D) shall be installed on the supply side of the disconnecting means and all associated equipment.

*Exception: The isolating switch shall not be required where the disconnecting means is mounted on removable truck panels or metal-enclosed switchgear units that cannot be opened unless the circuit is disconnected and that, when removed from the normal operating position, automatically disconnect the circuit breaker or switch from all energized parts.*

#### 225.52 Disconnecting Means

**(A) Location.** A building or structure disconnecting means shall be located in accordance with 225.32, or it shall be electrically operated by a similarly located remote-control device.

**(B) Type.** Each building or structure disconnect shall simultaneously disconnect all ungrounded supply conductors it controls and shall have a fault-closing rating not less than the maximum available short-circuit current available at its supply terminals.

*Exception: Where the individual disconnecting means consists of fused cutouts, the simultaneous disconnection of all ungrounded supply conductors shall not be required if there is a means to disconnect the load before opening the cutouts. A permanent legible sign shall be installed adjacent to the fused cutouts indicating the above requirement.*

Where fused switches or separately mounted fuses are installed, the fuse characteristics shall be permitted to contribute to the fault closing rating of the disconnecting means.

The requirement for a disconnecting means for over-600-volt feeders to buildings or structures is similar to the requirements found in 230.205(B). This disconnect can be an air, oil, SF<sub>6</sub>, or vacuum breaker. It also can be an air, oil, SF<sub>6</sub>,

or vacuum switch. Where a switch is used, fuses are permitted to help with the fault-closing capability of the switch. The common practices of using fused load-break cutouts to switch sections of overhead lines and using load-break elbows to switch sections of underground lines are permitted. However, the building disconnecting means must be gang-operated to simultaneously open and close all ungrounded supply conductors. Load-break elbows and fused cutouts cannot be used as the building disconnection means.

**(C) Locking.** Disconnecting means shall be capable of being locked in the open position. The provisions for locking shall remain in place with or without the lock installed.

*Exception: Where an individual disconnecting means consists of fused cutouts, a suitable enclosure capable of being locked and sized to contain all cutout fuse holders shall be installed at a convenient location to the fused cutouts.*

**(D) Indicating.** Disconnecting means shall clearly indicate whether they are in the open “off” or closed “on” position.

**(E) Uniform Position.** Where disconnecting means handles are operated vertically, the “up” position of the handle shall be the “on” position.

*Exception: A switching device having more than one “on” position, such as a double throw switch, shall not be required to comply with this requirement.*

**(F) Identification.** Where a building or structure has any combination of feeders, branch circuits, or services passing through or supplying it, a permanent plaque or directory shall be installed at each feeder and branch-circuit disconnect location that denotes all other services, feeders, or branch circuits supplying that building or structure or passing through that building or structure and the area served by each.

#### 225.56 Inspections and Tests

**(A) Pre-Energization and Operating Tests.** The complete electrical system shall be performance tested when first installed on-site. Each protective, switching, and control circuit shall be adjusted in accordance with the recommendations of the protective device study and tested by actual operation using current injection or equivalent methods as necessary to ensure that each and every such circuit operates correctly to the satisfaction of the authority having jurisdiction.

To ensure proper operation of protective and switching devices and of control circuits, outdoor feeder and branch

circuit installations rated over 600 volts are required to be performance tested prior to being energized. The authority having jurisdiction must concur that the tests demonstrate proper operation. Section 225.56(B) requires that a report of all tests performed in accordance with 225.56(A) be provided to the authority having jurisdiction prior to energizing the system.

- (1) Instrument Transformers.** All instrument transformers shall be tested to verify correct polarity and burden.
- (2) Protective Relays.** Each protective relay shall be demonstrated to operate by injecting current or voltage, or both, at the associated instrument transformer output terminal and observing that the associated switching and signaling functions occur correctly and in proper time and sequence to accomplish the protective function intended.
- (3) Switching Circuits.** Each switching circuit shall be observed to operate the associated equipment being switched.
- (4) Control and Signal Circuits.** Each control or signal circuit shall be observed to perform its proper control function or produce a correct signal output.
- (5) Metering Circuits.** All metering circuits shall be verified to operate correctly from voltage and current sources, similarly to protective relay circuits.
- (6) Acceptance Tests.** Complete acceptance tests shall be performed, after the station installation is completed, on all assemblies, equipment, conductors, and control and protective systems, as applicable, to verify the integrity of all the systems.
- (7) Relays and Metering Utilizing Phase Differences.** All relays and metering that use phase differences for operation shall be verified by measuring phase angles at the relay under actual load conditions after operation commences.
- (B) Test Report.** A test report covering the results of the tests required in 225.56(A) shall be delivered to the authority having jurisdiction prior to energization.

Informational Note: For acceptance specifications, see NETA ATS-2007, *Acceptance Testing Specifications for Electrical Power Distribution Equipment and Systems*, published by the InterNational Electrical Testing Association.

**225.60 Clearances over Roadways, Walkways, Rail, Water, and Open Land**

**(A) 22 kV, Nominal, to Ground or Less.** The clearances over roadways, walkways, rail, water, and open land for con-

ductors and live parts up to 22 kV, nominal, to ground or less shall be not less than the values shown in Table 225.60.

**TABLE 225.60 Clearances over Roadways, Walkways, Rail, Water, and Open Land**

Location	Clearance	
	m	ft
Open land subject to vehicles, cultivation, or grazing	5.6	18.5
Roadways, driveways, parking lots, and alleys	5.6	18.5
Walkways	4.1	13.5
Rails	8.1	26.5
Spaces and ways for pedestrians and restricted traffic	4.4	14.5
Water areas not suitable for boating	5.2	17.0

**(B) Over 22 kV Nominal to Ground.** Clearances for the categories shown in Table 225.60 shall be increased by 10 mm (0.4 in.) per kV above 22,000 volts.

**(C) Special Cases.** For special cases, such as where crossings will be made over lakes, rivers, or areas using large vehicles such as mining operations, specific designs shall be engineered considering the special circumstances and shall be approved by the authority having jurisdiction.

Informational Note: For additional information, see ANSI C2-2007, *National Electrical Safety Code*.

Section 225.60 and its associated table provide clearance requirements and specific distances that correlate with requirements in the *National Electrical Safety Code*® (NESC).

**225.61 Clearances over Buildings and Other Structures**

**(A) 22 kV Nominal to Ground or Less.** The clearances over buildings and other structures for conductors and live parts up to 22 kV, nominal, to ground or less shall be not less than the values shown in Table 225.61.

**(B) Over 22 kV Nominal to Ground.** Clearances for the categories shown in Table 225.61 shall be increased by 10 mm (0.4 in.) per kV above 22,000 volts.

Informational Note: For additional information, see ANSI C2-2007, *National Electrical Safety Code*.

**TABLE 225.61 Clearances over Buildings and Other Structures**

Clearance from Conductors or Live Parts from:	Horizontal		Vertical	
	m	ft	m	ft
Building walls, projections, and windows	2.3	7.5	—	—
Balconies, catwalks, and similar areas accessible to people	2.3	7.5	4.1	13.5
Over or under roofs or projections not readily accessible to people	—	—	3.8	12.5
Over roofs accessible to vehicles but not trucks	—	—	4.1	13.5
Over roofs accessible to trucks	—	—	5.6	18.5
Other structures	2.3	7.5	—	—

Section 225.61 and its associated table provide clearance requirements and specific distances over buildings and structures that correlate with requirements in the *National Electrical Safety Code (NESC)*.

## 225.70 Substations

The term *substation* is defined in 225.2 and is used only in Part III of Article 225 covering installations over 600 volts, nominal. The requirements of 225.70 apply to substations located indoors and outdoors. Several other articles contain requirements applicable to substations operating over 600 volts, nominal, including Article 240, Part IX; Article 250, Part X; Article 310, Parts I and II; Article 450, Parts I, II, and III; and Article 490.

### (A) Warning Signs.

**(1) General.** A permanent, legible warning notice carrying the wording “DANGER — HIGH VOLTAGE” shall be placed in a conspicuous position in the following areas:

- (a) At all entrances to electrical equipment vaults and electrical equipment rooms, areas, or enclosures
- (b) At points of access to conductors on all high-voltage conduit systems and cable systems
- (c) On all cable trays containing high-voltage conductors with the maximum spacing of warning notices not to exceed 3 m (10 ft.)

**(2) Isolating Equipment.** Permanent legible signs shall be installed at isolating equipment warning against operation while carrying current, unless the equipment is interlocked so that it cannot be operated under load.

**(3) Fuse Locations.** Suitable warning signs shall be erected in a conspicuous place adjacent to fuses, warning operators not to replace fuses while the circuit is energized.

**(4) Backfeed.** The following steps shall be taken where the possibility of backfeed exists:

(a) Each group-operated isolating switch or disconnecting means shall bear a warning notice to the effect that contacts on either side of the device might be energized.

(b) A permanent, legible, single-line diagram of the station switching arrangement, clearly identifying each point of connection to the high-voltage section, shall be provided in a conspicuous location within sight of each point of connection.

**(5) Metal-Enclosed and Metal-Clad Switchgear.** Where metal-enclosed switchgear is installed, the following steps shall be taken:

(a) A permanent, legible, single-line diagram of the switchgear shall be provided in a readily visible location within sight of the switchgear, and this diagram shall clearly identify interlocks, isolation means, and all possible sources of voltage to the installation under normal or emergency conditions, including all equipment contained in each cubicle, and the marking on the switchgear shall cross-reference the diagram.

*Exception to (a): Where the equipment consists solely of a single cubicle or metal-enclosed unit substation containing only one set of high-voltage switching devices, diagrams shall not be required.*

(b) Permanent, legible signs shall be installed on panels or doors that provide access to live parts over 600 volts and shall carry the wording “DANGER — HIGH VOLTAGE” to warn of the danger of opening while energized.

(c) Where the panel provides access to parts that can only be de-energized and visibly isolated by the serving utility, the warning shall include that access is limited to the serving utility or following an authorization of the serving utility.

### 230.1 Scope

This article covers service conductors and equipment for control and protection of services and their installation requirements.

Informational Note: See Figure 230.1.

**FIGURE 230.1** Services.

The requirements for the subjects covered in Parts I through VIII of Article 230 are arranged as follows:

Subject	Part	Section
General	I	230.2–230.10
Overhead Service Conductors	II	230.22–230.29
Underground Service Conductors	III	230.30–230.33
Service-Entrance Conductors	IV	230.40–230.56
Service-Equipment — General	V	230.62–230.66
Service-Equipment — Disconnecting Means	VI	230.70–230.82
Service-Equipment — Overcurrent Protection	VII	230.90–230.95
Services Exceeding 600 Volts, Nominal	VIII	230.200–230.212

## I. General

### 230.2 Number of Services

A building or other structure served shall be supplied by only one service unless permitted in 230.2(A) through (D). For the purpose of 230.40, Exception No. 2 only, underground sets of conductors, 1/0 AWG and larger, running to the same location and connected together at their supply end but not connected together at their load end shall be considered to be supplying one service.

The general requirement of 230.2 is that a building or other structure be supplied by only one service. However, there are conditions under which a single service may not be adequate to supply a building or structure. Therefore 230.2 permits the installation of additional services, as specified in conditions covered by 230.2(A) through (D). Where more than one service (or combination of service, feeder, and branch circuit) is installed, 230.2(E) requires that a permanent plaque or directory with the pertinent information on the multiple sources of supply be located at each supply source disconnecting means. This information is very important to first responders or other persons who need to disconnect the building or structure from the utility supply.

**(A) Special Conditions.** Additional services shall be permitted to supply the following:

- (1) Fire pumps
- (2) Emergency systems
- (3) Legally required standby systems
- (4) Optional standby systems
- (5) Parallel power production systems

Allowing for completely separate services to the systems and equipment covered in 230.2(A) increases the overall reliability of the power supply to those systems by negating the impact resulting from a disruption of the main building service. It is understood that unless the separate service is supplied from a different utility circuit, the additional service is not protection against an overall system outage, but the effect of an outage resulting from a problem between the service point and the “normal” or main building service equipment is generally limited to the “normal” service and continuity of power to the portion of the electrical system supplied by the additional service is maintained.

- (6) Systems designed for connection to multiple sources of supply for the purpose of enhanced reliability

**(B) Special Occupancies.** By special permission, additional services shall be permitted for either of the following:

- (1) Multiple-occupancy buildings where there is no available space for service equipment accessible to all occupants
- (2) A single building or other structure sufficiently large to make two or more services necessary

Section 230.2(B) permits additional services for certain occupancies by special permission (written consent of the authority having jurisdiction; see the definition of *authority having jurisdiction* in Article 100). The expansion of buildings, shopping centers, and industrial plants often necessitates the addition of one or more services. It may, for example, be impractical or impossible to install one service for an industrial plant with sufficient capacity for any and all future loads. It is also impractical to run extremely long feeders. In order to apply either of the provisions in 230.2(B), written consent from the authority having jurisdiction is needed. Therefore it is advisable to consult early on with the AHJ to ascertain whether the *special permission* required by 230.2(B) can be obtained.

**(C) Capacity Requirements.** Additional services shall be permitted under any of the following:

- (1) Where the capacity requirements are in excess of 2000 amperes at a supply voltage of 600 volts or less
- (2) Where the load requirements of a single-phase installation are greater than the serving agency normally supplies through one service
- (3) By special permission

Where two or more services are needed, 230.2(C) does not require that each service be rated 2000 amperes or that there be one service rated 2000 amperes and the additional service(s) be rated for the calculated load in excess of 2000 amperes. For example, this provision permits a building with a calculated load of 2300 amperes to have two 1200-ampere services. Additional services for lesser loads are also allowed by special permission.

Many electric power companies have specifications for and have adopted special regulations covering certain types of electrical loads and service equipment that may be energized from their lines. Before electrical services for large buildings and facilities are designed, the serving utility should be consulted to determine line and transformer capacities.

**(D) Different Characteristics.** Additional services shall be permitted for different voltages, frequencies, or phases, or for different uses, such as for different rate schedules.

Section 230.2(D) permits the installation of more than one service for different characteristics, such as different volt-

ages, frequencies, single-phase or 3-phase services, or different utility rate schedules. For example, different service characteristics exist between a 3-wire, 120/240-volt, single-phase service and a 3-phase, 4-wire, 480Y/277-volt service. For different applications, such as different rate schedules, this provision allows a second service for supplying a second meter on a different rate. Curtailable loads, interruptible loads, electric heating, and electric water heating are examples of loads that may be on a different rate.

**(E) Identification.** Where a building or structure is supplied by more than one service, or any combination of branch circuits, feeders, and services, a permanent plaque or directory shall be installed at each service disconnect location denoting all other services, feeders, and branch circuits supplying that building or structure and the area served by each. See 225.37.

Section 230.2(E) requires that a permanent plaque or directory be installed at each service disconnecting means location to indicate where the other disconnects that feed the building are located, as illustrated in Exhibit 230.1. All the other services on or in the building or structure and the area served by each must be noted on the plaques or directories. The plaques or directories must be of sufficient durability to withstand the environment in which the service disconnecting means is installed. The term “permanent” implies that the plaque has to be able to convey its information for as long as the service at which it has been installed is operational. See the commentary following 225.37 for further in-

**EXHIBIT 230.1** An example of two separate services installed at one building with permanent plaques or directories at each service disconnecting means location containing information describing all other services and the area served by each.

formation on identification of multiple supply sources to a building or structure.

Exhibits 230.2 through 230.13 illustrate examples of permitted service configurations in accordance with 230.2(B) and (C); 230.40, Exceptions No. 1 and No. 2; 230.71; and 230.72. The exhibits depict a number of service arrangements where more than a single service is, or where multiple sets of service-entrance conductors are, used to supply buildings with one or more than one occupancy.

One building with more than one occupancy

**EXHIBIT 230.2** Two services per 230.2(B)(1) and 230.71(A). Two service drops or two sets of overhead service conductors supplying two services installed at separate locations for a building where there is no available space for service equipment accessible to all occupants. Maximum of six service disconnecting means permitted for each service.

A single-occupancy building with more than one service

**EXHIBIT 230.3** Two services per 230.2(C)(1) and 230.71(A). Two service drops or two sets of overhead service conductors supplying two services installed at separate locations for a building with capacity requirements exceeding 2000 amperes. Maximum of six service disconnecting means permitted for each service.

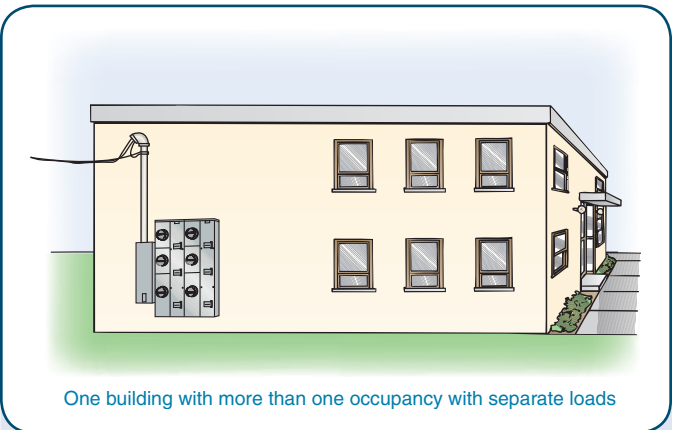

**EXHIBIT 230.4** One service per 230.40, Exception No. 1 and 230.71(A). One service drop or one set of overhead service conductors supplying two service equipment enclosures installed at separate locations, each is permitted to have a maximum of six service disconnecting means.

**EXHIBIT 230.5** One service per 230.40, Exception No. 2 and 230.71(A). One set of overhead service conductors supplying maximum of six separate service disconnecting means enclosures grouped at one location.

There are, of course, other service arrangements not depicted in these illustrations that are acceptable under the provisions of 230.2(A) through (D). Additionally, buildings supplied by a service and also by a feeder as commonly occurs where the building is supplied with emergency, legally required standby and/or optional standby power are subject to the requirements of this article as well as Article 225, 700, 701, and 702 as applicable. The phrase *one location*, as applied to the grouping of service disconnecting means in 230.71(A), is determined by the authority having jurisdiction.

**EXHIBIT 230.6** One service per 230.2 and 230.71(A). One service drop or one set of overhead service conductors supplying a single service equipment enclosure with maximum of six service disconnecting means grouped at one location. Optional arrangement to that shown in Exhibit 230.5.

**EXHIBIT 230.7** One service per 230.2, 230.40, Exception No. 2 and 230.71(A). One service lateral or one set of underground service conductors consisting of six sets of conductors 1/0 AWG or larger, terminating in six separate service equipment enclosures for a maximum of six service disconnecting means grouped in that one location.

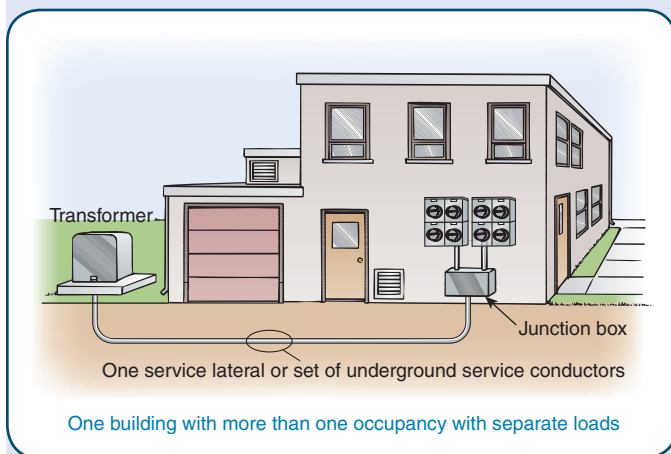

### 230.3 One Building or Other Structure Not to Be Supplied Through Another

Service conductors supplying a building or other structure shall not pass through the interior of another building or other structure.

Although Section 230.3 prohibits service conductors supplying a building or structure from being run through the

**EXHIBIT 230.8** Two services per 230.2(B)(1) and 230.71(A). Two service laterals or two sets of underground service conductors, terminating in two service equipment enclosures installed at separate locations, with each enclosure permitted to have a maximum of six service disconnecting means.

**EXHIBIT 230.9** One service per 230.40, Exception No. 1 and 230.71(A). One service lateral or set of underground service conductors supplying two sets of service-entrance conductors terminating in two service equipment enclosures grouped in one location. The combined number of service disconnecting means in the two enclosures cannot exceed six.

interior of another building or structure, service conductors are permitted to be installed along the exterior of one building to supply another building. Each building served in this manner is required to be provided with a disconnecting means for all ungrounded conductors, in accordance with Part VI, Service Equipment — Disconnecting Means.

For example, in Exhibit 230.14, the service disconnecting means shown for Building No. 1 and Building No. 2 are located on the exterior walls. A disconnecting means suitable for use as service equipment is provided for each building. The requirement to not pass through one building en

**EXHIBIT 230.10** One service per 230.2, 230.40, Exception No. 2 and 230.71(A). Two service laterals or two sets of underground service conductors, each consisting of conductors 1/0 AWG or larger, supplying two sets of service-entrance conductors terminating in two service equipment enclosures grouped in one location. The combined number of service disconnecting means in the two enclosures cannot exceed six.

**EXHIBIT 230.11** Four services per 230.2 and Article 100 definition of building. Four service laterals or four sets of underground service conductors supplying four service equipment enclosures installed at separate locations on a contiguous structure, each enclosure is permitted to have a maximum of six service disconnecting means. Note presence of firewalls. See definition of building in Article 100.

route to another applies only to service conductors and does not prohibit feeders or branch-circuit conductors from running through the interior of a building, exiting that building, and continuing on to supply a separate building or structure. A significant difference between service conductors and feeder and branch-circuit conductors is that the feeders and branch circuits are generally provided with overcurrent protection at the point they receive their supply unless otherwise permitted by 240.21.

**EXHIBIT 230.12** Two services per 230.40, Exception No. 1 and 230.71(A). Two service laterals or two sets of underground service conductors supplying two service equipment enclosures installed at separate locations, each enclosure is permitted to have a maximum of six service disconnecting means.

**EXHIBIT 230.13** One service per 230.40, Exception No. 1 and 230.71(A). One service lateral or one set of underground service conductors supplying four service equipment enclosures installed at different locations, with each enclosure permitted to have a maximum of six service disconnecting means.

## 230.6 Conductors Considered Outside the Building

Conductors shall be considered outside of a building or other structure under any of the following conditions:

- (1) Where installed under not less than 50 mm (2 in.) of concrete beneath a building or other structure

**EXHIBIT 230.14** Service conductors installed in accordance with 230.3 so as not to pass through the interior of Building No. 1 to supply Building No. 2.

- (2) Where installed within a building or other structure in a raceway that is encased in concrete or brick not less than 50 mm (2 in.) thick

Sections 230.6(1) and (2) define two of the conditions that permit service conductors to be considered “outside” a building, as illustrated in Exhibit 230.15.

Service conductors installed in a vault complying with the construction requirements of 450.41 through 450.48 are considered to be outside of a building. For example, this provision is applicable to service conductors originating in a transformer vault located within the interior of a building.

**EXHIBIT 230.15** Service conductors considered outside a building where installed under not less than 2 in. of concrete beneath the building or in a raceway encased by not less than 2 in. of concrete or brick within the building.

The vault does not have to contain a transformer but does have to meet the vault construction requirements contained in Part III of Article 450. Once the conductors leave the vault, the service disconnecting means has to be installed as required by 230.70(A)(1). Service conductors installed under 18 in. of earth beneath the building are also considered outside the building according to 230.6(4). An example of this provision is a building or structure built on piers with service conductors buried beneath and running to a readily accessible service disconnecting means located within the interior of the building or structure. Service conductors passing through a roof overhang as covered in 230.24(A) Exception No. 3 and depicted in Exhibit 230.19 are considered to be *outside the building* per 230.6(5).

- (3) Where installed in any vault that meets the construction requirements of Article 450, Part III
- (4) Where installed in conduit and under not less than 450 mm (18 in.) of earth beneath a building or other structure
- (5) Where installed in overhead service masts on the outside surface of the building traveling through the eave of that building to meet the requirements of 230.24

### 230.7 Other Conductors in Raceway or Cable

Conductors other than service conductors shall not be installed in the same service raceway or service cable.

All feeder and branch-circuit conductors must be separated from service conductors. Service conductors are not provided with overcurrent protection where they receive their supply; they are protected against overload conditions at their load end by the service disconnect fuses or circuit breakers. The amount of current that could be imposed on feeder or branch-circuit conductors, should they be in the same raceway and a fault occur, would be much higher than the ampacity of the feeder or branch-circuit conductors. The gutter space of a panelboard cabinet or other electrical equipment enclosure is not a raceway (see definition of *raceway* in Article 100), therefore is not subject to the requirement of 230.7. Service conductors, feeder conductors, and branch circuit conductors can share the same gutter space, as shown in Exhibit 230.16. Conductor bending space requirements for cabinets are covered in 312.6 and 408.55, and conductor fill requirements for cabinet gutter spaces are covered in 312.8.

*Exception No. 1: Grounding conductors and bonding jumpers.*

*Exception No. 2: Load management control conductors having overcurrent protection.*

**EXHIBIT 230.16** A panelboard cabinet gutter space accommodating a set of service conductors terminating on the 200 ampere main breaker, a set of feeder conductors supplying the adjacent panelboard, and several sets of branch-circuit conductors entering the bottom of the cabinet that will connect to overcurrent protective devices installed on the panelboard. (Courtesy of the International Association of Electrical Inspectors)

Load management control conductors, control circuits, and switch leg conductors for use with special rate meters are permitted to be installed in the service raceway or cable because they are usually short and are directly associated with control or operation of the service conductors. See Exhibit 230.24 for an example.

### 230.8 Raceway Seal

Where a service raceway enters a building or structure from an underground distribution system, it shall be sealed in accordance with 300.5(G). Spare or unused raceways shall also be sealed. Sealants shall be identified for use with the cable insulation, shield, or other components.

Sealant, such as duct seal or a bushing incorporating the physical characteristics of a seal, is required by 230.8 to be used to seal the ends of service raceways. The intent is to prevent water, usually the result of condensation due to temperature differences, from entering the service equipment via the raceway. The sealant material should be compatible with the conductor insulation and should not cause deterioration of the insulation over time. For underground services over 600 volts, nominal, refer to 300.50(F) for raceway seal requirements. See Exhibit 300.10 for an example.

### 230.9 Clearances on Buildings

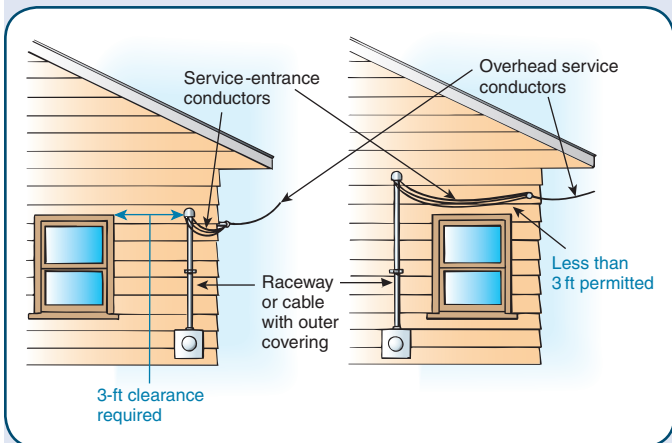

Service conductors and final spans shall comply with 230.9(A), (B), and (C).

**(A) Clearances.** Service conductors installed as open conductors or multiconductor cable without an overall outer jacket shall have a clearance of not less than 900 mm (3 ft) from windows that are designed to be opened, doors, porches, balconies, ladders, stairs, fire escapes, or similar locations.

*Exception: Conductors run above the top level of a window shall be permitted to be less than the 900-mm (3-ft) requirement.*

The 3-ft clearance required by 230.9(A) applies to open conductors, not to a raceway or to a cable assembly that has an overall outer jacket such as Types SE, MC, and MI cables. The intent is to protect the conductors from physical damage and to protect persons from accidental contact with the conductors. The exception permits service conductors, including service-entrance conductors, overhead service conductors, and service-drop conductors, to be located just above window openings, because they are considered out of reach, as illustrated in Exhibit 230.17.

**EXHIBIT 230.17** Required dimensions for service conductors located alongside a window (left) and overhead service conductors above the top level of a window designed to be opened (right).

**(B) Vertical Clearance.** The vertical clearance of final spans above, or within 900 mm (3 ft) measured horizontally of, platforms, projections, or surfaces from which they might be reached shall be maintained in accordance with 230.24(B).

Where service conductors are located within 3 ft horizontally of a balcony or other or similar platform from which a person could reach and touch them, 230.9(B) requires the

conductors to have a clearance of not less than that specified in 230.24(B). The amount of vertical clearance required is a function of the voltage of the overhead conductors.

Exhibit 230.18 illustrates an installation where the 10-ft clearance is based on the voltage and conductor conditions described in 240.24(B)(1).

**EXHIBIT 230.18** Required dimensions for service conductors located above a stair landing, according to 230.9(B) and 230.24(B).

**(C) Building Openings.** Overhead service conductors shall not be installed beneath openings through which materials may be moved, such as openings in farm and commercial buildings, and shall not be installed where they obstruct entrance to these building openings.

Elevated openings in buildings through which materials may be moved, such as barns and storage buildings, are often high enough for the service conductors to be installed below the opening. However, 230.9(C) prohibits such placement in order to reduce the likelihood of damage to the service conductors and the potential for electric shock to persons using the openings.

## 230.10 Vegetation as Support

Vegetation such as trees shall not be used for support of overhead service conductors.

## II. Overhead Service Conductors

### 230.22 Insulation or Covering

Individual conductors shall be insulated or covered.

*Exception: The grounded conductor of a multiconductor cable shall be permitted to be bare.*

By the nature of where they are installed, overhead service conductors are exposed to the environment. Section 110.11 requires conductors to be suitable for the environmental conditions to which they will be exposed including the effects of rain, and other deleterious environmental conditions. Article 310 also addresses environmental conditions including exposure of conductor insulation to sunlight. The grounded conductor (neutral) of triplex or quadraplex overhead service conductors is often bare and used to mechanically support the ungrounded conductors.

### 230.23 Size and Rating

**(A) General.** Conductors shall have sufficient ampacity to carry the current for the load as calculated in accordance with Article 220 and shall have adequate mechanical strength.

When a load is added to any service, the installer must be aware of all existing loads. The potential for overloading the service conductors must be governed by installer responsibility and inspector awareness; they should not rely solely on the usual method of overcurrent protection. The serving electric utility should be notified whenever load is added, to ensure that adequate power is available.

**(B) Minimum Size.** The conductors shall not be smaller than 8 AWG copper or 6 AWG aluminum or copper-clad aluminum.

*Exception: Conductors supplying only limited loads of a single branch circuit — such as small polyphase power, controlled water heaters, and similar loads — shall not be smaller than 12 AWG hard-drawn copper or equivalent.*

**(C) Grounded Conductors.** The grounded conductor shall not be less than the minimum size as required by 250.24(C).

### 230.24 Clearances

Overhead service conductors shall not be readily accessible and shall comply with 230.24(A) through (E) for services not over 600 volts, nominal.

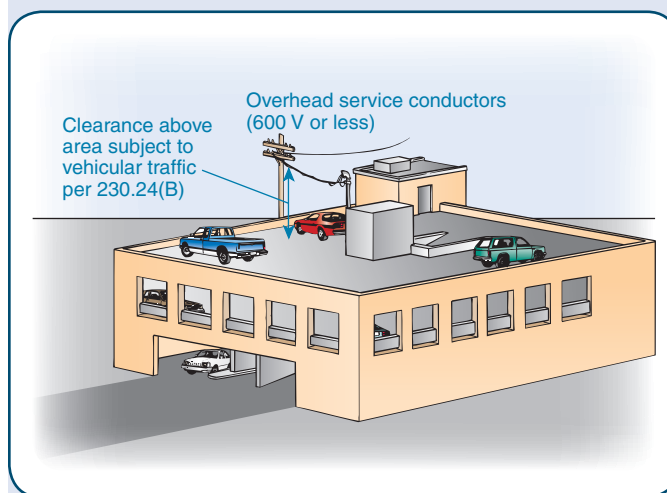

To minimize the potential for making inadvertent contact, overhead service conductors are not permitted to be readily accessible. This main rule applies to services rated 600 volts and less, grounded or ungrounded.

**(A) Above Roofs.** Conductors shall have a vertical clearance of not less than 2.5 m (8 ft) above the roof surface. The vertical clearance above the roof level shall be maintained for a distance of not less than 900 mm (3 ft) in all directions from the edge of the roof.

The general requirement in 230.24(A) is for an 8-ft vertical clearance over the roof surface, extending 3 ft in all directions from the edge. Exception No. 4 to 230.24(A), however, allows the final span of the overhead service conductors to enter this space in order to attach to the building or service mast.

*Exception No. 1: The area above a roof surface subject to pedestrian or vehicular traffic shall have a vertical clearance from the roof surface in accordance with the clearance requirements of 230.24(B).*

Exception No. 1 to 230.24(A) requires overhead service conductors installed above a roof surface subject to vehicular or pedestrian traffic, such as the rooftop parking area shown in Exhibit 230.19, to meet the clearance requirements of 230.24(B).

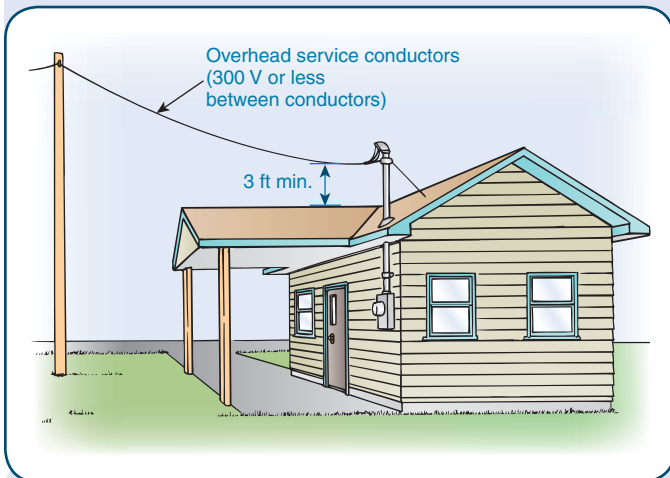

**EXHIBIT 230.19** Overhead service conductor clearance required by 230.24(A), Exception No. 1.

*Exception No. 2: Where the voltage between conductors does not exceed 300 and the roof has a slope of 100 mm in*

300 mm (4 in. in 12 in.) or greater; a reduction in clearance to 900 mm (3 ft) shall be permitted.

Exception No. 2 to 230.24(A) permits a reduction in overhead service conductor clearance above the roof from 8 ft to 3 ft, as illustrated in Exhibit 230.20, where the voltage between conductors does not exceed 300 volts (for example, 120/240-volt and 208Y/120-volt services) and the roof is sloped not less than 4 in. vertically in 12 in. horizontally. Steeply sloped roofs are less likely to be walked on by other than those who have to work on the roof. There are no restrictions on the length of the conductors over the roof.

**EXHIBIT 230.20** Reduction in clearance above a roof as permitted by 230.24(A), Exception No. 2.

**Exception No. 3:** Where the voltage between conductors does not exceed 300, a reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (1) not more than 1.8 m (6 ft) of overhead service conductors, 1.2 m (4 ft) horizontally, pass above the roof overhang, and (2) they are terminated at a through-the-roof raceway or approved support.

Informational Note: See 230.28 for mast supports.

Exception No. 3 to 230.24(A) permits a reduction of overhead service conductor clearances to 18 in. above the roof, as illustrated in Exhibit 230.21. This reduction is for service-mast (through-the-roof) installations where the voltage between conductors does not exceed 300 volts (for example, 120/240-volt and 208Y/120-volt services) and the mast is located within 4 ft of the edge of the roof, measured horizontally. Exception No. 3 applies to overhanging portion of sloped and flat roofs. Not more than 6 ft of conductors is permitted to pass over the roof.

**EXHIBIT 230.21** Reduction in clearance above a roof as permitted by 230.24(A), Exception No. 3.

**Exception No. 4:** The requirement for maintaining the vertical clearance 900 mm (3 ft) from the edge of the roof shall not apply to the final conductor span where the service drop is attached to the side of a building.

Exception No. 4 to 230.24(A) exempts the final span of overhead service conductors attached to the side of a building from the 8-ft and 3-ft clearance requirements, to allow the service conductors to be attached to the building, as illustrated in Exhibit 230.22.

**Exception No. 5:** Where the voltage between conductors does not exceed 300 and the roof area is guarded or isolated, a reduction in clearance to 900 mm (3 ft) shall be permitted.

**(B) Vertical Clearance for Overhead Service Conductors.** Overhead service conductors, where not in excess of 600 volts, nominal, shall have the following minimum clearance from final grade:

- (1) 3.0 m (10 ft) — at the electrical service entrance to buildings, also at the lowest point of the drip loop of the building electrical entrance, and above areas or sidewalks accessible only to pedestrians, measured from

**EXHIBIT 230.22** Clearance of the final span of overhead service conductors, as permitted by 230.24(A), Exception No. 4.

final grade or other accessible surface only for service-drop cables supported on and cabled together with a grounded bare messenger where the voltage does not exceed 150 volts to ground

- (2) 3.7 m (12 ft) — over residential property and driveways, and those commercial areas not subject to truck traffic where the voltage does not exceed 300 volts to ground
- (3) 4.5 m (15 ft) — for those areas listed in the 3.7-m (12-ft) classification where the voltage exceeds 300 volts to ground
- (4) 5.5 m (18 ft) — over public streets, alleys, roads, parking areas subject to truck traffic, driveways on other than residential property, and other land such as cultivated, grazing, forest, and orchard

Exhibit 230.23 illustrates the 10-ft, 12-ft, 15-ft, and 18-ft vertical clearances from ground for overhead service con-

**EXHIBIT 230.23** Clearances in accordance with 230.24(B).

ductors up to 600 volts, as specified by 230.24(B). The voltages given in 230.24(B)(1), (B)(2), and (B)(3) are nominal voltages to ground, not the nominal voltage between circuit conductors as specified in 230.24(A), Exceptions No. 2 and No. 3. A 480Y/277-volt system (277 volts to ground) is covered by the 12-ft clearance requirement in 230.24(B)(2), but overhead service conductors supplied by an ungrounded 480-volt system (considered to be 480 volts to ground) are required to have a 15-ft clearance over commercial areas not subject to truck traffic, in accordance with (B)(3).

**(C) Clearance from Building Openings.** See 230.9.

**(D) Clearance from Swimming Pools.** See 680.8.

**(E) Clearance from Communication Wires and Cables.** Clearance from communication wires and cables shall be in accordance with 800.44(A)(4).

### 230.26 Point of Attachment

The point of attachment of the service-drop conductors to a building or other structure shall provide the minimum clearances as specified in 230.9 and 230.24. In no case shall this point of attachment be less than 3.0 m (10 ft) above finished grade.

### 230.27 Means of Attachment

Multiconductor cables used for overhead service conductors shall be attached to buildings or other structures by fittings identified for use with service conductors. Open conductors shall be attached to fittings identified for use with service conductors or to noncombustible, nonabsorbent insulators securely attached to the building or other structure.

Section 230.27 specifies the means of attachment for overhead service conductors. See 230.51 for mounting and supporting of service cables and individual open service conductors, and 230.54 for connections at service heads.

### 230.28 Service Masts as Supports

Where a service mast is used for the support of service-drop conductors, it shall be of adequate strength or be supported by braces or guys to withstand safely the strain imposed by the service drop. Where raceway-type service masts are used, all raceway fittings shall be identified for use with service masts. Only power service-drop conductors shall be permitted to be attached to a service mast.

The requirements for masts that serve as supports for service-drop conductors are specified in 230.28. Where the service

drop is secured to the mast, a guy wire may be needed to support the mast and provide the required mechanical strength to support the service drop. Communications conductors such as those for cable TV or telephone service are not permitted to be attached to the service mast.

### 230.29 Supports over Buildings

**Service** conductors passing over a roof shall be securely supported by substantial structures. Where practicable, such supports shall be independent of the building.

## III. Underground Service Conductors

### 230.30 Insulation

Service-lateral conductors shall be insulated for the applied voltage.

*Exception: A grounded conductor shall be permitted to be uninsulated as follows:*

- (1) Bare copper used in a raceway.
- (2) Bare copper for direct burial where bare copper is judged to be suitable for the soil conditions.
- (3) Bare copper for direct burial without regard to soil conditions where part of a cable assembly identified for underground use.
- (4) Aluminum or copper-clad aluminum without individual insulation or covering where part of a cable assembly identified for underground use in a raceway or for direct burial.

Aluminum or copper-clad aluminum conductors must be insulated if they are run in a raceway or direct buried, unless they are part of a cable assembly identified for the use.

### 230.31 Size and Rating

**(A) General.** **Underground service** conductors shall have sufficient ampacity to carry the current for the load as calculated in accordance with Article 220 and shall have adequate mechanical strength.

**(B) Minimum Size.** The conductors shall not be smaller than 8 AWG copper or 6 AWG aluminum or copper-clad aluminum.

*Exception: Conductors supplying only limited loads of a single branch circuit — such as small polyphase power, controlled water heaters, and similar loads — shall not be smaller than 12 AWG copper or 10 AWG aluminum or copper-clad aluminum.*

**(C) Grounded Conductors.** The grounded conductor shall not be less than the minimum size required by 250.24(C).

In addition to the minimum size requirement for the grounded conductor referenced in 230.31(C), see 310.15(B)(4) for the allowable ampacity of bare and covered conductors. For further information on sizing the grounded conductor for dwelling services, refer to 310.15(B)(7); for more information on sizing the grounded service conductor for any occupancy, see the commentary following 230.42(C).

### 230.32 Protection Against Damage

Underground **service** conductors shall be protected against damage in accordance with 300.5. **Service** conductors entering a building or other structure shall be installed in accordance with 230.6 or protected by a raceway wiring method identified in 230.43.

### 230.33 Spliced Conductors

**Service** conductors shall be permitted to be spliced or tapped in accordance with 110.14, 300.5(E), 300.13, and 300.15.

## IV. Service-Entrance Conductors

### 230.40 Number of Service-Entrance Conductor Sets

Each service drop, set of overhead service conductors, set of underground service conductors, or service lateral shall supply only one set of service-entrance conductors.

*Exception No. 1: A building with more than one occupancy shall be permitted to have one set of service-entrance conductors for each service, as defined in 230.2, run to each occupancy or group of occupancies. If the number of service disconnect locations for any given classification of service does not exceed six, the requirements of 230.2(E) shall apply at each location. If the number of service disconnect locations exceeds six for any given supply classification, all service disconnect locations for all supply characteristics, together with any branch circuit or feeder supply sources, if applicable, shall be clearly described using suitable graphics or text, or both, on one or more plaques located in an approved, readily accessible location(s) on the building or structure served and as near as practicable to the point(s) of attachment or entry(ies) for each service drop or service lateral, and for each set of overhead or underground service conductors.*

The general requirement of 230.40 is that each service drop, set of overhead service conductors, set of underground ser-

vice conductors, or service-lateral supply only one set of service-entrance conductors. However, if a building has more than one occupancy, such as multifamily dwellings, strip malls, and office buildings, each service drop, set of overhead service conductors, set of underground service conductors, or service lateral is allowed to supply more than one set of service-entrance conductors, provided they are run to each occupancy or group of occupancies. Although the building is supplied by a single service, this provision allows for multiple service disconnecting means locations for each service that supplies a building or structure. From that perspective, one service may be arranged similarly to an installation where a building or structure is supplied by multiple services. This exception does not limit the number of disconnecting means locations supplied by each classification of service.

Where a building is supplied by multiple services, 230.2(E) requires a permanent plaque or directory at each service disconnecting means location with information about the multiple services or other circuits supplying the building and the areas served by each. Because Exception No.1 to 230.40 permits more than one service equipment location on a single building or structure, it requires that the information about the multiple equipment locations be provided at each location in accordance with the provision of 230.2(E). Where there are six or fewer locations for each service supplying a building, a plaque or directory with the information specified by 230.2(E) is required to be installed at each equipment location.

Where the number of service equipment locations for any class of service exceeds six, a master plaque(s) or directory(s) is required to be provided near the point where service drop, overhead service, underground service, or service-lateral conductors attach to or enter a building or structure. The information must describe the multiple service equipment locations using either text or a graphic or a combination. At the individual service equipment locations, the general marking required in 230.70(B) has to be provided.

For example, if a mercantile building has eight storefronts and the building is supplied by a single 208Y/120-volt service, eight sets of service-entrance conductors can be installed, with one set run to each occupancy, and the service equipment at each occupancy can have up to six service disconnecting means in accordance with 230.71(A). Because the number of service disconnecting means locations for this service exceeds six, a permanent plaque(s) with either a diagram of the supply equipment arrangement for the building or text or a combination of the two explaining the multiple supply equipment locations is required. The location of this plaque or display must be readily accessible and acceptable to the authority having jurisdiction.

*Exception No. 2: Where two to six service disconnecting means in separate enclosures are grouped at one location and supply separate loads from one service drop, set of overhead service conductors, set of underground service conductors, or service lateral, one set of service-entrance conductors shall be permitted to supply each or several such service equipment enclosures.*

Exhibits 230.2 through 230.13 provide several examples of service configurations permitted by Exception No. 2 to 230.40. In Exhibit 230.7 and Exhibit 230.10, the multiple sets of service-lateral conductors are treated as a single service lateral in accordance with the first paragraph of 230.2.

*Exception No. 3: A single-family dwelling unit and its accessory structures shall be permitted to have one set of service-entrance conductors run to each from a single service drop, set of overhead service conductors, set of underground service conductors, or service lateral.*

Exception No. 3 to 230.40 permits a second set of service-entrance conductors supplied by a single service drop or lateral at a single-family dwelling unit to also supply another building on the premises, such as a garage or storage shed. The utility meters may be grouped at one location but in this application, the service disconnecting means are not required to be grouped at one location. A service disconnecting means at the dwelling and at the other building is acceptable where this exception is used.

*Exception No. 4: Two-family dwellings, multifamily dwellings, and multiple occupancy buildings shall be permitted to have one set of service-entrance conductors installed to supply the circuits covered in 210.25.*

*Exception No. 5: One set of service-entrance conductors connected to the supply side of the normal service disconnecting means shall be permitted to supply each or several systems covered by 230.82(5) or 230.82(6).*

## **230.41 Insulation of Service-Entrance Conductors**

Service-entrance conductors entering or on the exterior of buildings or other structures shall be insulated.

*Exception: A grounded conductor shall be permitted to be uninsulated as follows:*

- (1) Bare copper used in a raceway or part of a service cable assembly.
- (2) Bare copper for direct burial where bare copper is judged to be suitable for the soil conditions.

- (3) *Bare copper for direct burial without regard to soil conditions where part of a cable assembly identified for underground use.*
- (4) *Aluminum or copper-clad aluminum without individual insulation or covering where part of a cable assembly or identified for underground use in a raceway, or for direct burial.*
- (5) *Bare conductors used in an auxiliary gutter.*

Section 230.41, Exceptions No. 1 through 4, permits bare grounded conductors under the same conditions as permitted in 230.30, Exception, for underground service laterals. Exception No. 5 to 230.41 permits bare grounded conductors in an auxiliary gutter that is used to supplement the space of a metering enclosure, service panelboard, or service switchboard.

### 230.42 Minimum Size and Rating

**(A) General.** The ampacity of the service-entrance conductors before the application of any adjustment or correction factors shall not be less than either 230.42(A)(1) or (A)(2). Loads shall be determined in accordance with Part III, IV, or V of Article 220, as applicable. Ampacity shall be determined from 310.15. The maximum allowable current of busways shall be that value for which the busway has been listed or labeled.

- (1) The sum of the noncontinuous loads plus 125 percent of continuous loads

*Exception: Grounded conductors that are not connected to an overcurrent device shall be permitted to be sized at 100 percent of the continuous and noncontinuous load.*

- (2) The sum of the noncontinuous load plus the continuous load if the service-entrance conductors terminate in an overcurrent device where both the overcurrent device and its assembly are listed for operation at 100 percent of their rating

**(B) Specific Installations.** In addition to the requirements of 230.42(A), the minimum ampacity for ungrounded conductors for specific installations shall not be less than the rating of the service disconnecting means specified in 230.79(A) through (D).

The basic rule in 230.42(B) requires ungrounded service conductors to be sized large enough to carry the calculated load and to have an ampacity not less than the minimum rating of the service disconnecting means required by 230.79(A) through (D).

**(C) Grounded Conductors.** The grounded conductor shall not be smaller than the minimum size as required by 250.24(C).

The reference to 250.24(C) for determining the minimum size grounded service conductor reflects the fact that in addition to its role as a circuit conductor for loads supplied by the service, the grounded service conductor also provides the ground-fault current path from the load end of the service conductors in the service equipment to the transformer or other equipment at which the service conductors receive their supply. This is the same function as the equipment grounding conductor provides in feeder and branch circuits. The normal circuit conductor function cannot be ignored in determining the minimum size of the ground service conductor and the provision of 220.61 has to be applied. Using 220.61 and 250.24(C), the requirement that results in the largest conductor is what is used as the minimum size grounded service conductor. The *Code* of course does not prohibit sizing the grounded conductor simply by using the same size as the ungrounded (hot) service conductors.

In addition, the heating effect of harmonic currents due to nonlinear loads should be considered in the sizing of the neutral conductor of a 3-phase, 4-wire wye system.

### 230.43 Wiring Methods for 600 Volts, Nominal, or Less

Service-entrance conductors shall be installed in accordance with the applicable requirements of this *Code* covering the type of wiring method used and shall be limited to the following methods:

- (1) Open wiring on insulators
- (2) Type IGS cable
- (3) Rigid metal conduit
- (4) Intermediate metal conduit
- (5) Electrical metallic tubing
- (6) Electrical nonmetallic tubing (ENT)
- (7) Service-entrance cables
- (8) Wireways
- (9) Busways
- (10) Auxiliary gutters
- (11) Rigid polyvinyl chloride conduit (PVC)
- (12) Cablebus
- (13) Type MC cable
- (14) Mineral-insulated, metal-sheathed cable
- (15) Flexible metal conduit not over 1.8 m (6 ft) long or liquidtight flexible metal conduit not over 1.8 m (6 ft) long between raceways, or between raceway and service equipment, with equipment bonding jumper routed with the flexible metal conduit or the liquid-

tight flexible metal conduit according to the provisions of 250.102(A), (B), (C), and (E)

- (16) Liquidtight flexible nonmetallic conduit

Section 230.43(15) and (16) permit no more than 6 ft of flexible metal conduit or liquidtight flexible metal conduit to be used as a service wiring method. Because of the high levels of fault energy available on the line side of the service disconnecting means, a bonding jumper must be installed where these raceway types are used for service conductors. The bonding jumper is allowed to be installed inside or outside the raceway, but it must follow the path of the raceway and cannot exceed 6 ft in length. In order to minimize the impedance of the ground fault current return path, the bonding jumper must not be wrapped or spiraled around the flexible conduit.

- (17) High density polyethylene conduit (HDPE)  
 (18) Nonmetallic underground conduit with conductors (NUCC)  
 (19) Reinforced thermosetting resin conduit (RTRC)

### 230.44 Cable Trays

Cable tray systems shall be permitted to support service-entrance conductors. Cable trays used to support service-entrance conductors shall contain only service-entrance conductors and shall be limited to the following methods:

- (1) Type SE cable
- (2) Type MC cable
- (3) Type MI cable
- (4) Type IGS cable
- (5) Single thermoplastic-insulated conductors 1/0 and larger with CT rating

Such cable trays shall be identified with permanently affixed labels with the wording "Service-Entrance Conductors." The labels shall be located so as to be visible after installation and placed so that the service-entrance conductors are able to be readily traced through the entire length of the cable tray.

The requirement for labeling cable trays that contain service-entrance conductors applies to installations where the cable tray contains only service-entrance conductors and to installations where the cable tray contains service-entrance conductors and other conductors as permitted in 230.44, Exception.

*Exception: Conductors, other than service-entrance conductors, shall be permitted to be installed in a cable tray*

*with service-entrance conductors, provided a solid fixed barrier of a material compatible with the cable tray is installed to separate the service-entrance conductors from other conductors installed in the cable tray.*

### 230.46 Spliced Conductors

Service-entrance conductors shall be permitted to be spliced or tapped in accordance with 110.14, 300.5(E), 300.13, and 300.15.

Splices are permitted in service-entrance conductors if the splice meets the requirements referenced in 230.46. Splices must be in an enclosure or be direct buried using a listed underground splice kit. It is common to have an underground service lateral terminate at a terminal box either inside or outside the building. At that point, service conductors may be spliced or run directly to the service equipment.

Splices are permitted where, for example, the cable enters a terminal box and a different wiring method, such as conduit, continues to the service equipment. Tapped sets of conductors are also recognized by this provision and this method is commonly used to supply multiple service disconnecting means installed in separate enclosures as permitted by 230.71(A).

### 230.50 Protection Against Physical Damage

**(A) Underground Service-Entrance Conductors.** Underground service-entrance conductors shall be protected against physical damage in accordance with 300.5.

**(B) All Other Service-Entrance Conductors.** All other service-entrance conductors, other than underground service entrance conductors, shall be protected against physical damage as specified in 230.50(B)(1) or (B)(2).

**(1) Service-Entrance Cables.** Service-entrance cables, where subject to physical damage, shall be protected by any of the following:

- (1) Rigid metal conduit
- (2) Intermediate metal conduit
- (3) Schedule 80 PVC conduit
- (4) Electrical metallic tubing
- (5) Reinforced thermosetting resin conduit (RTRC)
- (6) Other approved means

**(2) Other Than Service-Entrance Cables.** Individual open conductors and cables, other than service-entrance cables, shall not be installed within 3.0 m (10 ft) of grade level or where exposed to physical damage.

*Exception: Type MI and Type MC cable shall be permitted within 3.0 m (10 ft) of grade level where not exposed to*

physical damage or where protected in accordance with 300.5(D).

### 230.51 Mounting Supports

Service-entrance cables or individual open service-entrance conductors shall be supported as specified in 230.51(A), (B), or (C).

**(A) Service-Entrance Cables.** Service-entrance cables shall be supported by straps or other approved means within 300 mm (12 in.) of every service head, gooseneck, or connection to a raceway or enclosure and at intervals not exceeding 750 mm (30 in.).

**(B) Other Cables.** Cables that are not approved for mounting in contact with a building or other structure shall be mounted on insulating supports installed at intervals not exceeding 4.5 m (15 ft) and in a manner that maintains a clearance of not less than 50 mm (2 in.) from the surface over which they pass.

**(C) Individual Open Conductors.** Individual open conductors shall be installed in accordance with Table 230.51(C). Where exposed to the weather, the conductors shall be mounted on insulators or on insulating supports attached to racks, brackets, or other approved means. Where not exposed to the weather, the conductors shall be mounted on glass or porcelain knobs.

### 230.52 Individual Conductors Entering Buildings or Other Structures

Where individual open conductors enter a building or other structure, they shall enter through roof bushings or through the wall in an upward slant through individual, noncombustible, nonabsorbent insulating tubes. Drip loops shall be formed on the conductors before they enter the tubes.

### 230.53 Raceways to Drain

Where exposed to the weather, raceways enclosing service-entrance conductors shall be suitable for use in wet locations

and arranged to drain. Where embedded in masonry, raceways shall be arranged to drain.

The objective of 230.53 is to prevent water from entering electrical equipment through the raceway system. Service raceways exposed to the weather must have raintight fittings and drain holes or other means to preclude water from coming in contact with live parts of electrical equipment. Surface water, rain, or water from poured concrete are problematic for raceways embedded in masonry, and means must be provided for draining and diverting the water from these raceways.

### 230.54 Overhead Service Locations

**(A) Service Head.** Service raceways shall be equipped with a service head at the point of connection to service-drop or overhead service conductors. The service head shall be listed for use in wet locations.

**(B) Service-Entrance Cables Equipped with Service Head or Gooseneck.** Service-entrance cables shall be equipped with a service head. The service head shall be listed for use in wet locations.

Service raceways and service cables are required to be equipped with a raintight service head (weatherhead) that is listed for use in a wet location. Type SE service-entrance cables may be installed without a service head if they are run continuously from a utility pole to metering or service equipment or if they are shaped in a downward direction (forming a “gooseneck”) and sealed by taping and painting, as shown in Exhibit 230.24.

*Exception: Type SE cable shall be permitted to be formed in a gooseneck and taped with a self-sealing weather-resistant thermoplastic.*

**(C) Service Heads and Goosenecks Above Service-Drop or Overhead Service Attachment.** Service heads and goose-

TABLE 230.51(C) Supports

Maximum Volts	Maximum Distance Between Supports		Minimum Clearance			
			Between Conductors		From Surface	
	m	ft	mm	in.	mm	in.
600	2.7	9	150	6	50	2
600	4.5	15	300	12	50	2
300	1.4	4½	75	3	50	2
600*	1.4*	4½*	65*	2½*	25*	1*

\*Where not exposed to weather.

**EXHIBIT 230.24** A service-entrance cable that terminates in a gooseneck without a raintight service head (weatherhead).

necks in service-entrance cables shall be located above the point of attachment of the service-drop or overhead service conductors to the building or other structure.

Service heads and goosenecks are required to be located above the point of attachment to the building or structure for the service drop or overhead service conductors unless such location is not feasible, in which case the service head or gooseneck is permitted to be located not farther than 24 in. from the point of attachment, in accordance with the exception to 230.54(C). Individual conductors should extend in a downward direction, as shown in Exhibit 230.24, or drip loops should be formed so that, where splices are made, they are at the lowest point of the drip loop.

*Exception: Where it is impracticable to locate the service head or gooseneck above the point of attachment, the service head or gooseneck location shall be permitted not farther than 600 mm (24 in.) from the point of attachment.*

**(D) Secured.** Service-entrance cables shall be held securely in place.

**(E) Separately Bushed Openings.** Service heads shall have conductors of different potential brought out through separately bushed openings.

*Exception: For jacketed multiconductor service-entrance cable without splice.*

**(F) Drip Loops.** Drip loops shall be formed on individual conductors. To prevent the entrance of moisture, service-entrance conductors shall be connected to the service-drop or overhead service conductors either (1) below the level of the service head or (2) below the level of the termination of the service-entrance cable sheath.

**(G) Arranged That Water Will Not Enter Service Raceway or Equipment.** Service-entrance and overhead service conductors shall be arranged so that water will not enter service raceway or equipment.

### 230.56 Service Conductor with the Higher Voltage to Ground

On a 4-wire, delta-connected service where the midpoint of one phase winding is grounded, the service conductor having the higher phase voltage to ground shall be durably and permanently marked by an outer finish that is orange in color, or by other effective means, at each termination or junction point.

To warn personnel of a potential connection hazard, an ungrounded service conductor having a higher voltage to ground than the other two ungrounded service conductors is required to be durably marked by an outer finish of orange, such as by painting, colored adhesive tagging, or taping. Marking should be at both the point of connection to the service-drop or lateral conductors and the point of connection to the service disconnecting means. See 110.15 and 408.3(E) for similar “high-leg” marking and phase arrangement requirements.

## V. Service Equipment — General

### 230.62 Service Equipment — Enclosed or Guarded

Energized parts of service equipment shall be enclosed as specified in 230.62(A) or guarded as specified in 230.62(B).

**(A) Enclosed.** Energized parts shall be enclosed so that they will not be exposed to accidental contact or shall be guarded as in 230.62(B).

**(B) Guarded.** Energized parts that are not enclosed shall be installed on a switchboard, panelboard, or control board and guarded in accordance with 110.18 and 110.27. Where energized parts are guarded as provided in 110.27(A)(1) and (A)(2), a means for locking or sealing doors providing access to energized parts shall be provided.

### 230.66 Marking

Service equipment rated at 600 volts or less shall be marked to identify it as being suitable for use as service equipment.

All service equipment shall be listed. Individual meter socket enclosures shall not be considered service equipment.

Service equipment is required to be listed (see definition of *listed* in Article 100) and also is required to bear a marking indicating its suitability for use as service equipment. The marking required by this section is not a field marking. The required marking is applied by the equipment manufacturer, and the marking indicates the equipment meets provisions in the applicable product standard (i.e., panelboard, switchboard, enclosed switch, or other equipment product standard) that enable it to carry a marking indicating its suitability as service equipment. “Suitable for Use as Service Equipment” is a common marking found on equipment that can be used at the service location. “Suitable Only for Use as Service Equipment” is a marking that indicates the grounded conductor or neutral terminal bus is not able to be electrically isolated from the metal equipment enclosure. This feature precludes most feeder applications for this equipment where the equipment grounding terminals and the grounded conductor terminals are required to be electrically isolated. A similar requirement is contained in 225.36 for outside feeder and branch-circuit disconnecting means.

## VI. Service Equipment — Disconnecting Means

### 230.70 General

Means shall be provided to disconnect all conductors in a building or other structure from the service-entrance conductors.

**(A) Location.** The service disconnecting means shall be installed in accordance with 230.70(A)(1), (A)(2), and (A)(3).

No maximum distance between the point of entrance of service conductors to a readily accessible location for the installation of a service disconnecting means is specified by 230.71(A). The authority enforcing this *Code* or AHJ has the responsibility for, and is charged with, making the decision on how far inside the building the service-entrance conductors are allowed to travel to the service disconnecting means. The length of service-entrance conductors should be kept to a minimum inside buildings, because power utilities provide limited overcurrent protection. In the event of a fault, the service conductors could ignite nearby combustible materials.

Some local jurisdictions have adopted ordinances that allow service-entrance conductors to run within the building up to a specified length to terminate at the disconnecting means. The authority having jurisdiction may permit service

conductors to bypass fuel storage tanks or gas meters and the like, permitting the service disconnecting means to be located in a readily accessible location.

However, if the authority judges the distance as being excessive, the disconnecting means may be required to be located on the outside of the building or near the building at a readily accessible location that is not necessarily nearest the point of entrance of the conductors. See also 230.6 and Exhibit 230.15 for conductors considered to be outside a building.

See 404.8(A) for mounting-height restrictions for switches and for circuit breakers used as switches.

**(1) Readily Accessible Location.** The service disconnecting means shall be installed at a readily accessible location either outside of a building or structure or inside nearest the point of entrance of the service conductors.

**(2) Bathrooms.** Service disconnecting means shall not be installed in bathrooms.

**(3) Remote Control.** Where a remote control device(s) is used to actuate the service disconnecting means, the service disconnecting means shall be located in accordance with 230.70(A)(1).

**(B) Marking.** Each service disconnect shall be permanently marked to identify it as a service disconnect.

**(C) Suitable for Use.** Each service disconnecting means shall be suitable for the prevailing conditions. Service equipment installed in hazardous (classified) locations shall comply with the requirements of Articles 500 through 517.

### 230.71 Maximum Number of Disconnects

**(A) General.** The service disconnecting means for each service permitted by 230.2, or for each set of service-entrance conductors permitted by 230.40, Exception No. 1, 3, 4, or 5, shall consist of not more than six switches or sets of circuit breakers, or a combination of not more than six switches and sets of circuit breakers, mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard. There shall be not more than six sets of disconnects per service grouped in any one location.

For the purpose of this section, disconnecting means installed as part of listed equipment and used solely for the following shall not be considered a service disconnecting means:

- (1) Power monitoring equipment
- (2) Surge-protective device(s)
- (3) Control circuit of the ground-fault protection system
- (4) Power-operable service disconnecting means

Section 230.71(A) specifies the maximum number of disconnects permitted as the disconnecting means for the service conductors that supply the building or structure. One set of service-entrance conductors, either overhead or underground, is permitted to supply two to six service disconnecting means in lieu of a single main disconnect. A single-occupancy building can have up to six disconnects for each set of service-entrance conductors. Multiple-occupancy buildings (residential or other than residential) can be provided with one main service disconnect or up to six main disconnects for each set of service-entrance conductors.

Multiple-occupancy buildings may have service-entrance conductors run to each occupancy, and each such set of service-entrance conductors may have from one to six disconnects (see 230.40, Exception No. 1).

Exhibit 230.25 shows a single enclosure for grouping service equipment that consists of six circuit breakers or six fused switches. This arrangement does not require a single main service disconnecting means. Six separate enclosures also would be permitted as the service equipment. Where factory-installed switches that disconnect power to surge protective devices and power monitoring equipment are included as part of listed equipment, the last sentence of 230.71(A) specifies that the disconnect switch for such equipment installed as part of the listed equipment does *not* count as one of the six service disconnecting means permitted by 230.71(A). The disconnecting means for the control circuit of ground-fault protection equipment or for a power-operable service disconnecting means are also not considered to be service disconnecting means where such disconnecting means are installed as a component of listed equipment.

**EXHIBIT 230.25** A service equipment enclosure that groups six service disconnecting means.

**(B) Single-Pole Units.** Two or three single-pole switches or breakers, capable of individual operation, shall be permitted on multiwire circuits, one pole for each ungrounded conductor, as one multipole disconnect, provided they are equipped with identified handle ties or a master handle to disconnect all conductors of the service with no more than six operations of the hand.

Informational Note: See 408.36, Exception No. 1 and Exception No. 3, for service equipment in certain panelboards, and see 430.95 for service equipment in motor control centers.

## 230.72 Grouping of Disconnects

**(A) General.** The two to six disconnects as permitted in 230.71 shall be grouped. Each disconnect shall be marked to indicate the load served.

*Exception: One of the two to six service disconnecting means permitted in 230.71, where used only for a water pump also intended to provide fire protection, shall be permitted to be located remote from the other disconnecting means. If remotely installed in accordance with this exception, a plaque shall be posted at the location of the remaining grouped disconnects denoting its location.*

The water pump in 230.72(A), Exception, is not the fire pump covered by the requirements of Article 695; rather, it is a water pump used for normal water supply and also for fire protection. This application is used in agricultural settings and permits separation of the water pump disconnect so it can remain operational in the event of a problem at the location of the other service disconnecting means.

**(B) Additional Service Disconnecting Means.** The one or more additional service disconnecting means for fire pumps, emergency systems, legally required standby, or optional standby services permitted by 230.2 shall be installed remote from the one to six service disconnecting means for normal service to minimize the possibility of simultaneous interruption of supply.

Section 230.2(A) permits separate services, where necessary, for fire pumps (with one to six disconnects) or for emergency, legally required standby, or optional standby systems (with one to six disconnects), in addition to the one to six disconnects for the normal building service. Reliability of power to important safety equipment or systems, such as fire pumps and building emergency power systems, is enhanced by locating the disconnecting means for such equipment and systems at locations remote from the normal service disconnecting means. Events including electrical

equipment failure or failure of other building systems or structures so as to imperil the electrical equipment and inadvertent operation of disconnecting means are concerns addressed by this separation of service requirement. The authority having jurisdiction is responsible for approving what will be considered as a suitably “remote” location for the additional service disconnecting means. Requirements in Articles 695 and 700 as well as in other standards such as NFPA 110, *Standard for Emergency and Standby Power Systems*, contain similar requirements that are focused on a high degree of reliability for power to safety equipment and systems. The disconnecting means allowed for the equipment or systems covered by 230.72(B) are in addition to the one or more disconnecting means for the normal supply. The separate services are required to be installed in accordance with all the applicable requirements of Article 230 including the identification requirement specified in 230.2(E).

**(C) Access to Occupants.** In a multiple-occupancy building, each occupant shall have access to the occupant’s service disconnecting means.

The requirement of 230.72(C) is specific to multiple-occupancy buildings because the different units are generally independent of each other and access to the service disconnecting means may be precluded because of locked doors or other physical impediments that are inherent to this type of building. Unless electric service and maintenance are provided by and under continuous supervision of the building management, the occupants of a multiple-occupancy building must have ready access to their service disconnecting means and this feature has to be incorporated into the building service equipment layout. Section 240.24(B) contains a similar requirement for access to service, feeder and branch circuit overcurrent protective devices.

*Exception: In a multiple-occupancy building where electric service and electrical maintenance are provided by the building management and where these are under continuous building management supervision, the service disconnecting means supplying more than one occupancy shall be permitted to be accessible to authorized management personnel only.*

### 230.74 Simultaneous Opening of Poles

Each service disconnect shall simultaneously disconnect all ungrounded service conductors that it controls from the premises wiring system.

### 230.75 Disconnection of Grounded Conductor

Where the service disconnecting means does not disconnect the grounded conductor from the premises wiring, other

means shall be provided for this purpose in the service equipment. A terminal or bus to which all grounded conductors can be attached by means of pressure connectors shall be permitted for this purpose. In a multisection switchboard, disconnects for the grounded conductor shall be permitted to be in any section of the switchboard, provided any such switchboard section is marked.

Section 230.75 requires provisions at the service equipment for disconnecting the grounded conductor from the premises wiring. This disconnection does not have to be by operation of the service disconnecting means. Disconnection can be, and most commonly is, accomplished by manually removing the grounded conductor from the bus or terminal bar to which it is lugged or bolted. This location is often referred to as the *neutral disconnect link*.

Manufacturers design neutral terminal bars for service equipment so that grounded conductors must be cut to be attached; that is, the grounded conductor cannot be run straight through the service equipment without a means of disconnection from the premises wiring.

### 230.76 Manually or Power Operable

The service disconnecting means for ungrounded service conductors shall consist of one of the following:

- (1) A manually operable switch or circuit breaker equipped with a handle or other suitable operating means
- (2) A power-operated switch or circuit breaker, provided the switch or circuit breaker can be opened by hand in the event of a power supply failure

### 230.77 Indicating

The service disconnecting means shall plainly indicate whether it is in the open (off) or closed (on) position.

### 230.79 Rating of Service Disconnecting Means

The service disconnecting means shall have a rating not less than the calculated load to be carried, determined in accordance with Part III, IV, or V of Article 220, as applicable. In no case shall the rating be lower than specified in 230.79(A), (B), (C), or (D).

**(A) One-Circuit Installations.** For installations to supply only limited loads of a single branch circuit, the service disconnecting means shall have a rating of not less than 15 amperes.

**(B) Two-Circuit Installations.** For installations consisting of not more than two 2-wire branch circuits, the service disconnecting means shall have a rating of not less than 30 amperes.

**(C) One-Family Dwellings.** For a one-family dwelling, the service disconnecting means shall have a rating of not less than 100 amperes, 3-wire.

**(D) All Others.** For all other installations, the service disconnecting means shall have a rating of not less than 60 amperes.

Three-wire services that supply one-family dwellings are required to be installed using wire with the capacity to supply a 100-ampere service for all single-family dwellings.

A conductor ampacity of 60 amperes is permitted for other loads. Smaller sizes are permitted down to 14 AWG copper (12 AWG aluminum) for installations with one circuit. Two-circuit installations must have a rating of at least 30 amperes. Exhibit 230.26, referred to in the commentary following Exception No. 3 to 230.90(A), illustrates the conductor sizing requirements of 230.79 for ungrounded service-entrance conductors. A single service disconnecting means is required to have a rating of not less than the load to be supplied.

### 230.80 Combined Rating of Disconnects

Where the service disconnecting means consists of more than one switch or circuit breaker, as permitted by 230.71, the combined ratings of all the switches or circuit breakers used shall not be less than the rating required by 230.79.

Section 230.71(A) permits up to six individual switches or circuit breakers, mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard or several switchboards, to serve as the required service disconnecting means at any one location. Section 230.80 refers to situations in which more than one switch or circuit breaker is used as the disconnecting means and indicates that the combined rating of all the switches or circuit breakers used cannot be less than the rating required for a single switch or circuit breaker.

Section 230.90 requires an overcurrent device to provide overload protection in each ungrounded service conductor. A single overcurrent device must have a rating or setting that is not higher than the allowable ampacity of the service conductors. However, Exception No. 3 to 230.90(A) allows not more than six circuit breakers or six sets of fuses to be considered the overcurrent device. None of these individual overcurrent devices can have a rating or setting higher than the ampacity of the service conductors.

In complying with these rules, it is possible for the total of the six overcurrent devices to be greater than the rating of the service-entrance conductors. However, the size of the service-entrance conductors is required to be adequate for

the computed load only, and each individual service disconnecting means is required to be large enough for the individual load it supplies. See the commentary following 230.90(A), Exception No. 3.

### 230.81 Connection to Terminals

The service conductors shall be connected to the service disconnecting means by pressure connectors, clamps, or other approved means. Connections that depend on solder shall not be used.

### 230.82 Equipment Connected to the Supply Side of Service Disconnect

Only the following equipment shall be permitted to be connected to the supply side of the service disconnecting means:

- (1) Cable limiters or other current-limiting devices.

Cable limiters or other current-limiting devices are permitted by 230.82(1) to be applied ahead of the service disconnecting means for the following reasons:

1. Individually isolates faulted cable(s) from the remainder of the circuit or paralleled set of conductors.
  2. Continuity of service is maximized even though one or more cables are faulted.
  3. The possibility of severe equipment damage or burn-down as a result of a fault on the service conductors is reduced.
  4. The current-limiting feature of cable limiters can be used to provide protection against high short-circuit currents for services and to provide compliance with 110.10.
- (2) Meters and meter sockets nominally rated not in excess of 600 volts, provided all metal housings and service enclosures are grounded in accordance with Part VII and bonded in accordance with Part V of Article 250.
  - (3) Meter disconnect switches nominally rated not in excess of 600 volts that have a short-circuit current rating equal to or greater than the available short-circuit current, provided all metal housings and service enclosures are grounded in accordance with Part VII and bonded in accordance with Part V of Article 250. A meter disconnect switch shall be capable of interrupting the load served.

Meter sockets and meter disconnect switches are permitted by 230.82(2) and (3) to be connected on the supply side of the service disconnecting means. The meter disconnect is a

load-break disconnect switch designed to interrupt the service load on 480Y/277-volt services with self-contained meter sockets. The meter disconnect is not the service disconnecting means. The purpose of the meter disconnect switch is to facilitate meter change, maintenance, or disconnecting of the service. Section 230.82(3) requires meter disconnect switches to have a short-circuit current rating that is not less than the available short-circuit current at the line terminals of the meter disconnect switch.

Self-contained meters do not have external potential transformers or current transformers. The load current of the service travels through the meter itself. Neither the self-contained meter nor the meter bypass switch in the meter socket is designed to break the load current on a 480Y/277-volt system.

Self-contained meters or internal meter bypass switches should not be used to break the load current of a service having a voltage of over 150 volts to ground, because a hazardous arc could be generated. Arcs generated at voltages greater than 150 volts are considered self-sustaining and can transfer from the energized portions of the equipment to the grounded portions of the equipment.

An arc created while breaking load current on a 480Y/277-volt system (277 volts to ground) could transfer to the grounded equipment enclosure, creating a high-energy arcing ground fault and arc flash that could develop into a 3-phase short circuit. This hazardous arcing could burn down the meter socket and injure the person performing the work.

- (4) Instrument transformers (current and voltage), impedance shunts, load management devices, surge arresters, and Type 1 surge-protective devices.
- (5) Taps used only to supply load management devices, circuits for standby power systems, fire pump equipment, and fire and sprinkler alarms, if provided with service equipment and installed in accordance with requirements for service-entrance conductors.

Systems such as emergency lighting, fire alarms, fire pumps, standby power, and sprinkler alarms are permitted by 230.82(5) to be connected ahead of the normal service disconnecting means only if such systems are provided with a separate disconnecting means and overcurrent protection.

- (6) Solar photovoltaic systems, fuel cell systems, or interconnected electric power production sources.
- (7) Control circuits for power-operable service disconnecting means, if suitable overcurrent protection and disconnecting means are provided.

- (8) Ground-fault protection systems or Type 2 surge-protective devices, where installed as part of listed equipment, if suitable overcurrent protection and disconnecting means are provided.

Type 2 surge protective devices are permitted by 230.82(5) to be connected on the line side of the service disconnecting means. Such applications are permitted only in listed equipment, and the conductors connected to the surge protective device must have a disconnecting means and overcurrent protection. Field connection of these devices to the line terminals of the service equipment is not permitted.

- (9) Connections used only to supply listed communications equipment under the exclusive control of the serving electric utility, if suitable overcurrent protection and disconnecting means are provided. For installations of equipment by the serving electric utility, a disconnecting means is not required if the supply is installed as part of a meter socket, such that access can only be gained with the meter removed.

The listed communications equipment covered by this exception includes equipment associated with Smart Grid applications (two-way communications between the premises electrical system and the supplying utility) and equipment associated with premises-powered broadband communication systems. Where building safety functions such as automatic or manual transmission of fire, security, medical, or 911 messages are dependent on premises-powered communications equipment, this permission to connect ahead of the service disconnecting means enhances the reliability of the power supply. Opening (turning off) of the service disconnecting means may occur for any number of reasons including planned shutdowns, building emergencies, or vandalism. Regardless of the reason, power for the communications system remains uninterrupted.

## VII. Service Equipment — Overcurrent Protection

### 230.90 Where Required

Each ungrounded service conductor shall have overload protection.

Service equipment constitutes the main control and means of cutoff of the electrical supply to the premises wiring system. At this point, an overcurrent device, usually a circuit breaker or a fuse, must be installed in series with each un-

grounded service conductor to provide overload protection only.

The service overcurrent device does not protect the service conductors under short-circuit or ground-fault conditions on the line side of the disconnect. Protection against ground faults and short circuits is provided by the special requirements for service conductor protection and the location of the conductors.

On multiwire circuits, two or three single-pole switches or circuit breakers that are capable of individual operation are permitted as one protective device. This allowance is acceptable, provided the switches or circuit breakers are equipped with handle ties or a master handle, so that all ungrounded conductors of a service can be disconnected with not more than six operations of the hand, per 230.71(B).

**(A) Ungrounded Conductor.** Such protection shall be provided by an overcurrent device in series with each ungrounded service conductor that has a rating or setting not higher than the allowable ampacity of the conductor. A set of fuses shall be considered all the fuses required to protect all the ungrounded conductors of a circuit. Single-pole circuit breakers, grouped in accordance with 230.71(B), shall be considered as one protective device.

*Exception No. 1: For motor-starting currents, ratings that comply with 430.52, 430.62, and 430.63 shall be permitted.*

The service overcurrent protective device for a load that includes motors as well as lighting or a lighting and appliance load is subject to the motor starting currents for all of the motors within a building. This exception allows the service overcurrent protective device to be sized using the requirements of Article 430 to accommodate the motor starting and running current plus the other loads within the building. All of the building loads are determined in accordance with Article 220, and the service conductors and overcurrent protective device must be sized to carry that load. Overcurrent protective devices for motor loads are permitted to have a rating or setting that exceeds the allowable ampacity of the circuit conductors, and this exception extends that permission to the service overcurrent protective device. For an individual motor, the rating is specified by 430.52; for two or more motors, the rating is specified by 430.62; and for a motor(s) load plus lighting and appliance load, the rating is specified by 430.63.

#### Calculation Example

Determine the minimum-size service conductors to supply a 100-ampere lighting and appliance load plus three squirrel-cage induction motors rated 460 volts, 3 phase, code letter F,

service factor 1.15, 40°C, full-voltage starting one 100-hp and two 25-hp motors on a 480-volt, 3-phase system.

#### Solution

**STEP 1.** Calculate the conductor loads. The full-load current of the 100-hp motor is 124 amperes (from Table 430.250). The full-load current of each 25-hp motor is 34 amperes (from Table 430.250). The service-entrance conductors are calculated at 125 percent of 124 amperes (155 amperes) plus two motors at 34 amperes each (68 amperes), for a total of 223 amperes (see 430.24). The motor load of 223 amperes plus the lighting and appliance load of 100 amperes equals a total load of 323 amperes. Based on this calculation, the service-entrance conductors cannot be smaller than 400-kcmil copper or 600-kcmil aluminum [(see Table 310.15(B)(16)].

**STEP 2.** Determine the overcurrent protection. The maximum rating of the service overcurrent protective device is based on the lighting and appliance loads calculated in accordance with Article 220 plus the largest motor branch-circuit overcurrent device plus the sum of the other full-load motor currents.

Using an inverse-time circuit breaker (see Table 430.52), 250 percent of 124 amperes (100-hp motor) is 310 amperes. The next standard size allowed is 350 amperes plus 2 times 34 amperes, for a total of 418 amperes, plus the lighting and appliance load (100 amperes), for a total of 518 amperes. Because going up to the next standard-size overcurrent device is not permitted by 430.62, the next lower standard size is 500 amperes. See 240.6 and 430.63 for feeder overcurrent device rating.

*Exception No. 2: Fuses and circuit breakers with a rating or setting that complies with 240.4(B) or (C) and 240.6 shall be permitted.*

Where the conductor ampacity does not correspond to the standard ampere rating of a circuit breaker or fuse, this exception permits the next-larger-size circuit breaker or fuse to be installed. The provision to “round up” is limited by 240.4(B) to ratings not exceeding 800 amperes in accordance with 240.4(B)(3). This provision only permits rounding up to the next standard size fuse or circuit breaker rating and does not permit the load to exceed the allowable ampacity of the service conductors. See 240.6 for standard ampere ratings of fuses and circuit breakers.

#### Application Example

The calculated load for a service is 350 amperes. The ampacity of a 500-kcmil, Type XHHW copper conductor is 380

amperes [from Table 310.15(B)(16)], and the conductor is allowed to be protected by a 400-ampere fuse or circuit breaker in accordance with 240.4(B). The rating of the fuse or circuit breaker is based on the ampacity of the service conductor, not on the rating of the service disconnect switch.

In this example, a 400-ampere fuse or circuit breaker may be considered properly sized for the protection of 500-kcmil, Type XHHW copper service conductors. If the service disconnecting means [see Exception No. 3 to 230.90(A)] consists of six circuit breakers or six sets of fuses, the combined ratings must not be less than the rating required for a single switch or circuit breaker, in accordance with 230.80. See the commentary following 230.80.

*Exception No. 3: Two to six circuit breakers or sets of fuses shall be permitted as the overcurrent device to provide the overload protection. The sum of the ratings of the circuit breakers or fuses shall be permitted to exceed the ampacity of the service conductors, provided the calculated load does not exceed the ampacity of the service conductors.*

The combined rating of circuit breakers or fuses (service overcurrent protective devices) is permitted by this exception to be greater than the ampacity of the service conductors. If multiple switches/overcurrent protective devices are used as the disconnecting means, the ampacity of the service conductors must be equal to or greater than the load calculated in accordance with Article 220; however, the conductor ampacity is not required to be equal to or greater than the combined rating of the multiple service overcurrent protective devices. The combined rating of service disconnecting means is covered in 230.80.

The combined ratings of the five overcurrent protective devices (350 amperes) shown in Exhibit 230.26 exceed the ampacity of the service-entrance conductors (310 amperes) that is permitted by 230.90(A), Exception No. 3. As specified in this exception, the ampacity of the service-entrance conductors is sufficient to carry the calculated load. The combined rating of the five service disconnecting means also meets the provisions of 230.80, which requires that the combined rating (350 amperes) be not less than the calculated load (305 amperes), the minimum size required for the service overcurrent protective device specified by 240.4 and 230.80. In addition, the rating of the equipment (panelboard) in which the five overcurrent protective devices/service disconnecting means are installed cannot be less than the calculated loads in accordance with the requirements of 408.30. This exception allows for some design flexibility by not requiring the sum of the ratings to be equal to or less than the ampacity of the service-entrance conductors.

For example, the calculated load supplied by the two 80

**EXHIBIT 230.26** An example in which the combined ratings of the five overcurrent devices are permitted to exceed the ampacity of the service conductors.

ampere devices shown in this exhibit may be 73 amperes. Section 240.6 identifies 70 amperes and 80 amperes as standard OCPD sizes. A 70-ampere device is too small, but an 80-ampere device can be used in accordance with 240.4. The feeder conductors supplied by the 80-ampere device are required to have an ampacity not less than the calculated load, which in this example is 73 amperes.

*Exception No. 4: Overload protection for fire pump supply conductors shall comply with 695.4(B)(2)(a).*

*Exception No. 5: Overload protection for 120/240-volt, 3-wire, single-phase dwelling services shall be permitted in accordance with the requirements of 310.15(B)(6).*

**(B) Not in Grounded Conductor.** No overcurrent device shall be inserted in a grounded service conductor except a circuit breaker that simultaneously opens all conductors of the circuit.

### 230.91 Location

The service overcurrent device shall be an integral part of the service disconnecting means or shall be located immediately adjacent thereto.

### 230.92 Locked Service Overcurrent Devices

Where the service overcurrent devices are locked or sealed or are not readily accessible to the occupant, branch-circuit or feeder overcurrent devices shall be installed on the load side, shall be mounted in a readily accessible location, and shall be of lower ampere rating than the service overcurrent device.

### 230.93 Protection of Specific Circuits

Where necessary to prevent tampering, an automatic overcurrent device that protects service conductors supplying

only a specific load, such as a water heater, shall be permitted to be locked or sealed where located so as to be accessible.

### 230.94 Relative Location of Overcurrent Device and Other Service Equipment

The overcurrent device shall protect all circuits and devices.

*Exception No. 1: The service switch shall be permitted on the supply side.*

*Exception No. 2: High-impedance shunt circuits, surge arresters, Type 1 surge-protective devices, surge-protective capacitors, and instrument transformers (current and voltage) shall be permitted to be connected and installed on the supply side of the service disconnecting means as permitted by 230.82.*

*Exception No. 3: Circuits for load management devices shall be permitted to be connected on the supply side of the service overcurrent device where separately provided with overcurrent protection.*

*Exception No. 4: Circuits used only for the operation of fire alarm, other protective signaling systems, or the supply to fire pump equipment shall be permitted to be connected on the supply side of the service overcurrent device where separately provided with overcurrent protection.*

*Exception No. 5: Meters nominally rated not in excess of 600 volts shall be permitted, provided all metal housings and service enclosures are grounded.*

*Exception No. 6: Where service equipment is power operable, the control circuit shall be permitted to be connected ahead of the service equipment if suitable overcurrent protection and disconnecting means are provided.*

### 230.95 Ground-Fault Protection of Equipment

Ground-fault protection of equipment shall be provided for solidly grounded wye electric services of more than 150 volts to ground but not exceeding 600 volts phase-to-phase for each service disconnect rated 1000 amperes or more. The grounded conductor for the solidly grounded wye system shall be connected directly to ground through a grounding electrode system, as specified in 250.50, without inserting any resistor or impedance device.

The rating of the service disconnect shall be considered to be the rating of the largest fuse that can be installed or the highest continuous current trip setting for which the actual overcurrent device installed in a circuit breaker is rated or can be adjusted.

The provisions of 230.95 covering the ground-fault protection of equipment were first required in the 1971 *Code* due

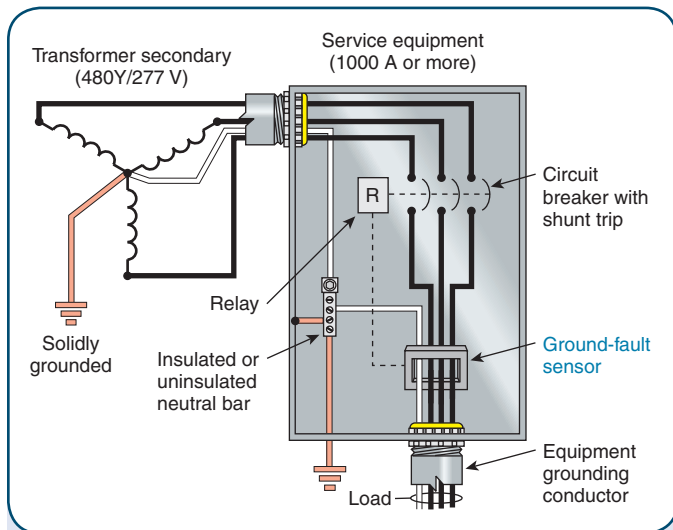

to the unusually high number of equipment burndowns reported on large capacity 480Y/277-volt solidly grounded services. This section requires ground-fault protection of equipment for each service disconnecting means rated 1000 amperes or more where the supply system is solidly grounded, wye-connected, and operates at more than 150 volts to ground and not more than 600 volts phase to phase. See the definition of *ground-fault protection of equipment* in Article 100. Systems operating at 480Y/277 volts were cited in the original substantiation for this requirement, but there are other solidly grounded, wye-connected systems (i.e., 600Y/347) that are covered within the parameters specified by this section. This requirement does not apply to systems where the grounded conductor is not solidly grounded, as is the case with high-impedance grounded neutral systems covered in 250.36.

Ground-fault protection of services does not protect the conductors on the supply side of the service disconnecting means, but it is designed to provide protection from line-to-ground faults that occur on the load side of the service disconnecting means. An alternative to installing ground-fault protection may be to provide multiple disconnects rated less than 1000 amperes. For instance, up to six 800-ampere disconnecting means may be used, and in that case ground-fault protection would not be required. Informational Note No. 2 to 230.95(C) recognizes that ground-fault protection may be desirable at lesser amperages on solidly grounded systems for voltages exceeding 150 volts to ground but not exceeding 600 volts phase to phase.

In addition to providing ground-fault protection, engineering studies are recommended to determine the circuit impedance and short-circuit currents that would be available at the supply terminals, so that equipment and overcurrent protection of the proper interrupting rating are used. See 110.9 and 110.10 for details on interrupting rating and circuit impedance.

The two basic types of ground-fault equipment protectors are illustrated in Exhibits 230.27 and 230.28. In Exhibit 230.27, the ground-fault sensor is installed around all the circuit conductors, and a stray current on a line-to-ground fault sets up an unbalance of the currents flowing in individual conductors installed through the ground-fault sensor. When this current exceeds the setting of the ground-fault sensor, the shunt trip operates and opens the circuit breakers.

The ground-fault sensor illustrated in Exhibit 230.28 is installed around the bonding jumper only. When an unbalanced current from a line-to-ground fault occurs, the current flows through the bonding jumper and the shunt trip causes the circuit breaker to operate, removing the load from the line. See also 250.24(A)(4), which permits a grounding electrode conductor connection to the equipment grounding terminal bar or bus.

**EXHIBIT 230.27** A ground-fault sensor encircling all circuit conductors, including the neutral.

**EXHIBIT 230.28** A ground-fault sensor encircling only the bonding jumper conductor.

*Exception: The ground-fault protection provisions of this section shall not apply to a service disconnect for a continuous industrial process where a nonorderly shutdown will introduce additional or increased hazards.*

Unplanned interruption of power to some industrial processes results in a hazard that has life safety or catastrophic failure results more significant than the electrical hazard mitigated by this requirement. In addition, 695.6(H) prohibits fire pumps from being protected by ground-fault protection of equipment type devices. The use of high-impedance grounded neutral systems as covered in 250.36 is a means to

main continuity of power where the supply system is 3-phase, 4-wire, wye-connected and no line-to-neutral loads are supplied.

**(A) Setting.** The ground-fault protection system shall operate to cause the service disconnect to open all ungrounded conductors of the faulted circuit. The maximum setting of the ground-fault protection shall be 1200 amperes, and the maximum time delay shall be one second for ground-fault currents equal to or greater than 3000 amperes.

The maximum setting for ground-fault sensors is 1200 amperes, per 230.95(A). There is no minimum setting, but settings at low levels can increase the likelihood of unwanted shutdowns. The requirements of 230.95 also place a restriction on fault currents greater than 3000 amperes and limit the duration of the fault to not more than 1 second. This restriction minimizes the amount of damage done by an arcing fault, which is directly proportional to the time the arcing fault is allowed to burn.

Care should be taken to ensure that interconnecting multiple supply systems does not negate proper sensing by the ground-fault protection equipment. A careful engineering study must be made to ensure that fault currents do not take parallel paths to the supply system, thereby bypassing the ground-fault detection device. See 215.10, 240.13, 517.17, and 705.32 for further requirements covering ground-fault protection of equipment.

**(B) Fuses.** If a switch and fuse combination is used, the fuses employed shall be capable of interrupting any current higher than the interrupting capacity of the switch during a time that the ground-fault protective system will not cause the switch to open.

**(C) Performance Testing.** The ground-fault protection system shall be performance tested when first installed on site. The test shall be conducted in accordance with instructions that shall be provided with the equipment. A written record of this test shall be made and shall be available to the authority having jurisdiction.

Section 230.95(C) specifies the requirements for testing ground-fault protection systems. The requirement for ground-fault protection system performance testing is a result of numerous reports of ground-fault protection systems that were improperly wired and could not or did not provide the intended protection. This section and third-party testing organizations that evaluate GFPE equipment require a set of performance testing instructions to be supplied with the

equipment. The third-party testing organization evaluates the performance testing instructions for this equipment. Listed GFPE equipment that is not installed and tested as specified in the product's installation and use instructions does not comply with 110.3(B).

Informational Note No. 1: Ground-fault protection that functions to open the service disconnect affords no protection from faults on the line side of the protective element. It serves only to limit damage to conductors and equipment on the load side in the event of an arcing ground fault on the load side of the protective element.

Informational Note No. 2: This added protective equipment at the service equipment may make it necessary to review the overall wiring system for proper selective overcurrent protection coordination. Additional installations of ground-fault protective equipment may be needed on feeders and branch circuits where maximum continuity of electric service is necessary.

Informational Note No. 3: Where ground-fault protection is provided for the service disconnect and interconnection is made with another supply system by a transfer device, means or devices may be needed to ensure proper ground-fault sensing by the ground-fault protection equipment.

Informational Note No. 4: See 517.17(A) for information on where an additional step of ground-fault protection is required for hospitals and other buildings with critical areas or life support equipment.

## VIII. Services Exceeding 600 Volts, Nominal

### 230.200 General

Service conductors and equipment used on circuits exceeding 600 volts, nominal, shall comply with all the applicable provisions of the preceding sections of this article and with the following sections that supplement or modify the preceding sections. In no case shall the provisions of Part VIII apply to equipment on the supply side of the service point.

Informational Note: For clearances of conductors of over 600 volts, nominal, see ANSI C2-2007, *National Electrical Safety Code*.

Where services rated over 600 volts supply utility-owned and utility-maintained transformers, the underground conductors (including those rising up the pole) on the line side and load side of the transformer up to the underground enclosure at which the *service point* is established are *service lateral* conductors. Only those conductors on the load side of the service point connection are subject to the requirements of the *NEC*. The service point is a specific location where the supply conductors of the electric utility and the customer-owned (premises wiring) conductors connect.

Exhibit 230.29 depicts an installation where the transformer and service lateral to the service point are owned by the electric utility. The transformer secondary conductors between the service point (separate connection point outside of the transformer in this scenario) and the service disconnecting means at the building are *underground service conductors* until the point at which they enter the building. From that point to the termination in the service equipment they are *service-entrance conductors*. In the installation depicted in Exhibit 230.30, the service disconnecting means is located at the customer-owned transformer primary.

**EXHIBIT 230.29** Service rated over 600 volts supplied by a utility-owned transformer.

**EXHIBIT 230.30** Service rated over 600 volts supplying a customer-owned transformer.

conductors that connect the service point (at the top of the pole), the service disconnecting means, and the service/transformer overcurrent protective device are underground service conductors. The conductors between the transformer secondary and the line side of the building disconnecting means are *feeders* and are subject to the requirements for outside conductors connected to a transformer secondary contained in 240.21(C)(4). Conductors (not shown) on the load side of the building disconnecting means are also feeders. Each building or structure is required to have a disconnecting means, in accordance with 225.31.

### 230.202 Service-Entrance Conductors

Service-entrance conductors to buildings or enclosures shall be installed to conform to 230.202(A) and (B).

**(A) Conductor Size.** Service-entrance conductors shall not be smaller than 6 AWG unless in multiconductor cable. Multiconductor cable shall not be smaller than 8 AWG.

**(B) Wiring Methods.** Service-entrance conductors shall be installed by one of the wiring methods covered in 300.37 and 300.50.

### 230.204 Isolating Switches

**(A) Where Required.** Where oil switches or air, oil, vacuum, or sulfur hexafluoride circuit breakers constitute the service disconnecting means, an isolating switch with visible break contacts shall be installed on the supply side of the disconnecting means and all associated service equipment.

*Exception: An isolating switch shall not be required where the circuit breaker or switch is mounted on removable truck panels or metal-enclosed switchgear units where both of the following conditions apply:*

- (1) *Cannot be opened unless the circuit is disconnected.*
- (2) *Where all energized parts are automatically disconnected when the circuit breaker or switch is removed from the normal operating position.*

**(B) Fuses as Isolating Switch.** Where fuses are of the type that can be operated as a disconnecting switch, a set of such fuses shall be permitted as the isolating switch.

**(C) Accessible to Qualified Persons Only.** The isolating switch shall be accessible to qualified persons only.

**(D) Connection to Ground.** Isolating switches shall be provided with a means for readily connecting the load side conductors to a grounding electrode system, equipment ground busbar, or grounded steel structure when disconnected from the source of supply.

A means for grounding the load side conductors to a grounding electrode system, equipment grounding busbar, or grounded structural steel shall not be required for any duplicate isolating switch installed and maintained by the electric supply company.

Exhibit 230.31 illustrates a two-position isolating switch that meets the requirement of 230.204(D). It grounds the load-side conductors when they are disconnected from high-voltage line buses.

**EXHIBIT 230.31** Two-position isolating switch for grounding load-side conductors disconnected from high-voltage line buses.

### 230.205 Disconnecting Means

**(A) Location.** The service disconnecting means shall be located in accordance with 230.70.

For either overhead or underground primary distribution systems on private property, the service disconnect shall be permitted to be located in a location that is not readily accessible, if the disconnecting means can be operated by mechanical linkage from a readily accessible point, or electronically in accordance with 230.205(C), where applicable.

As is the case for services operating at 600 volts nominal or less, the general requirement for service disconnecting means in systems rated over 600 volts is that it be readily accessible. Because this ready access may not be possible or desirable (from an employee safety perspective), the use of a readily accessible operating mechanism or of an electronic switching device are acceptable alternatives to having ready access to the actual switching device or mechanism.

**(B) Type.** Each service disconnect shall simultaneously disconnect all ungrounded service conductors that it controls and shall have a fault-closing rating that is not less than the maximum short-circuit current available at its supply terminals.

Where fused switches or separately mounted fuses are installed, the fuse characteristics shall be permitted to contribute to the fault-closing rating of the disconnecting means.

**(C) Remote Control.** For multibuilding, industrial installations under single management, the service disconnecting means shall be permitted to be located at a separate building or structure. In such cases, the service disconnecting means shall be permitted to be electrically operated by a readily accessible, remote-control device.

### 230.206 Overcurrent Devices as Disconnecting Means

Where the circuit breaker or alternative for it, as specified in 230.208 for service overcurrent devices, meets the requirements specified in 230.205, they shall constitute the service disconnecting means.

### 230.208 Protection Requirements

A short-circuit protective device shall be provided on the load side of, or as an integral part of, the service disconnect, and shall protect all ungrounded conductors that it supplies. The protective device shall be capable of detecting and interrupting all values of current, in excess of its trip setting or melting point, that can occur at its location. A fuse rated in continuous amperes not to exceed three times the ampacity of the conductor, or a circuit breaker with a trip setting of not more than six times the ampacity of the conductors, shall be considered as providing the required short-circuit protection.

Informational Note: See Table 310.60(C)(67) through Table 310.60(C)(86) for ampacities of conductors rated 2001 volts and above.

Overcurrent devices shall conform to 230.208(A) and (B).

**(A) Equipment Type.** Equipment used to protect service-entrance conductors shall meet the requirements of Article 490, Part II.

**(B) Enclosed Overcurrent Devices.** The restriction to 80 percent of the rating for an enclosed overcurrent device for continuous loads shall not apply to overcurrent devices installed in systems operating at over 600 volts.

### 230.209 Surge Arresters (Lightning Arresters)

Surge arresters installed in accordance with the requirements of Article 280 shall be permitted on each ungrounded overhead service conductor.

### 230.210 Service Equipment — General Provisions

Service equipment, including instrument transformers, shall conform to Article 490, Part I.

### 230.211 Metal-Enclosed Switchgear

Metal-enclosed switchgear shall consist of a substantial metal structure and a sheet metal enclosure. Where installed over a combustible floor, suitable protection thereto shall be provided.

Exhibit 230.32 is an example of a metal-enclosed switchgear assembly covered by 230.211. Metal-enclosed switchgear can be used in lieu of a vault in accordance with 230.212.

**EXHIBIT 230.32** Assembly of metal-enclosed switchgear. (Courtesy of Schneider Electric)

### 230.212 Over 35,000 Volts

Where the voltage exceeds 35,000 volts between conductors that enter a building, they shall terminate in a metal-enclosed switchgear compartment or a vault conforming to the requirements of 450.41 through 450.48.

## I. General

### 240.1 Scope

Parts I through VII of this article provide the general requirements for overcurrent protection and overcurrent protective devices not more than 600 volts, nominal. Part VIII covers overcurrent protection for those portions of supervised industrial installations operating at voltages of not more than 600 volts, nominal. Part IX covers overcurrent protection over 600 volts, nominal.

**Informational Note:** Overcurrent protection for conductors and equipment is provided to open the circuit if the current reaches a value that will cause an excessive or dangerous temperature in conductors or conductor insulation. See also 110.9 for requirements for interrupting ratings and 110.10 for requirements for protection against fault currents.

### 240.2 Definitions

**Current-Limiting Overcurrent Protective Device.** A device that, when interrupting currents in its current-limiting range, reduces the current flowing in the faulted circuit to a magnitude substantially less than that obtainable in the same circuit if the device were replaced with a solid conductor having comparable impedance.

A current-limiting protective device is one that cuts off a fault current in less than one-half cycle. It thus prevents short-circuit currents from building up to their full available values. Most electrical distribution systems can deliver high ground-fault or short-circuit currents to components such as conductors and service equipment. These components may not be able to handle short-circuit currents; they may be damaged or destroyed, and serious burn downs and fires could result. Properly selected current-limiting overcurrent

protective devices, such as the ones shown in Exhibit 240.1, limit the let-through energy to an amount that does not exceed the rating of the components, in spite of high available short-circuit currents.

Proper selection of current-limiting devices depends on the type of device selected. For example, a Class RK5 fuse is not as current limiting as a Class RK1 fuse. Furthermore, a Class RK1 fuse is not as current limiting as a high-speed semiconductor fuse. See 110.9 and 110.10 for details on interrupting ratings, circuit impedance, and other characteristics.

**EXHIBIT 240.1** Class R current-limiting fuses with rejection feature to prohibit the installation of non-current-limiting fuses. (Courtesy of Cooper Bussmann, a division of Cooper Industries, PLC)

**Supervised Industrial Installation.** For the purposes of Part VIII, the industrial portions of a facility where all of the following conditions are met:

- (1) Conditions of maintenance and engineering supervision ensure that only qualified persons monitor and service the system.
- (2) The premises wiring system has 2500 kVA or greater of load used in industrial process(es), manufacturing activities, or both, as calculated in accordance with Article 220.
- (3) The premises has at least one service or feeder that is more than 150 volts to ground and more than 300 volts phase-to-phase.

This definition excludes installations in buildings used by the industrial facility for offices, warehouses, garages, machine shops, and recreational facilities that are not an integral part of the industrial plant, substation, or control center.

One part of qualifying as an industrial establishment in accordance with this definition is that the facility has a combined process and manufacturing load greater than 2500 kVA. All process or manufacturing loads from each low-, medium-, and high-voltage system can be added together to satisfy the load requirements of Part VIII of Article 240. Loads not associated with manufacturing or processing cannot be used to meet the 2500-kVA minimum requirement. Loads are calculated in accordance with Article 220.

The requirements of Part VIII apply only to low-voltage electrical systems (600 volts, nominal, or less) used for process or manufacturing. Part VIII does not apply to electrical systems operating at over 600 volts, nominal, or to electrical systems that serve separate facilities, such as offices, warehouses, garages, machine shops, or recreational buildings, that are not a part of the manufacturing or industrial process. However, if a part of the industrial process or manufacturing electrical system is used to serve an office, warehouse, garage, machine shop, or recreational facility that is an integral part of the industrial plant, control center, or substation, Part VIII can still apply to the total process or manufacturing electrical system.

**Tap Conductors.** As used in this article, a tap conductor is defined as a conductor, other than a service conductor, that has overcurrent protection ahead of its point of supply that exceeds the value permitted for similar conductors that are protected as described elsewhere in 240.4.

Tap conductors are those branch circuit and feeder conductors subject to the special overcurrent protection requirements specified in 240.21. Overcurrent protection includes short-circuit, ground-fault, and overload protection, and the general requirement in 240.21 is for conductor overcurrent protection to be provided at the point a conductor is supplied. The provisions of 240.21 allow for the installation of branch circuit and feeder conductors that are protected against overcurrent using methods other than having short-circuit, ground-fault, and overload protection all provided by the overcurrent protective device on the line side of their point of supply.

### 240.3 Other Articles

Equipment shall be protected against overcurrent in accordance with the article in this *Code* that covers the type of equipment specified in Table 240.3.

### 240.4 Protection of Conductors

Conductors, other than flexible cords, flexible cables, and fixture wires, shall be protected against overcurrent in accordance with their ampacities specified in 310.15, unless otherwise permitted or required in 240.4(A) through (G).

**Informational Note:** See ICEA P-32-382-2007 for information on allowable short-circuit currents for insulated copper and aluminum conductors.

**(A) Power Loss Hazard.** Conductor overload protection shall not be required where the interruption of the circuit

would create a hazard, such as in a material-handling magnet circuit or fire pump circuit. Short-circuit protection shall be provided.

Informational Note: See NFPA 20-2010, *Standard for the Installation of Stationary Pumps for Fire Protection*.

**(B) Overcurrent Devices Rated 800 Amperes or Less.**

The next higher standard overcurrent device rating (above the ampacity of the conductors being protected) shall be permitted to be used, provided all of the following conditions are met:

- (1) The conductors being protected are not part of a branch circuit supplying more than one receptacle for cord-and-plug-connected portable loads.
- (2) The ampacity of the conductors does not correspond with the standard ampere rating of a fuse or a circuit breaker without overload trip adjustments above its rating (but that shall be permitted to have other trip or rating adjustments).
- (3) The next higher standard rating selected does not exceed 800 amperes.

Article 310 contains conductor ampacity tables based on conductor types, voltage rating, and conditions of use and application. For premises electrical installations operating at 600 volts and below, the most widely used ampacity table is Table 310.15(B)(16). Section 240.6 lists the standard ratings of overcurrent devices. Where the ampacity of the conductor specified in these tables does not match the rating of the standard overcurrent device, 240.4(B) permits the use of the next larger standard overcurrent device. All three conditions in 240.4(B) must be met for this permission to apply. However, if the ampacity of a conductor corresponds with a standard rating in 240.6, the conductor is to be protected by the standard rated device or by one with a smaller rating. For example, in Table 310.15(B)(16), 3 AWG, 75°C copper, Type THWN, the ampacity is listed as 100 amperes. That conductor would have to be protected by an overcurrent protective device rated not more than 100 amperes, unless otherwise permitted in 240.4(E), (F), or (G).

The provisions of 240.4(B) do not modify or change the allowable ampacity of the conductor — they only serve to provide a reasonable increase in the permitted overcurrent protective device rating where the allowable ampacity and the standard overcurrent protective device ratings do not correspond. For circuits rated 600 volts and under, the allowable ampacity of branch circuit, feeder, or service conductors always has to be capable of supplying the calculated load in accordance with the requirements of 210.19(A)(1), 215.2(A)(1), and 230.42(A). For example, a 500-kcmil THWN copper conductor has an allowable ampacity of 380 amperes from Table 310.15(B)(16). This conductor can supply a load

not exceeding 380 amperes and, in accordance with 240.4(B), can be protected by a 400-ampere overcurrent protective device.

Section 240.4(B) references 310.15; therefore all of the provisions of that section are applicable. Section 310.15(B)(7) permits the conductor types and sizes specified in Table 310.15(B)(7) to supply calculated loads based on the ratings specified in that table. The service and main power feeder loads permitted to be supplied by the conductor types and sizes covered in Table 310.15(B)(7) exceed the conductor ampacities for the same conductor types and sizes specified in Table 310.15(B)(16). The overcurrent protection for these residential supply conductors is also permitted to be based on the increased rating allowed by this Article 310 table. Application of 310.15(B)(7) and its table is permitted only for single-phase, 120/240-volt, residential services and main power feeders. The increased ratings given in Table 310.15(B)(7) are based on the significant diversity inherent to most dwelling unit loads and the fact that only the two ungrounded service or feeder conductors are considered to be current carrying.

**(C) Overcurrent Devices Rated over 800 Amperes.**

Where the overcurrent device is rated over 800 amperes, the ampacity of the conductors it protects shall be equal to or greater than the rating of the overcurrent device defined in 240.6.

**(D) Small Conductors.** Unless specifically permitted in 240.4(E) or (G), the overcurrent protection shall not exceed that required by (D)(1) through (D)(7) after any correction factors for ambient temperature and number of conductors have been applied.

**(1) 18 AWG Copper.** 7 amperes, provided all the following conditions are met:

- (1) Continuous loads do not exceed 5.6 amperes.
- (2) Overcurrent protection is provided by one of the following:
  - a. Branch-circuit-rated circuit breakers listed and marked for use with 18 AWG copper wire
  - b. Branch-circuit-rated fuses listed and marked for use with 18 AWG copper wire
  - c. Class CC, Class J, or Class T fuses

**(2) 16 AWG Copper.** 10 amperes, provided all the following conditions are met:

- (1) Continuous loads do not exceed 8 amperes.
- (2) Overcurrent protection is provided by one of the following:
  - a. Branch-circuit-rated circuit breakers listed and marked for use with 16 AWG copper wire

- b. Branch-circuit-rated fuses listed and marked for use with 16 AWG copper wire
- c. Class CC, Class J, or Class T fuses

**(3) 14 AWG Copper.** 15 amperes

**(4) 12 AWG Aluminum and Copper-Clad Aluminum.** 15 amperes

**(5) 12 AWG Copper.** 20 amperes

**(6) 10 AWG Aluminum and Copper-Clad Aluminum.** 25 amperes

**(7) 10 AWG Copper.** 30 amperes

**(E) Tap Conductors.** Tap conductors shall be permitted to be protected against overcurrent in accordance with the following:

- (1) 210.19(A)(3) and (A)(4), Household Ranges and Cooking Appliances and Other Loads
- (2) 240.5(B)(2), Fixture Wire
- (3) 240.21, Location in Circuit
- (4) 368.17(B), Reduction in Ampacity Size of Busway
- (5) 368.17(C), Feeder or Branch Circuits (busway taps)
- (6) 430.53(D), Single Motor Taps

**(F) Transformer Secondary Conductors.** Single-phase (other than 2-wire) and multiphase (other than delta-delta, 3-wire) transformer secondary conductors shall not be considered to be protected by the primary overcurrent protective device. Conductors supplied by the secondary side of a single-phase transformer having a 2-wire (single-voltage) secondary, or a three-phase, delta-delta connected transformer having a 3-wire (single-voltage) secondary, shall be permitted to be protected by overcurrent protection provided on the primary (supply) side of the transformer, provided this protection is in accordance with 450.3 and does not exceed the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio.

The fundamental requirement of 240.4 specifies that conductors are to be protected against overcurrent in accordance with their ampacity, and 240.21 requires that the protection be provided at the point the conductor receives its supply. Section 240.4(F) permits the secondary circuit conductors from a transformer to be protected by overcurrent devices in the primary circuit conductors of the transformer only in the following two special cases:

- 1. A transformer with a 2-wire primary and a 2-wire secondary, provided the transformer primary is protected in accordance with 450.3

- 2. A 3-phase, delta-delta-connected transformer having a 3-wire, single-voltage secondary, provided its primary is protected in accordance with 450.3

Except for those two special cases, transformer secondary conductors must be protected by the use of overcurrent devices, because the primary overcurrent devices do not provide such protection.

#### Application Example

A single-phase transformer with a 2-wire secondary is provided with primary overcurrent protection rated at 50 amperes. The transformer is rated 480/240 volts. Conductors supplied by the secondary have an ampacity of 100 amperes. Is the 50-ampere overcurrent protection allowed to protect the conductors that are connected to the secondary?

The secondary-to-primary voltage ratio in this example is:

$$240 \div 480 = 0.5$$

Multiply the secondary conductor ampacity by this ratio:

$$100 \text{ amperes} \times 0.5 = 50 \text{ amperes}$$

#### Solution

Therefore, the maximum rating of the overcurrent device allowed on the primary of the transformer that will also provide overcurrent protection for the secondary conductors is 50 amperes. These secondary conductors are not tap conductors, are not limited in length, and do not require overcurrent protection where they receive their supply, which is at the transformer secondary terminals.

However, if the secondary consisted of a 3-wire, 240/120-volt system, a 120-volt line-to-neutral load could draw up to 200 amperes before the overcurrent device in the primary actuated. That would be the result of the 1:4 secondary-to-primary voltage ratio of the 120-volt winding of the transformer secondary, which can cause dangerous overloading of the secondary conductors.

**(G) Overcurrent Protection for Specific Conductor Applications.** Overcurrent protection for the specific conductors shall be permitted to be provided as referenced in Table 240.4(G).

### 240.5 Protection of Flexible Cords, Flexible Cables, and Fixture Wires

Flexible cord and flexible cable, including tinsel cord and extension cords, and fixture wires shall be protected against overcurrent by either 240.5(A) or (B).

**(A) Ampacities.** Flexible cord and flexible cable shall be protected by an overcurrent device in accordance with their

**TABLE 240.4(G) Specific Conductor Applications**

Conductor	Article	Section
Air-conditioning and refrigeration equipment circuit conductors	440, Parts III, VI	
Capacitor circuit conductors	460	460.8(B) and 460.25(A)–(D)
Control and instrumentation circuit conductors (Type ITC)	727	727.9
Electric welder circuit conductors	630	630.12 and 630.32
Fire alarm system circuit conductors	760	760.43, 760.45, 760.121, and Chapter 9, Tables 12(A) and 12(B)
Motor-operated appliance circuit conductors	422, Part II	
Motor and motor-control circuit conductors	430, Parts III, IV, V, VI, VII	
Phase converter supply conductors	455	455.7
Remote-control, signaling, and power-limited circuit conductors	725	725.43, 725.45, 725.121, and Chapter 9, Tables 11(A) and 11(B)
Secondary tie conductors	450	450.6

ampacity as specified in Table 400.5(A)(1) and Table 400.5(A)(2). Fixture wire shall be protected against overcurrent in accordance with its ampacity as specified in Table 402.5. Supplementary overcurrent protection, as covered in 240.10, shall be permitted to be an acceptable means for providing this protection.

**(B) Branch-Circuit Overcurrent Device.** Flexible cord shall be protected, where supplied by a branch circuit, in accordance with one of the methods described in 240.5(B)(1), (B)(3), or (B)(4). Fixture wire shall be protected, where supplied by a branch circuit, in accordance with 240.5(B)(2).

**(1) Supply Cord of Listed Appliance or Luminaire.** Where flexible cord or tinsel cord is approved for and used with a specific listed appliance or luminaire, it shall be considered to be protected when applied within the appliance or luminaire listing requirements. For the purposes of this section, a luminaire may be either portable or permanent.

**(2) Fixture Wire.** Fixture wire shall be permitted to be tapped to the branch-circuit conductor of a branch circuit in accordance with the following:

- (1) 20-ampere circuits — 18 AWG, up to 15 m (50 ft) of run length

- (2) 20-ampere circuits — 16 AWG, up to 30 m (100 ft) of run length
- (3) 20-ampere circuits — 14 AWG and larger
- (4) 30-ampere circuits — 14 AWG and larger

Sections 240.5(B)(1) through (B)(4) permit smaller conductors to be connected to branch circuits of a greater rating. For flexible cords, 240.5(B)(1) and (B)(3) specify that flexible cord connected to a listed appliance or portable lamp or used in a listed extension cord set is considered to be protected as long as the appliance, lamp, or extension cord is used in accordance with its listing requirements. These listing requirements are developed by the third-party testing and listing organizations with technical input from cord, appliance, and lamp manufacturers. For fixture wire, 240.5(B)(2) establishes a maximum protective device rating based on a minimum conductor size and a maximum conductor length.

- (5) 40-ampere circuits — 12 AWG and larger
- (6) 50-ampere circuits — 12 AWG and larger

**(3) Extension Cord Sets.** Flexible cord used in listed extension cord sets shall be considered to be protected when applied within the extension cord listing requirements.

**(4) Field Assembled Extension Cord Sets.** Flexible cord used in extension cords made with separately listed and installed components shall be permitted to be supplied by a branch circuit in accordance with the following:

- 20-ampere circuits — 16 AWG and larger

Field-assembled extension cords are permitted by 240.5(B)(4), provided the conductors are 16 AWG or larger and the overcurrent protection for the branch circuit to which the cord is connected does not exceed 20 amperes. If a field-assembled extension cord is connected to a circuit rated higher than 20 amperes, the cord ampacity cannot be less than the rating of the circuit overcurrent protective device. The cord and the cord caps and connectors used for this type of assembly are required to be listed.

## 240.6 Standard Ampere Ratings

**(A) Fuses and Fixed-Trip Circuit Breakers.** The standard ampere ratings for fuses and inverse time circuit breakers shall be considered 15, 20, 25, 30, 35, 40, 45, 50, 60, 70, 80, 90, 100, 110, 125, 150, 175, 200, 225, 250, 300, 350, 400, 450, 500, 600, 700, 800, 1000, 1200, 1600, 2000, 2500, 3000, 4000, 5000, and 6000 amperes. Additional standard ampere ratings for fuses shall be 1, 3, 6, 10, and 601. The use of fuses and inverse time circuit breakers with nonstandard ampere ratings shall be permitted.

Manufacturers of both fuses and inverse-time circuit breakers have, or can make available, products with ampere ratings other than those listed in 240.6(A). Selection of such nonstandard ratings is not required by the *Code* but may permit better protection for conductors.

**(B) Adjustable-Trip Circuit Breakers.** The rating of adjustable-trip circuit breakers having external means for adjusting the current setting (long-time pickup setting), not meeting the requirements of 240.6(C), shall be the maximum setting possible.

**(C) Restricted Access Adjustable-Trip Circuit Breakers.** A circuit breaker(s) that has restricted access to the adjusting means shall be permitted to have an ampere rating(s) that is equal to the adjusted current setting (long-time pickup setting). Restricted access shall be defined as located behind one of the following:

- (1) Removable and sealable covers over the adjusting means
- (2) Bolted equipment enclosure doors
- (3) Locked doors accessible only to qualified personnel

The set long-time pickup rating (as opposed to the instantaneous trip rating) of an adjustable-trip circuit breaker covered in 240.6(C)(3) is permitted to be considered the circuit breaker rating where access to the adjustment means is limited. This access limitation can be provided by locating the adjustment means behind sealable covers, as shown in Exhibit 240.2, behind bolted equipment enclosures, or behind locked equipment room doors with access available only to qualified personnel. The purpose of limiting access to the adjustment prevents tampering or readjustment by unqualified personnel.

### 240.8 Fuses or Circuit Breakers in Parallel

Fuses and circuit breakers shall be permitted to be connected in parallel where they are factory assembled in parallel and listed as a unit. Individual fuses, circuit breakers, or combinations thereof shall not otherwise be connected in parallel.

Section 240.8 prohibits the use of fuses or circuit breakers in parallel unless they are factory assembled in parallel and listed as a unit. Section 404.17 prohibits the use of fuses in parallel in fused switches except as permitted by 240.8 for listed assemblies.

It is not the intent of 240.8 to restore the use of standard fuses in parallel in disconnect switches. However, 240.8 recognizes parallel low-voltage circuit breakers or fuses and

**EXHIBIT 240.2** An adjustable-trip circuit breaker with a transparent, removable, and sealable cover. (Courtesy of Schneider Electric)

parallel high-voltage circuit breakers or fuses if they are tested and factory assembled in parallel and listed as a unit.

High-voltage fuses have long been used in parallel when they are assembled in an identified common mounting.

### 240.9 Thermal Devices

Thermal relays and other devices not designed to open short circuits or ground faults shall not be used for the protection of conductors against overcurrent due to short circuits or ground faults, but the use of such devices shall be permitted to protect motor branch-circuit conductors from overload if protected in accordance with 430.40.

### 240.10 Supplementary Overcurrent Protection

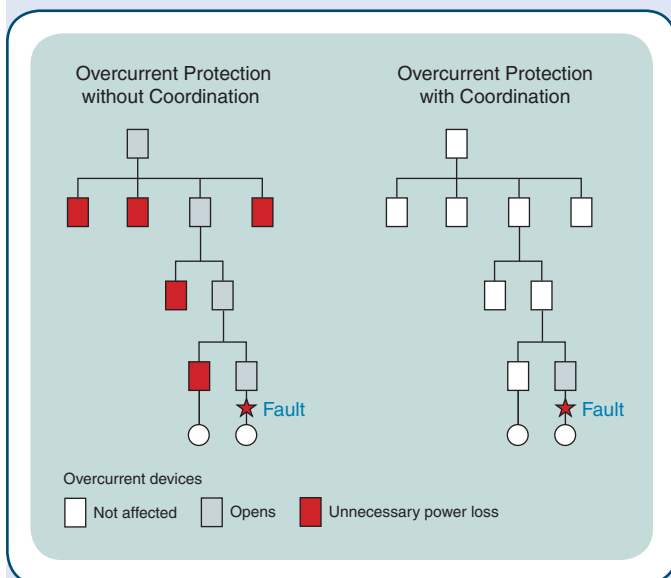

Where supplementary overcurrent protection is used for luminaires, appliances, and other equipment or for internal circuits and components of equipment, it shall not be used as a substitute for required branch-circuit overcurrent devices or in place of the required branch-circuit protection. Supplementary overcurrent devices shall not be required to be readily accessible.

### 240.12 Electrical System Coordination

Where an orderly shutdown is required to minimize the hazard(s) to personnel and equipment, a system of coordination based on the following two conditions shall be permitted:

- (1) Coordinated short-circuit protection

With coordinated overcurrent protection, as permitted by 240.12, the faulted or overloaded circuit is isolated by the selective operation of only the overcurrent protective device closest to the overcurrent condition. This selective operation prevents power loss to unaffected loads. Under this provision coordinated short-circuit protection is required to automatically open the circuit by localizing and de-energizing the faulted portion of the circuit, but an overload condition is not required to result in automatic opening of a protective device. Instead, an alarm can be used to warn of the overload condition and remedial action can be taken. In some circumstances, an orderly shutdown of a system or process is more critical to personnel and equipment safety than is the automatic operation of the overcurrent protective device in response to an overload. Selective coordination requirements for specific systems or equipment are contained in 620.62, 695.3(C)(3), 700.27, 701.27, and 708.54. Examples of overcurrent protection with and without coordinated protection are illustrated in Exhibit 240.3. The system with coordinated overcurrent protection (short-circuit in this case) localizes the fault and only the overcurrent protective device closest to the faulted portion of the circuit opens.

**EXHIBIT 240.3** Overcurrent protection schemes without system coordination and with system coordination.

- (2) Overload indication based on monitoring systems or devices

**Informational Note:** The monitoring system may cause the condition to go to alarm, allowing corrective action or an orderly shutdown, thereby minimizing personnel hazard and equipment damage.

### 240.13 Ground-Fault Protection of Equipment

Ground-fault protection of equipment shall be provided in accordance with the provisions of 230.95 for solidly grounded wye electrical systems of more than 150 volts to ground but not exceeding 600 volts phase-to-phase for each individual device used as a building or structure main disconnecting means rated 1000 amperes or more.

The provisions of this section shall not apply to the disconnecting means for the following:

- (1) Continuous industrial processes where a nonorderly shutdown will introduce additional or increased hazards
- (2) Installations where ground-fault protection is provided by other requirements for services or feeders
- (3) Fire pumps

Section 240.13 extends the requirement of 230.95 to building disconnects, regardless of how the disconnects are classified (service disconnects or building disconnects for feeders or even branch circuits). See 215.10 and Article 225, Part II, for the requirements for building disconnects not on the utility service.

Section 240.13 requires each building or structure disconnect that is rated 1000 amperes or more, on a solidly grounded system of more than 150 volts to ground (e.g., a 480Y/277-volt system), to be provided with ground-fault protection for equipment. Provisions are included for fire pumps and for continuous industrial processes in which non-orderly shutdowns would introduce additional hazards.

Where ground-fault protection for equipment is installed at the service equipment and feeders or branch circuits are installed from that service to supply other buildings or structures, the disconnecting means at any subsequent building is not required to be provided with ground-fault protection if the service device provides the required protection. Installations performed prior to the 2008 *Code* permitted “re-grounding” of the grounded conductor at the separate building if an equipment grounding conductor was not included with the supply circuit. Where re-grounding of the neutral occurs downstream from the service, the re-grounding may nullify or result in unwanted operation of the ground-fault protection because the neutral current has parallel paths on which to return to the source. Feeders or branch circuits supplying other buildings or structures may have to be isolated to allow for proper operation of the service ground-fault protection, and separate ground-fault protection installed at the building disconnecting means is then necessary to meet the provisions of 240.13.

### 240.15 Ungrounded Conductors

**(A) Overcurrent Device Required.** A fuse or an overcurrent trip unit of a circuit breaker shall be connected in series with each ungrounded conductor. A combination of a current

transformer and overcurrent relay shall be considered equivalent to an overcurrent trip unit.

Informational Note: For motor circuits, see Parts III, IV, V, and XI of Article 430.

**(B) Circuit Breaker as Overcurrent Device.** Circuit breakers shall open all ungrounded conductors of the circuit both manually and automatically unless otherwise permitted in 240.15(B)(1), (B)(2), (B)(3), and (B)(4).

**(1) Multiwire Branch Circuits.** Individual single-pole circuit breakers, with identified handle ties, shall be permitted as the protection for each ungrounded conductor of multiwire branch circuits that serve only single-phase line-to-neutral loads.

**(2) Grounded Single-Phase Alternating-Current Circuits.** In grounded systems, individual single-pole circuit breakers rated 120/240 volts ac, with identified handle ties, shall be permitted as the protection for each ungrounded conductor for line-to-line connected loads for single-phase circuits.

**(3) 3-Phase and 2-Phase Systems.** For line-to-line loads in 4-wire, 3-phase systems or 5-wire, 2-phase systems, individual single-pole circuit breakers rated 120/240 volts ac with identified handle ties shall be permitted as the protection for each ungrounded conductor, if the systems have a grounded neutral point and the voltage to ground does not exceed 120 volts.

**(4) 3-Wire Direct-Current Circuits.** Individual single-pole circuit breakers rated 125/250 volts dc with identified handle ties shall be permitted as the protection for each ungrounded conductor for line-to-line connected loads for 3-wire, direct-current circuits supplied from a system with a grounded neutral where the voltage to ground does not exceed 125 volts.

Multiwire branch circuits are permitted to supply line-to-line connected loads where the loads are associated with a single piece of utilization equipment or where all of the ungrounded conductors are opened simultaneously by the branch-circuit overcurrent device (automatic opening in response to overcurrent). See the commentary following 210.4(C) for additional information.

The basic rule in 240.15 requires circuit breakers to open all ungrounded conductors of the circuit when they trip (automatic operation in response to overcurrent) or are manually operated as a disconnecting means. For 2-wire circuits with one conductor grounded, this rule is simple and needs no further explanation.

Two or more individual single-pole circuit breakers with their handles joined together using an identified handle

tie can be used as the protection of line-to-line connected loads in single-phase and 3-phase alternating current systems, but this provision is limited to circuit breakers rated 120/240 volts. For multiwire branch circuits of 600 volts or less, however, there are two acceptable methods of complying with this rule.

The first, and most widely used, method is to install a multipole circuit breaker with an internal common trip mechanism. The use of such multipole devices ensures compliance with all of the *Code* requirements for overcurrent protection and disconnecting of multiwire branch circuits. This breaker is operated by an external single lever internally attached to the two or three poles of the circuit breaker, or the external lever may be attached to multiple handles operated as one, provided the breaker is a factory-assembled unit in accordance with 240.8. Underwriters Laboratories refers to these devices as *multipole common trip circuit breakers*. This type of circuit breaker is required to be used for branch circuits that comprise multiple ungrounded conductors supplied by ungrounded 3-phase and single-phase systems. Where circuit breakers are used on ungrounded systems, it is important to verify compliance with the application requirements in 240.85. Of course, multipole common trip circuit breakers are permitted to be installed on any branch circuit supplied from a grounded system where used within their ratings.

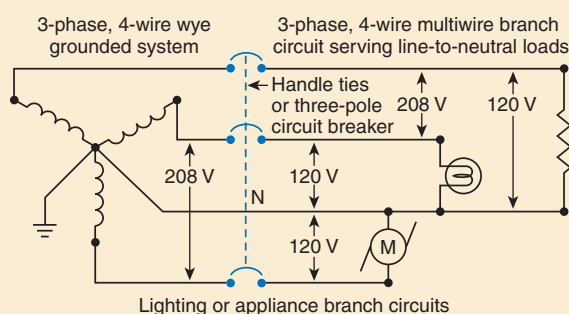

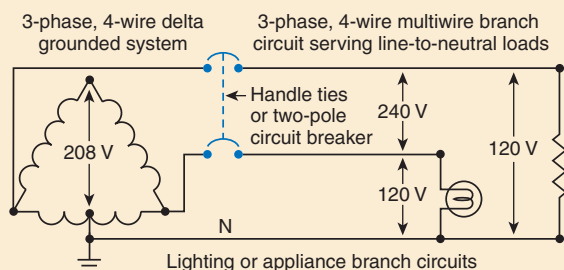

The second option permitted for multiwire branch circuits is to use two or three single-pole circuit breakers and add an identified handle tie to function as a common operating handle. This multipole circuit breaker is field assembled by externally attaching an identified common lever (handle tie) onto the two or three individual circuit breakers. It is important to understand that handle ties do not cause the circuit breaker to function as a common trip device; rather, they only allow common operation as a disconnecting means. Handle tie mechanism circuit breakers are permitted as a substitute for internal common trip mechanism circuit breakers only for limited applications. Unless specifically prohibited elsewhere, circuit breakers with identified handle ties are permitted for multiwire branch circuits only where the circuit is supplied from grounded 3-phase or grounded single-phase systems. The single-pole circuit breakers used together in this fashion must be rated for the dual voltage encountered, such as 120/240 volts. The term *identified* requires the use of hardware designed specifically to perform this common disconnecting means function. The use of homemade hardware such as nails or pieces of wire to perform this function is not an *identified* means.

The requirements of 240.15 have to be correlated with the requirements in 210.4(B) covering disconnection of multiwire branch circuits. Section 210.4(B) requires a means to simultaneously disconnect all ungrounded conductors of the multiwire branch circuit. The use of a multipole switch or

circuit breaker satisfies the 210.4(B) requirement, as does the use of single-pole circuit breakers with identified handle ties. The use of a multipole circuit breaker or single-pole

**EXHIBIT 240.4** Examples of circuits that require multipole common trip-type circuit breakers, in accordance with 240.15(B).

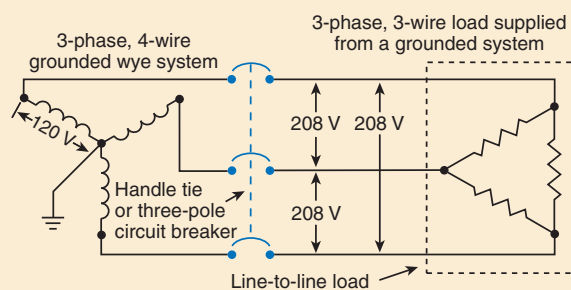

**EXHIBIT 240.5** Examples of circuits in which single-pole circuit breakers are permitted, in accordance with 240.15(B)(1), because they open the ungrounded conductor of the circuit.

circuit breakers joined with handle ties to comply with 210.4(B) also satisfies the requirements of 240.15 on the use of circuit breakers to provide overcurrent protection of multiwire branch circuits.

Section 240.15(B)(4) covers protection of direct current circuits and permits the use of two single-pole circuit breakers (rated for dc application) with identified handle ties to be used for the overcurrent protection of line-to-line connected loads. The three-wire circuits covered by this provision are *multiwire branch circuits* per the definition of that term in Article 100, and as such are subject to all of the requirements specified in 210.4.

Exhibits 240.4 through 240.6 illustrate the application of 240.15(B). In Exhibit 240.4, where multipole common

**EXHIBIT 240.6** Examples of circuits in which identified handle ties are permitted to provide the simultaneous disconnecting function in accordance with 240.15(B)(2) or 240.15(B)(3).

trip circuit breakers are required, handle ties are not permitted because the circuits are supplied from ungrounded systems. In Exhibit 240.5, where the supply systems are grounded, single-pole circuit breakers are permitted and handle ties or common trip operation is not required because the circuits supply line-to-neutral loads. In Exhibit 240.6, in which line-to-line loads are supplied from single-phase or 4-wire, 3-phase systems, identified handle ties or multipole common trip circuit breakers are permitted. The multiwire branch circuit shown in the top and middle diagrams supplies a single utilization equipment in accordance with 210.4(C), Exception No. 1.

## II. Location

### 240.21 Location in Circuit

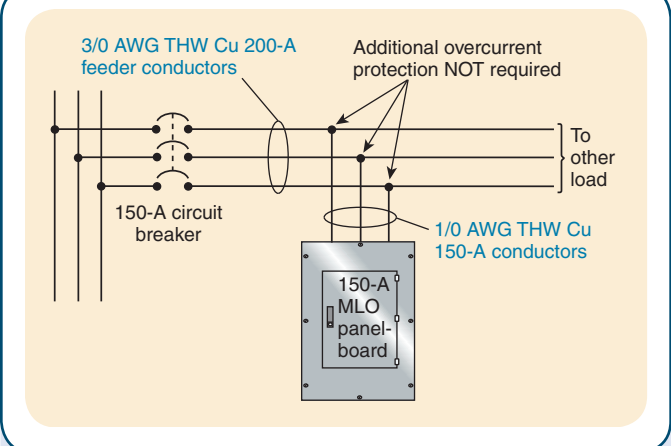

Overcurrent protection shall be provided in each ungrounded circuit conductor and shall be located at the point where the conductors receive their supply except as specified in 240.21(A) through (H). Conductors supplied under the provisions of 240.21(A) through (H) shall not supply another conductor except through an overcurrent protective device meeting the requirements of 240.4.

**(A) Branch-Circuit Conductors.** Branch-circuit tap conductors meeting the requirements specified in 210.19 shall be permitted to have overcurrent protection as specified in 210.20.

**(B) Feeder Taps.** Conductors shall be permitted to be tapped, without overcurrent protection at the tap, to a feeder as specified in 240.21(B)(1) through (B)(5). The provisions of 240.4(B) shall not be permitted for tap conductors.

The last sentence in 240.21(B) provides clear direction on the ampacity of tap conductors. The use of the next higher standard size provision of 240.4(B) is not permitted for feeder tap conductor applications. For instance, the use of a 500-kcmil THWN copper conductor [380 amperes, per Table 310.15(B)(16)] as a tap conductor to supply a 400-ampere rated device is not permitted, nor is it permitted to use the provision in 240.6 to establish the relationship between the size of the tap conductor and the rating or setting of the feeder overcurrent protective device. If the feeder overcurrent protective device is 1200 amperes, a conductor with an ampacity of 400 amperes is required.

Exhibit 240.7 illustrates a 1/0 AWG, Type THW copper conductor [150 amperes, from Table 310.15(B)(16)] connected to a 3/0 AWG, Type THW copper feeder conductor

**EXHIBIT 240.7** An example in which the sets of 1/0 AWG and the 3/0 AWG conductors are both protected by the 150 ampere circuit breaker. Conductors protected at or below their ampacity are not tap conductors and meet the general requirements of 240.4 and 240.21.

with an ampacity of 200 amperes (increased in size to compensate for voltage drop) that is protected by a 150-ampere overcurrent protective device. Because the ampacity of the 1/0 AWG conductor is not exceeded by the rating of the overcurrent device, the 1/0 AWG conductor is not considered to be a tap conductor based on the definition of *tap conductors* in 240.2. The overcurrent device protects both sets of conductors in accordance with the basic rule of 240.4, and additional overcurrent protection is not required at the point where the 1/0 AWG conductor is supplied, nor at the point where it terminates. Both the 1/0 AWG and the 3/0 AWG conductors are protected by the 150-ampere circuit breaker. In this application, the 1/0 AWG conductors are not tap conductors as defined in 240.2.

**(1) Taps Not over 3 m (10 ft) Long.** If the length of the tap conductors does not exceed 3 m (10 ft) and the tap conductors comply with all of the following:

- (1) The ampacity of the tap conductors is
  - a. Not less than the combined calculated loads on the circuits supplied by the tap conductors, and
  - b. Not less than the rating of the device supplied by the tap conductors or not less than the rating of the overcurrent protective device at the termination of the tap conductors.
- (2) The tap conductors do not extend beyond the switchboard, panelboard, disconnecting means, or control devices they supply.
- (3) Except at the point of connection to the feeder, the tap conductors are enclosed in a raceway, which shall ex-

tend from the tap to the enclosure of an enclosed switchboard, panelboard, or control devices, or to the back of an open switchboard.

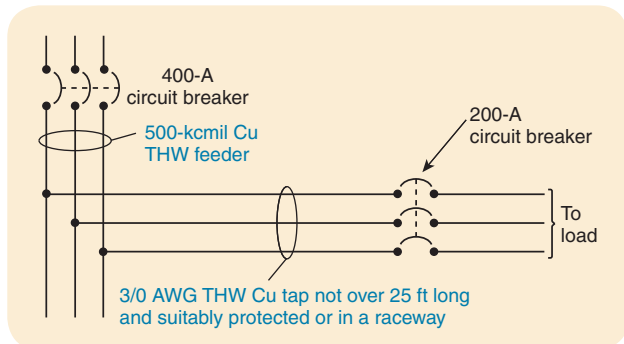

- (4) For field installations, if the tap conductors leave the enclosure or vault in which the tap is made, the ampacity of the tap conductors is not less than one-tenth of the rating of the overcurrent device protecting the feeder conductors.

Informational Note: For overcurrent protection requirements for panelboards, see 408.36.

**(2) Taps Not over 7.5 m (25 ft) Long.** Where the length of the tap conductors does not exceed 7.5 m (25 ft) and the tap conductors comply with all the following:

- (1) The ampacity of the tap conductors is not less than one-third of the rating of the overcurrent device protecting the feeder conductors.
- (2) The tap conductors terminate in a single circuit breaker or a single set of fuses that limit the load to the ampacity of the tap conductors. This device shall be permitted to supply any number of additional overcurrent devices on its load side.
- (3) The tap conductors are protected from physical damage by being enclosed in an approved raceway or by other approved means.

Exhibit 240.8 illustrates the feeder tap provision of 240.21(B)(2). In this example, three 3/0 AWG, Type THW copper tap conductors are protected from physical damage by being installed in a raceway. The tap conductors are not more than 25 ft in length between terminations, and the conductors are tapped from 500-kcmil, Type THW copper feeders and terminate in a single circuit breaker with a rating not greater than the ampacity of the tap conductors. The ampacity of the 3/0 AWG, Type THW copper conduc-

**EXHIBIT 240.8** An example in which the feeder taps terminate in a single circuit breaker, per 240.21(B)(2)(2).

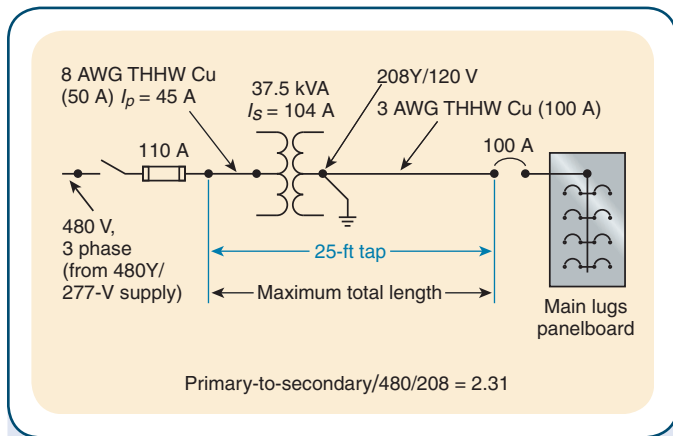

tor (200 amperes) is more than one-third the rating of the overcurrent device (400 amperes) protecting the feeder circuit. See Table 310.15(B)(16) for the ampacity of copper conductors in conduit. Note that the lengths specified in 240.21(B) and (C) apply to the conductors, not to a raceway enclosing the conductors or to the distance between the enclosures in which the tap conductors originate and terminate.

**(3) Taps Supplying a Transformer [Primary Plus Secondary Not over 7.5 m (25 ft) Long].** Where the tap conductors supply a transformer and comply with all the following conditions:

- (1) The conductors supplying the primary of a transformer have an ampacity at least one-third the rating of the overcurrent device protecting the feeder conductors.
- (2) The conductors supplied by the secondary of the transformer shall have an ampacity that is not less than the value of the primary-to-secondary voltage ratio multiplied by one-third of the rating of the overcurrent device protecting the feeder conductors.
- (3) The total length of one primary plus one secondary conductor, excluding any portion of the primary conductor that is protected at its ampacity, is not over 7.5 m (25 ft).
- (4) The primary and secondary conductors are protected from physical damage by being enclosed in an approved raceway or by other approved means.
- (5) The secondary conductors terminate in a single circuit breaker or set of fuses that limit the load current to not more than the conductor ampacity that is permitted by 310.15.

The provisions of 240.21(B)(3) cover applications where the conductor length of 25 ft is applied to the primary and secondary conductors (using the length of one primary conductor plus the length of one secondary conductor for the measurement). The primary conductors are tapped to a feeder, and the secondary conductors are required to terminate in a single overcurrent protective device. Where the primary conductors are protected in accordance with their ampacity, the provisions of 240.21(C)(6) permit the entire 25 ft measurement to be applied to the transformer secondary conductors. Exhibit 240.9 illustrates the conditions of 240.21(B)(3)(1) through (5). The overcurrent protection requirements of 408.36 for panelboards and 450.3(B) for transformers also apply.

**(4) Taps over 7.5 m (25 ft) Long.** Where the feeder is in a high bay manufacturing building over 11 m (35 ft) high at

**EXHIBIT 240.9** An example in which the transformer feeder taps (primary plus secondary) are not over 25 ft long, per 240.21(B)(3) and (C)(5).

walls and the installation complies with all the following conditions:

- (1) Conditions of maintenance and supervision ensure that only qualified persons service the systems.
- (2) The tap conductors are not over 7.5 m (25 ft) long horizontally and not over 30 m (100 ft) total length.
- (3) The ampacity of the tap conductors is not less than one-third the rating of the overcurrent device protecting the feeder conductors.
- (4) The tap conductors terminate at a single circuit breaker or a single set of fuses that limit the load to the ampacity of the tap conductors. This single overcurrent device shall be permitted to supply any number of additional overcurrent devices on its load side.
- (5) The tap conductors are protected from physical damage by being enclosed in an approved raceway or by other approved means.
- (6) The tap conductors are continuous from end-to-end and contain no splices.
- (7) The tap conductors are sized 6 AWG copper or 4 AWG aluminum or larger.
- (8) The tap conductors do not penetrate walls, floors, or ceilings.
- (9) The tap is made no less than 9 m (30 ft) from the floor.

Exhibit 240.10 illustrates the requirements of 240.21(B)(4). It permits a tap of 100 ft for manufacturing buildings with walls that are over 35 ft high where the tap connection is made not less than 30 ft from the floor and conditions of maintenance and supervision ensure that only qualified persons service these systems.

**(5) Outside Taps of Unlimited Length.** Where the conductors are located outdoors of a building or structure, ex-

**EXHIBIT 240.10** Application of 240.21(B)(4) in which the horizontal length of the feeder tap conductors does not exceed 25 ft, the total vertical plus horizontal length of the tap conductors does not exceed 100 ft, and the tap connection is made at a point not less than 30 ft from the floor.

cept at the point of load termination, and comply with all of the following conditions:

- (1) The conductors are protected from physical damage in an approved manner.
- (2) The conductors terminate at a single circuit breaker or a single set of fuses that limit the load to the ampacity of the conductors. This single overcurrent device shall be permitted to supply any number of additional overcurrent devices on its load side.
- (3) The overcurrent device for the conductors is an integral part of a disconnecting means or shall be located immediately adjacent thereto.
- (4) The disconnecting means for the conductors is installed at a readily accessible location complying with one of the following:
  - a. Outside of a building or structure
  - b. Inside, nearest the point of entrance of the conductors
  - c. Where installed in accordance with 230.6, nearest the point of entrance of the conductors

Section 240.21(B)(5) is a tap conductor provision that is similar in some respects to an installation of service conductors. The conductors are supplied from a feeder at an outdoor location and run to a building or structure without

limitations on the tap conductor length. The tap conductors must be protected against physical damage and must terminate in a single, fused disconnect or a single circuit breaker with a rating that does not exceed the ampacity of the tap conductors. This overcurrent protective device provides overload protection for the tap conductors. The fused switch or circuit breaker is installed at a readily accessible location either inside or outside a building or structure and is subject to the applicable requirements covering feeder disconnecting means in Part II of Article 225. The fused switch or circuit breaker is required to be installed inside or outside of the building or structure at a point nearest to where the tap conductors enter the building or structure.

**(C) Transformer Secondary Conductors.** A set of conductors feeding a single load, or each set of conductors feeding separate loads, shall be permitted to be connected to a transformer secondary, without overcurrent protection at the secondary, as specified in 240.21(C)(1) through (C)(6). The provisions of 240.4(B) shall not be permitted for transformer secondary conductors.

Informational Note: For overcurrent protection requirements for transformers, see 450.3.

The six applications covered in 240.21(C)(1) through (6) permit transformer secondary conductors without an overcurrent protective device at the point the secondary conductors receive their supply under one of the following conditions:

1. The primary overcurrent protective device, as described in 240.21(C)(1), can protect single-phase (2-wire) and 3-phase (delta-delta) transformer secondary conductors.
2. The transformer secondary conductors do not exceed 10 ft.
3. The transformer secondary conductors do not exceed 25 ft (two applications).
4. The transformer primary plus the secondary conductors do not exceed 25 ft.
5. The transformer secondary conductors are located outdoors.

Like 240.21(B) for conductors tapped to a feeder, 240.21(C) specifically prohibits application of 240.4(B) with transformer secondary conductors covered by the requirements of 240.21(C)(1) through (C)(6). See the commentary for 240.21(B).

The secondary terminals of a transformer are permitted to supply one or more than one set of secondary conductors. The first sentence of 240.21(C) specifies that the requirements apply to “a set of conductors supplying a single load”

or “to each set of conductors feeding separate loads.” For example, the secondary terminals could supply two separate sets of secondary conductors that feed two panelboards. One set of conductors could be installed using the 25-ft secondary conductor rule of 240.21(C)(6) while the other set of conductors could be installed using the 10-ft secondary conductor rule of 240.21(C)(2). Each set is treated individually in applying the applicable secondary conductor requirement. It is necessary to coordinate the secondary conductor protection requirements of 240.21(C) and, where applicable, the transformer secondary protection requirements in 450.3(A) and (B).

**(1) Protection by Primary Overcurrent Device.** Conductors supplied by the secondary side of a single-phase transformer having a 2-wire (single-voltage) secondary, or a three-phase, delta-delta connected transformer having a 3-wire (single-voltage) secondary, shall be permitted to be protected by overcurrent protection provided on the primary (supply) side of the transformer, provided this protection is in accordance with 450.3 and does not exceed the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio.

Single-phase (other than 2-wire) and multiphase (other than delta-delta, 3-wire) transformer secondary conductors are not considered to be protected by the primary overcurrent protective device.

**(2) Transformer Secondary Conductors Not over 3 m (10 ft) Long.** If the length of secondary conductor does not exceed 3 m (10 ft) and complies with all of the following:

- (1) The ampacity of the secondary conductors is
  - a. Not less than the combined calculated loads on the circuits supplied by the secondary conductors, and
  - b. Not less than the rating of the device supplied by the secondary conductors or not less than the rating of the overcurrent-protective device at the termination of the secondary conductors
- (2) The secondary conductors do not extend beyond the switchboard, panelboard, disconnecting means, or control devices they supply.
- (3) The secondary conductors are enclosed in a raceway, which shall extend from the transformer to the enclosure of an enclosed switchboard, panelboard, or control devices or to the back of an open switchboard.
- (4) For field installations where the secondary conductors leave the enclosure or vault in which the supply connection is made, the rating of the overcurrent device protecting the primary of the transformer, multiplied by the primary to secondary transformer voltage ratio, shall not exceed 10 times the ampacity of the secondary conductor.

Informational Note: For overcurrent protection requirements for panelboards, see 408.36.

The minimum size requirement in 240.21(C)(2) for 10-ft transformer secondary conductors establishes a relationship between the size of the ungrounded secondary conductors and the rating of the transformer primary overcurrent protective device similar to the sizing provisions applied in 240.21(B)(1) for 10-ft feeder tap conductors. This size-rating relationship is necessary because the transformer primary device also provides short-circuit ground-fault protection for the transformer secondary conductors. It is necessary to also ensure that the ampacity of the conductors is adequate for the calculated load and is not less than the rating of the device or overcurrent protective device in which the conductors terminate. The following example illustrates the application of this requirement.

#### Calculation Example

Apply the 25 ft secondary conductor protection provisions of 240.21(C)(6) to a transformer rated 75 kVA, 3-phase, 480-volt primary to 208Y/120-volt secondary. The transformer primary overcurrent protective device is rated 125 amperes. Determine the minimum secondary conductor size for this installation.

#### Solution

STEP 1. Determine 1/10 of the primary OCPD rating using the following calculation:

$$125 \text{ A} \div 10 = 12.5 \text{ A}$$

STEP 2. Determine the line-to-line primary to secondary voltage ratio:

$$\left(\frac{480}{208}\right) = 2.31$$

STEP 3. Minimum ampacity for ungrounded transformer secondary conductor:

$$12.5 \text{ A} \times 2.31 = 29 \text{ A} \rightarrow 10 \text{ AWG copper THWN [Table 310.15(B)(16)]: 30 A from 60°C column}$$

A 10 AWG copper conductor is permitted to be tapped from the secondary of this transformer with primary overcurrent protection rated 125 amperes. The load supplied by this secondary conductor cannot exceed the conductor's allowable ampacity from Table 310.15(B)(16) coordinated with the temperature rating of the conductor terminations in accordance with 110.14(C)(1)(a).

**(3) Industrial Installation Secondary Conductors Not over 7.5 m (25 ft) Long.** For industrial installations only, where the length of the secondary conductors does not exceed 7.5 m (25 ft) and complies with all of the following:

- (1) Conditions of maintenance and supervision ensure that only qualified persons service the systems.

- (2) The ampacity of the secondary conductors is not less than the secondary current rating of the transformer, and the sum of the ratings of the overcurrent devices does not exceed the ampacity of the secondary conductors.
- (3) All overcurrent devices are grouped.
- (4) The secondary conductors are protected from physical damage by being enclosed in an approved raceway or by other approved means.

**(4) Outside Secondary Conductors.** Where the conductors are located outdoors of a building or structure, except at the point of load termination, and comply with all of the following conditions:

- (1) The conductors are protected from physical damage in an approved manner.
- (2) The conductors terminate at a single circuit breaker or a single set of fuses that limit the load to the ampacity of the conductors. This single overcurrent device shall be permitted to supply any number of additional overcurrent devices on its load side.
- (3) The overcurrent device for the conductors is an integral part of a disconnecting means or shall be located immediately adjacent thereto.
- (4) The disconnecting means for the conductors is installed at a readily accessible location complying with one of the following:
  - a. Outside of a building or structure
  - b. Inside, nearest the point of entrance of the conductors
  - c. Where installed in accordance with 230.6, nearest the point of entrance of the conductors

**(5) Secondary Conductors from a Feeder Tapped Transformer.** Transformer secondary conductors installed in accordance with 240.21(B)(3) shall be permitted to have overcurrent protection as specified in that section.

**(6) Secondary Conductors Not over 7.5 m (25 ft) Long.** Where the length of secondary conductor does not exceed 7.5 m (25 ft) and complies with all of the following:

- (1) The secondary conductors shall have an ampacity that is not less than the value of the primary-to-secondary voltage ratio multiplied by one-third of the rating of the overcurrent device protecting the primary of the transformer.
- (2) The secondary conductors terminate in a single circuit breaker or set of fuses that limit the load current to not more than the conductor ampacity that is permitted by 310.15.
- (3) The secondary conductors are protected from physical damage by being enclosed in an approved raceway or by other approved means.

**(D) Service Conductors.** Service conductors shall be permitted to be protected by overcurrent devices in accordance with 230.91.

**(E) Busway Taps.** Busways and busway taps shall be permitted to be protected against overcurrent in accordance with 368.17.

**(F) Motor Circuit Taps.** Motor-feeder and branch-circuit conductors shall be permitted to be protected against overcurrent in accordance with 430.28 and 430.53, respectively.

**(G) Conductors from Generator Terminals.** Conductors from generator terminals that meet the size requirement in 445.13 shall be permitted to be protected against overload by the generator overload protective device(s) required by 445.12.

**(H) Battery Conductors.** Overcurrent protection shall be permitted to be installed as close as practicable to the storage battery terminals in an **unclassified** location. Installation of the overcurrent protection within a hazardous **(classified)** location shall also be permitted.

## 240.22 Grounded Conductor

No overcurrent device shall be connected in series with any conductor that is intentionally grounded, unless one of the following two conditions is met:

- (1) The overcurrent device opens all conductors of the circuit, including the grounded conductor, and is designed so that no pole can operate independently.
- (2) Where required by 430.36 or 430.37 for motor overload protection.

## 240.23 Change in Size of Grounded Conductor

Where a change occurs in the size of the ungrounded conductor, a similar change shall be permitted to be made in the size of the grounded conductor.

The requirement in 240.23 acknowledges that the size of the grounded circuit conductor may be increased (e.g., because of voltage drop problems) or reduced to correspond to a reduction made in the size of the ungrounded circuit conductor(s), as in the case of feeder tap conductors, provided that the grounded and ungrounded conductors comprise the same circuit.

## 240.24 Location in or on Premises

**(A) Accessibility.** Overcurrent devices shall be readily accessible and shall be installed so that the center of the grip of the operating handle of the switch or circuit breaker, when in

its highest position, is not more than 2.0 m (6 ft 7 in.) above the floor or working platform, unless one of the following applies:

- (1) For busways, as provided in 368.17(C).
- (2) For supplementary overcurrent protection, as described in 240.10.
- (3) For overcurrent devices, as described in 225.40 and 230.92.
- (4) For overcurrent devices adjacent to utilization equipment that they supply, access shall be permitted to be by portable means.

Section 240.24(A)(4) recognizes the need for overcurrent protection in locations that are not readily accessible, such as above suspended ceilings. It permits overcurrent devices to be located so that they are not readily accessible, as long as they are located next to the appliance, motor, or other equipment they supply and can be reached by using a ladder. For the purposes of this requirement, ready access to the operating handle of a fusible switch or circuit breaker is considered to be not more than 6 ft 7 in. above the finished floor or working platform.

The measurement is made from the center of the device operating handle when the handle is at its highest position. This text parallels the requirement of 404.8(A), which applies to all switches and to circuit breakers used as switches. For information regarding the accessibility of supplementary overcurrent devices, refer to 240.10.

**(B) Occupancy.** Each occupant shall have ready access to all overcurrent devices protecting the conductors supplying that occupancy, unless otherwise permitted in 240.24(B)(1) and (B)(2).

**(1) Service and Feeder Overcurrent Devices.** Where electric service and electrical maintenance are provided by the building management and where these are under continuous building management supervision, the service overcurrent devices and feeder overcurrent devices supplying more than one occupancy shall be permitted to be accessible only to authorized management personnel in the following:

- (1) Multiple-occupancy buildings
- (2) Guest rooms or guest suites

**(2) Branch-Circuit Overcurrent Devices.** Where electric service and electrical maintenance are provided by the building management and where these are under continuous building management supervision, the branch-circuit overcurrent devices supplying any guest rooms or guest suites without permanent provisions for cooking shall be permitted to be accessible only to authorized management personnel.

**(C) Not Exposed to Physical Damage.** Overcurrent devices shall be located where they will not be exposed to physical damage.

Informational Note: See 110.11, Deteriorating Agents.

**(D) Not in Vicinity of Easily Ignitable Material.** Overcurrent devices shall not be located in the vicinity of easily ignitable material, such as in clothes closets.

Section 240.24(D) is aimed at reducing the potential of a fire caused by molten material escaping from an assembly or enclosure housing overcurrent protective devices. Examples of easily ignitable material include, but are not limited to, linen, fabric, and paper products.

**(E) Not Located in Bathrooms.** In dwelling units, dormitories, and guest rooms or guest suites, overcurrent devices, other than supplementary overcurrent protection, shall not be located in bathrooms.

**(F) Not Located over Steps.** Overcurrent devices shall not be located over steps of a stairway.

### III. Enclosures

#### 240.30 General

**(A) Protection from Physical Damage.** Overcurrent devices shall be protected from physical damage by one of the following:

- (1) Installation in enclosures, cabinets, cutout boxes, or equipment assemblies
- (2) Mounting on open-type switchboards, panelboards, or control boards that are in rooms or enclosures free from dampness and easily ignitable material and are accessible only to qualified personnel

To ensure that an overcurrent protective device(s) performs its intended safety function, 240.30(A) requires the devices to be protected against physical damage. Physical damage includes exposure to mechanical injury or exposure to deteriorating agents that adversely affect the operation of the overcurrent protective device. Enclosures for overcurrent protective devices provide a number of functions including protecting the devices against physical damage. Guarding through controlled access is another means of affording protection against physical damage.

**(B) Operating Handle.** The operating handle of a circuit breaker shall be permitted to be accessible without opening a door or cover.

#### 240.32 Damp or Wet Locations

Enclosures for overcurrent devices in damp or wet locations shall comply with 312.2.

#### 240.33 Vertical Position

Enclosures for overcurrent devices shall be mounted in a vertical position unless that is shown to be impracticable. Circuit breaker enclosures shall be permitted to be installed horizontally where the circuit breaker is installed in accordance with 240.81. Listed busway plug-in units shall be permitted to be mounted in orientations corresponding to the busway mounting position.

The general rule of 240.33 requires enclosures for overcurrent devices to be installed in a vertical position. A wall-mounted vertical position for enclosures for overcurrent devices affords easier access, natural hand operation, normal swinging or closing of doors or covers, and legibility of the manufacturer's markings. In addition, this section does not permit a panelboard or fusible switch enclosure to be installed in a horizontal position such that the back of the enclosure is mounted on the ceiling or the floor. Compliance with the up position of the handle being on or closed, and the down position of the handle being off or open, in accordance with 240.81, limits the number of pole spaces available in a panelboard where its cabinet is mounted in a horizontal position on or in a wall.

### IV. Disconnecting and Guarding

#### 240.40 Disconnecting Means for Fuses

Cartridge fuses in circuits of any voltage where accessible to other than qualified persons, and all fuses in circuits over 150 volts to ground, shall be provided with a disconnecting means on their supply side so that each circuit containing fuses can be independently disconnected from the source of power. A current-limiting device without a disconnecting means shall be permitted on the supply side of the service disconnecting means as permitted by 230.82. A single disconnecting means shall be permitted on the supply side of more than one set of fuses as permitted by 430.112, Exception, for group operation of motors and 424.22(C) for fixed electric space-heating equipment.

A single disconnect switch is permitted by 240.40 to serve more than one set of fuses, such as in multimotor installations or for electric space-heating equipment where the heating element load is required to be subdivided, each element with its own set of fuses. The installation of cable limiters or similar current-limiting devices on the supply side of the service disconnecting means is permitted by 230.82(1). No

disconnecting means is required on the supply side of such devices.

### 240.41 Arcing or Suddenly Moving Parts

Arcing or suddenly moving parts shall comply with 240.41(A) and (B).

**(A) Location.** Fuses and circuit breakers shall be located or shielded so that persons will not be burned or otherwise injured by their operation.

**(B) Suddenly Moving Parts.** Handles or levers of circuit breakers, and similar parts that may move suddenly in such a way that persons in the vicinity are likely to be injured by being struck by them, shall be guarded or isolated.

Arcing or sudden-moving parts associated with open-type switchboards or control boards can result in injury to personnel in the vicinity of this type equipment. To comply with workplace safety requirements such as those contained in *NFPA 70E*®, *Standard for Electrical Safety in the Workplace*®, open switchboards and control boards must be under competent supervision and accessible only to persons qualified to work on or in the vicinity of such equipment. Fuses or circuit breakers must be located or shielded so that, under an abnormal condition, the subsequent arc across the opening device will not injure persons in the vicinity.

Guardrails are provided in the vicinity of disconnecting means as a means of protecting persons against injury caused by suddenly moving handles of overcurrent protective devices. Switchboards equipped with removable handles help mitigate this personal injury hazard. See Article 100 for the definition of *guarded*. See also 110.27 for the guarding of live parts (600 volts, nominal, or less).

## V. Plug Fuses, Fuseholders, and Adapters

### 240.50 General

**(A) Maximum Voltage.** Plug fuses shall be permitted to be used in the following circuits:

- (1) Circuits not exceeding 125 volts between conductors
- (2) Circuits supplied by a system having a grounded neutral point where the line-to-neutral voltage does not exceed 150 volts

Section 240.50(A) specifies that plug fuses can be installed in circuits supplied by 120/240-volt, single-phase, 3-wire systems and by 208Y/120-volt, 3-phase, 4-wire systems.

**(B) Marking.** Each fuse, fuseholder, and adapter shall be marked with its ampere rating.

**(C) Hexagonal Configuration.** Plug fuses of 15-ampere and lower rating shall be identified by a hexagonal configuration of the window, cap, or other prominent part to distinguish them from fuses of higher ampere ratings.

The 10- and 15-ampere plug fuses shown in Exhibit 240.11 are equipped with the hexagonal window required by 240.50(C). The 10-ampere fuse is a Type S plug fuse, which when used with its corresponding fuseholder or adapter, cannot be interchanged with a higher rated fuse.

**EXHIBIT 240.11** Two plug fuses and a Type S fuse. (Courtesy of Cooper Bussmann, a division of Cooper Industries PLC)

**(D) No Energized Parts.** Plug fuses, fuseholders, and adapters shall have no exposed energized parts after fuses or fuses and adapters have been installed.

**(E) Screw Shell.** The screw shell of a plug-type fuseholder shall be connected to the load side of the circuit.

Exhibit 240.12 shows a Type S nonrenewable plug fuse adapter designed to meet the requirements of 240.53 and 240.54. To prevent installation of a fuse exceeding the ampacity of the conductor being protected, the adapter will not accept Type S plug fuses having an ampere rating other than that for which it has been specifically designed.

### 240.51 Edison-Base Fuses

**(A) Classification.** Plug fuses of the Edison-base type shall be classified at not over 125 volts and 30 amperes and below.

**EXHIBIT 240.12** Type S nonrenewable plug fuse adapter.  
(Courtesy of Cooper Bussmann, a division of Cooper Industries PLC)

**(B) Replacement Only.** Plug fuses of the Edison-base type shall be used only for replacements in existing installations where there is no evidence of overfusing or tampering.

### 240.52 Edison-Base Fuseholders

Fuseholders of the Edison-base type shall be installed only where they are made to accept Type S fuses by the use of adapters.

### 240.53 Type S Fuses

Type S fuses shall be of the plug type and shall comply with 240.53(A) and (B).

**(A) Classification.** Type S fuses shall be classified at not over 125 volts and 0 to 15 amperes, 16 to 20 amperes, and 21 to 30 amperes.

**(B) Noninterchangeable.** Type S fuses of an ampere classification as specified in 240.53(A) shall not be interchangeable with a lower ampere classification. They shall be designed so that they cannot be used in any fuseholder other than a Type S fuseholder or a fuseholder with a Type S adapter inserted.

### 240.54 Type S Fuses, Adapters, and Fuseholders

**(A) To Fit Edison-Base Fuseholders.** Type S adapters shall fit Edison-base fuseholders.

**(B) To Fit Type S Fuses Only.** Type S fuseholders and adapters shall be designed so that either the fuseholder itself or the fuseholder with a Type S adapter inserted cannot be used for any fuse other than a Type S fuse.

**(C) Nonremovable.** Type S adapters shall be designed so that once inserted in a fuseholder, they cannot be removed.

**(D) Nontamperable.** Type S fuses, fuseholders, and adapters shall be designed so that tampering or shunting (bridging) would be difficult.

**(E) Interchangeability.** Dimensions of Type S fuses, fuseholders, and adapters shall be standardized to permit interchangeability regardless of the manufacturer.

## VI. Cartridge Fuses and Fuseholders

### 240.60 General

**(A) Maximum Voltage — 300-Volt Type.** Cartridge fuses and fuseholders of the 300-volt type shall be permitted to be used in the following circuits:

- (1) Circuits not exceeding 300 volts between conductors
- (2) Single-phase line-to-neutral circuits supplied from a 3-phase, 4-wire, solidly grounded neutral source where the line-to-neutral voltage does not exceed 300 volts

**(B) Noninterchangeable — 0–6000-Ampere Cartridge Fuseholders.** Fuseholders shall be designed so that it will be difficult to put a fuse of any given class into a fuseholder that is designed for a current lower, or voltage higher, than that of the class to which the fuse belongs. Fuseholders for current-limiting fuses shall not permit insertion of fuses that are not current-limiting.

**(C) Marking.** Fuses shall be plainly marked, either by printing on the fuse barrel or by a label attached to the barrel showing the following:

- (1) Ampere rating
- (2) Voltage rating
- (3) Interrupting rating where other than 10,000 amperes
- (4) Current limiting where applicable
- (5) The name or trademark of the manufacturer

The interrupting rating shall not be required to be marked on fuses used for supplementary protection.

Exhibit 240.13 shows two examples of Class G fuses rated 300 volts that bear the markings required by 240.60(C). Class H-type cartridge fuses have an interrupting capacity (IC) rating of 10,000 amperes, which need not be marked on the fuse. However, Class CC, G, J, K, L, R, and T cartridge

**EXHIBIT 240.13** Two fuses rated 300 volts with marking to indicate they are Class G. (Courtesy of Cooper Bussmann, a division of Cooper Industries PLC)

fuses exceed the 10,000-ampere IC rating and must be marked with the IC rating. Section 240.83(C) requires that the IC rating for circuit breakers for other than 5000 amperes be indicated on the circuit breaker. Fuses or circuit breakers used for supplementary overcurrent protection of fluorescent fixtures, semiconductor rectifiers, motor-operated appliances, and so on, need not be marked for IC. See the commentary following 110.9 and 110.10.

**(D) Renewable Fuses.** Class H cartridge fuses of the renewable type shall be permitted to be used only for replacement in existing installations where there is no evidence of overfusing or tampering.

Class H renewable fuses are now permitted by 240.60(D) to be used only as replacements in existing installations. Where overfusing and/or tampering are detected with an existing installation, the use of nonrenewable fuses as a replacement is mandatory. An important consideration in the use of the traditional Class H renewable fuse is its 10,000-ampere interrupting rating. Caution must be exercised where the use of renewable fuses is contemplated, because the manufacturer's directions provided in some modern fusible switches do not permit the use of renewable fuses or strongly recommend against their use.

### 240.61 Classification

Cartridge fuses and fuseholders shall be classified according to voltage and amperage ranges. Fuses rated 600 volts, nominal, or less shall be permitted to be used for voltages at or below their ratings.

See Part II of Article 100 for definitions covering fuses rated over 600 volts. Section 490.21(B) covers applications of high-voltage fuses and fuseholders.

## VII. Circuit Breakers

### 240.80 Method of Operation

Circuit breakers shall be trip free and capable of being closed and opened by manual operation. Their normal method of operation by other than manual means, such as electrical or pneumatic, shall be permitted if means for manual operation are also provided.

### 240.81 Indicating

Circuit breakers shall clearly indicate whether they are in the open “off” or closed “on” position.

Where circuit breaker handles are operated vertically rather than rotationally or horizontally, the “up” position of the handle shall be the “on” position.

Section 240.81 standardizes switching operation of circuit breakers. In accordance with this requirement, a switching handle in the downward position places the device in an open or off position and the downward position is intuitively viewed by most as being the off position. Opening or turning off a circuit breaker or switch is generally the initial operation in de-energizing equipment or circuit conductors for servicing or maintenance. Although this standardized position requirement exists in the *Code*, the provisions of *NFPA 70E, Standard for Electrical Safety in the Workplace*, contain other steps that have to be followed to ascertain that electrical conductors or circuit parts are de-energized (placed in an *electrically safe work condition* per *NFPA 70E*). See 240.83(D), 404.11, and 410.141(A) for requirements for circuit breakers used as switches.

### 240.82 Nontamperable

A circuit breaker shall be of such design that any alteration of its trip point (calibration) or the time required for its operation requires dismantling of the device or breaking of a seal for other than intended adjustments.

### 240.83 Marking

**(A) Durable and Visible.** Circuit breakers shall be marked with their ampere rating in a manner that will be durable and visible after installation. Such marking shall be permitted to be made visible by removal of a trim or cover.

**(B) Location.** Circuit breakers rated at 100 amperes or less and 600 volts or less shall have the ampere rating molded,

stamped, etched, or similarly marked into their handles or escutcheon areas.

**(C) Interrupting Rating.** Every circuit breaker having an interrupting rating other than 5000 amperes shall have its interrupting rating shown on the circuit breaker. The interrupting rating shall not be required to be marked on circuit breakers used for supplementary protection.

**(D) Used as Switches.** Circuit breakers used as switches in 120-volt and 277-volt fluorescent lighting circuits shall be listed and shall be marked SWD or HID. Circuit breakers used as switches in high-intensity discharge lighting circuits shall be listed and shall be marked as HID.

Circuit breakers marked “SWD,” as required by 240.83(D), are 15- or 20-ampere breakers that have been subjected to additional endurance and temperature testing to assess their ability for use as the regular control device for fluorescent lighting circuits. Circuit breakers marked “HID” are also acceptable for switching applications, and this marking must be on circuit breakers used as the regular switching device to control high-intensity discharge (HID) lighting such as mercury vapor, high-pressure or low-pressure sodium, or metal halide lighting. Circuit breakers marked “HID” can be used for switching both high-intensity discharge and fluorescent lighting loads; however, a circuit breaker marked “SWD” can be used only as a switching device for fluorescent lighting loads.

**(E) Voltage Marking.** Circuit breakers shall be marked with a voltage rating not less than the nominal system voltage that is indicative of their capability to interrupt fault currents between phases or phase to ground.

### 240.85 Applications

A circuit breaker with a straight voltage rating, such as 240V or 480V, shall be permitted to be applied in a circuit in which the nominal voltage between any two conductors does not exceed the circuit breaker’s voltage rating. A two-pole circuit breaker shall not be used for protecting a 3-phase, corner-grounded delta circuit unless the circuit breaker is marked 1 $\phi$ –3 $\phi$  to indicate such suitability.

A circuit breaker with a slash rating, such as 120/240V or 480Y/277V, shall be permitted to be applied in a solidly grounded circuit where the nominal voltage of any conductor to ground does not exceed the lower of the two values of the circuit breaker’s voltage rating and the nominal voltage between any two conductors does not exceed the higher value of the circuit breaker’s voltage rating.

**Informational Note:** Proper application of molded case circuit breakers on 3-phase systems, other than solidly grounded wye, particularly on corner grounded delta sys-

tems, considers the circuit breakers’ individual pole-interrupting capability.

The requirement of 240.85 ensures that circuit breakers are properly applied within their voltage rating. A circuit breaker marked 480Y/277V is not intended for use on a 480-volt system with up to 480 volts to ground, such as a 480-volt circuit derived from a corner-grounded, delta-connected system. A circuit breaker marked either 480V or 600V should be used on such a system. Similarly, a circuit breaker marked 120/240V is not intended for use on a delta-connected 240-volt circuit. A 240-volt, 480-volt, or 600-volt circuit breaker should be used on such a circuit. The slash (/) between the lower and higher voltage ratings in the marking indicates that the circuit breaker has been tested for use on a circuit with the higher voltage between phases and with the lower voltage to ground.

### 240.86 Series Ratings

Where a circuit breaker is used on a circuit having an available fault current higher than the marked interrupting rating by being connected on the load side of an acceptable overcurrent protective device having a higher rating, the circuit breaker shall meet the requirements specified in (A) or (B), and (C).

Section 240.86 covers the interrupting ratings of circuit breakers that are installed as part of a series rated system. The general requirement for interrupting ratings of circuit protective devices is contained in 110.9. A series rated system is a combination of circuit breakers or a combination of fuses and circuit breakers that can be applied at available short-circuit levels above the interrupting rating of the load-side circuit breakers but not above that of the main or line-side device. Series rated systems can consist of fuses that protect circuit breakers or of circuit breakers that protect circuit breakers. The arrangement of protective components in a series rated system can be as specified in 240.86(A) for engineered systems applied to existing installations or in 240.86(B) for tested combinations that can be applied in any new or existing installation.

**(A) Selected Under Engineering Supervision in Existing Installations.** The series rated combination devices shall be selected by a licensed professional engineer engaged primarily in the design or maintenance of electrical installations. The selection shall be documented and stamped by the professional engineer. This documentation shall be available to those authorized to design, install, inspect, maintain, and operate the system. This series combination rating, including identification of the upstream device, shall be field marked on the end use equipment.

For calculated applications, the engineer shall ensure that the downstream circuit breaker(s) that are part of the series combination remain passive during the interruption period of the line side fully rated, current-limiting device.

The provisions of 240.86(A) allow for an engineering solution at existing facilities where an increase in the available fault current (due to factors such as increases in transformer size, lowering of transformer impedances, and changes in utility distribution systems) puts the existing circuit overcurrent protection equipment at peril in regard to interrupting fault currents as required by 110.9. The objective of this “engineered system” is to maintain compliance with 110.9 by redesigning the overcurrent protection scheme to accommodate the increase in available fault current and not having to undertake a wholesale replacement of electrical distribution equipment. Where the increase in fault current causes existing equipment to be “underrated,” the engineering approach is to provide upstream protection that functions in concert with the existing protective devices to safely open the circuit under fault conditions. The requirement specifies that the design of such systems is to be performed only by licensed professional engineers whose credentials substantiate their ability to perform this type of engineering. Documentation in the form of stamped drawings and field marking of end-use equipment to indicate it is a component of a series rated system is required.

Designing a series rated system requires careful consideration of the fault-clearing characteristics of the existing protective devices and their ability to interact with the newly installed upstream protective device(s) when subjected to fault conditions. This new provision does not ensure that an engineered series rated system can be applied to all existing installations. The operating parameters of the existing overcurrent protection equipment dictate what can be done in a field-engineered protection scheme.

Compatibility with series rated systems will in all likelihood be limited to circuit breakers that (1) remain closed during the interruption period of the fully rated OCPD installed on their line side and (2) have an interrupting rating that is not less than the let-through current of an upstream protective device (such as a current-limiting fuse). In those cases where the opening of a circuit breaker, under any level of fault current, begins in less than  $\frac{1}{2}$  cycle, the use of a field-engineered series rated system will likely be contrary to acceptable application practices specified by the circuit breaker manufacturer. The passivity of the downstream circuit breakers during interruption of a fault by an upstream device has to be ensured by the design engineer in order for this engineered approach to be employed. Where there is any doubt about the proper application of existing downstream circuit breakers with new upstream overcurrent protective devices, the manufacturers of the existing circuit

breakers and the new upstream overcurrent protective devices must be consulted.

The safety objective of any overcurrent protection scheme is to ensure compliance with 110.9.

**(B) Tested Combinations.** The combination of line-side overcurrent device and load-side circuit breaker(s) is tested and marked on the end use equipment, such as switchboards and panelboards.

Informational Note to (A) and (B): See 110.22 for marking of series combination systems.

Section 240.86(B) requires that, when a series rating is used, the switchboards, panelboards, and load centers be marked for use with the series rated combinations that may be used. Therefore, the enclosures must have a label affixed by the equipment manufacturer that provides the series rating of the combination(s). Because there is often not enough room in the equipment to show all the legitimate series rated combinations, UL 67, *Standard for Panelboards*, allows a bulletin to be referenced and supplied with the panelboard. These bulletins typically provide all the acceptable combinations. The installer of a series rated system must also provide the additional labeling on equipment enclosures required by 110.22, indicating that the equipment has been applied in a series rated system.

**(C) Motor Contribution.** Series ratings shall not be used where

- (1) Motors are connected on the load side of the higher-rated overcurrent device and on the line side of the lower-rated overcurrent device, and
- (2) The sum of the motor full-load currents exceeds 1 percent of the interrupting rating of the lower-rated circuit breaker.

The requirements in 240.86(C) limit the use of series rated systems in which motors are connected between the line-side (protecting) device and the load-side (protected) circuit breaker. Section 240.86(C)(2) requires that series ratings developed under the parameters of either 240.86(A) or (B) are not to be used where the sum of motor full-load currents exceeds 1 percent of the interrupting rating of the load-side (protected) circuit breaker, as illustrated in Exhibit 240.14.

## 240.87 Noninstantaneous Trip

Where a circuit breaker is used without an instantaneous trip, documentation shall be available to those authorized to

**EXHIBIT 240.14** Example of installation where level of motor contribution exceeds 1 percent of interrupting rating for the lowest-rated circuit breaker in this series rated system.

design, install, operate, or inspect the installation as to the location of the circuit breaker(s).

Where a circuit breaker is utilized without an instantaneous trip, one of the following or approved equivalent means shall be provided:

- (1) Zone-selective interlocking
- (2) Differential relaying
- (3) Energy-reducing maintenance switching with local status indicator

**Informational Note:** An energy-reducing maintenance switch allows a worker to set a circuit breaker trip unit to “no intentional delay” to reduce the clearing time while the worker is working within an arc-flash boundary as defined in NFPA 70E-2009, *Standard for Electrical Safety in the Workplace*, and then to set the trip unit back to a normal setting after the potentially hazardous work is complete.

Where a circuit breaker trip unit does not provide the capability for an instantaneous response to a short-circuit, 240.87 requires that (1) the location of the device in the electrical system be documented, and (2) a means be provided in the system to limit the energy that personnel may be exposed to while working on energized equipment.

Circuit breakers without the capability of an instantaneous response can be used to selectively coordinate with other overcurrent protective devices where required by the *Code* or where incorporated as part of an electrical system design. However, a longer protective device opening time can expose the person(s) who may have initiated the fault while working on energized electrical equipment to more incident energy, thus increasing the severity of the hazard.

This section identifies three specific methods that can be used to comply with this requirement and also permits use of an approved equivalent. As defined in Article 100 *approved* means acceptable to the authority having jurisdiction. Zone-selective interlocking and differential relaying are methods that can be implemented as part of the system design and do not require any manual intervention. An energy-reducing maintenance switch is a means by which an intentional delay in the opening of a circuit breaker can be overridden while maintenance, service, or diagnostic tasks are being performed, and then restored upon completion of the tasks to enable the system to be selectively coordinated or for other system design purposes. The *Code* does not prohibit the use of these methods to limit fault current in systems where circuit breakers having an instantaneous capability are installed and adjusted to allow for a longer clearing time, but this is a design consideration and is not required by this section.

Exhibit 240.15 is an example of an electronic trip unit for a circuit breaker employing an energy-reducing maintenance switch in addition to means for adjusting other settings. The function of the energy reduction maintenance switch is to override any settings that intentionally delay the opening time of the circuit breaker. A selectively coordinated electrical system is one example of where the response time adjustments available on some circuit breakers are set to allow for localization of a fault in the circuit. When these

**EXHIBIT 240.15** An electronic trip unit for a circuit breaker that has its instantaneous setting set to “Off” and that incorporates an energy-reducing maintenance setting. (Courtesy of Eaton Corporation)

settings are overridden, the circuit breaker responds faster to a downstream fault in the circuit. The faster response time provides the important benefit of reducing the level of incident energy that personnel may be exposed to when tasks are being performed within the arc flash boundary (see *NFPA 70E* for definition of *arc flash boundary*). A local status indicator (LED for “maintenance mode”) provides qualified persons with the indication that trip settings have been adjusted to reduce incident energy should a fault occur anywhere electrically downstream of the device.

Once the task has been completed, any settings that previously introduced an intentional delay in the circuit breaker clearing time can be restored.

## VIII. Supervised Industrial Installations

### 240.90 General

Overcurrent protection in areas of supervised industrial installations shall comply with all of the other applicable provisions of this article, except as provided in Part VIII. The provisions of Part VIII shall be permitted only to apply to those portions of the electrical system in the supervised industrial installation used exclusively for manufacturing or process control activities.

Part VIII provides alternative approaches to overcurrent protection for low-voltage distribution systems (600 volts, nominal, and under) that supply large manufacturing plants or industrial processes. For more information on *supervised industrial installation*, see the commentary following 240.2. Section 240.21 contains the requirements that specify the point in the circuit at which overcurrent protection for conductors is to be located. The general rule of 240.21 is that conductors are to be protected at the point they receive their supply, and 240.21(B) and (C) contain provisions that allow the overcurrent protection for feeders and transformer secondary conductors to be provided at other than the point of supply. The rules in Part VIII modify the 240.21(B) and (C) requirements based on the condition that only qualified personnel monitor and maintain the installation. Included in the requirements of 240.92(A) through (D) are provisions for longer conductor lengths, for use of differential relays as the means for providing short-circuit ground-fault protection, and for use of up to six circuit breakers or fuses as the overload protection for outside feeder taps and outside transformer secondary conductors.

### 240.91 Protection of Conductors

Conductors shall be protected in accordance with 240.91(A) or (B).

**(A) General.** Conductors shall be protected in accordance with 240.4.

**(B) Devices Rated Over 800 Amperes.** Where the overcurrent device is rated over 800 amperes, the ampacity of the conductors it protects shall be equal to or greater than 95 percent of the rating of the overcurrent device specified in 240.6 in accordance with (B)(1) and (2).

- (1) The conductors are protected within recognized time vs. current limits for short-circuit currents
- (2) All equipment in which the conductors terminate is listed and marked for the application

This provision is only permitted to be used where the facility or plant is a *supervised industrial installation* as defined in 240.2. Conductors protected by overcurrent protective devices rated more than 800 amperes can have an ampacity that is 95 percent of the rating of the overcurrent protective device. For example, if the OCPD is rated 1000 amperes, the conductor ampacity cannot be less than 950 amperes. In order to apply this provision, calculations have to be made in order to ascertain that the conductors are adequately protected during the time it takes for the overcurrent protective device to open due to a short circuit. In addition, the device and equipment in which the conductors terminate are required to be evaluated and listed by a qualified electrical testing laboratory for this specific application. This provision does not obviate the requirements in Articles 210, 215, and 230 that require branch circuit, feeder, and service conductors to have an ampacity not less than the calculated load being supplied.

### 240.92 Location in Circuit

An overcurrent device shall be connected in each ungrounded circuit conductor as required in 240.92(A) through (E).

**(A) Feeder and Branch-Circuit Conductors.** Feeder and branch-circuit conductors shall be protected at the point the conductors receive their supply as permitted in 240.21 or as otherwise permitted in 240.92(B), (C), (D), or (E).

**(B) Feeder Taps.** For feeder taps specified in 240.21(B)(2), (B)(3), and (B)(4), the tap conductors shall be permitted to be sized in accordance with Table 240.92(B).

**(C) Transformer Secondary Conductors of Separately Derived Systems.** Conductors shall be permitted to be connected to a transformer secondary of a separately derived system, without overcurrent protection at the connection, where the conditions of 240.92(C)(1), (C)(2), and (C)(3) are met.

**(1) Short-Circuit and Ground-Fault Protection.** The conductors shall be protected from short-circuit and ground-fault

**TABLE 240.92(B) Tap Conductor Short-Circuit Current Ratings.**

Tap conductors are considered to be protected under short-circuit conditions when their short-circuit temperature limit is not exceeded. Conductor heating under short-circuit conditions is determined by (1) or (2):

(1) *Short-Circuit Formula for Copper Conductors*

$$(I^2/A^2)t = 0.0297 \log_{10} [(T_2 + 234)/(T_1 + 234)]$$

(2) *Short-Circuit Formula for Aluminum Conductors*

$$(I^2/A^2)t = 0.0125 \log_{10} [(T_2 + 228)/(T_1 + 228)]$$

where:

$I$  = short-circuit current in amperes

$A$  = conductor area in circular mils

$t$  = time of short circuit in seconds (for times less than or equal to 10 seconds)

$T_1$  = initial conductor temperature in degrees Celsius.

$T_2$  = final conductor temperature in degrees Celsius.

Copper conductor with paper, rubber, varnished cloth insulation,  
 $T_2 = 200$

Copper conductor with thermoplastic insulation,  $T_2 = 150$

Copper conductor with cross-linked polyethylene insulation,  
 $T_2 = 250$

Copper conductor with ethylene propylene rubber insulation,  
 $T_2 = 250$

Aluminum conductor with paper, rubber, varnished cloth insulation,  $T_2 = 200$

Aluminum conductor with thermoplastic insulation,  $T_2 = 150$

Aluminum conductor with cross-linked polyethylene insulation,  
 $T_2 = 250$

Aluminum conductor with ethylene propylene rubber insulation,  
 $T_2 = 250$

conditions by complying with one of the following conditions:

- (1) The length of the secondary conductors does not exceed 30 m (100 ft) and the transformer primary overcurrent device has a rating or setting that does not exceed 150 percent of the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio.
- (2) The conductors are protected by a differential relay with a trip setting equal to or less than the conductor ampacity.

**Informational Note:** A differential relay is connected to be sensitive only to short-circuit or fault currents within the protected zone and is normally set much lower than the conductor ampacity. The differential relay is connected to trip protective devices that de-energize the protected conductors if a short-circuit condition occurs.

- (3) The conductors shall be considered to be protected if calculations, made under engineering supervision, de-

termine that the system overcurrent devices will protect the conductors within recognized time vs. current limits for all short-circuit and ground-fault conditions.

**(2) Overload Protection.** The conductors shall be protected against overload conditions by complying with one of the following:

- (1) The conductors terminate in a single overcurrent device that will limit the load to the conductor ampacity.
- (2) The sum of the overcurrent devices at the conductor termination limits the load to the conductor ampacity. The overcurrent devices shall consist of not more than six circuit breakers or sets of fuses, mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard. There shall be no more than six overcurrent devices grouped in any one location.
- (3) Overcurrent relaying is connected [with a current transformer(s), if needed] to sense all of the secondary conductor current and limit the load to the conductor ampacity by opening upstream or downstream devices.
- (4) Conductors shall be considered to be protected if calculations, made under engineering supervision, determine that the system overcurrent devices will protect the conductors from overload conditions.

**(3) Physical Protection.** The secondary conductors are protected from physical damage by being enclosed in an approved raceway or by other approved means.

**(D) Outside Feeder Taps.** Outside conductors shall be permitted to be tapped to a feeder or to be connected at a transformer secondary, without overcurrent protection at the tap or connection, where all the following conditions are met:

- (1) The conductors are protected from physical damage in an approved manner.
- (2) The sum of the overcurrent devices at the conductor termination limits the load to the conductor ampacity. The overcurrent devices shall consist of not more than six circuit breakers or sets of fuses mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard. There shall be no more than six overcurrent devices grouped in any one location.
- (3) The tap conductors are installed outdoors of a building or structure except at the point of load termination.
- (4) The overcurrent device for the conductors is an integral part of a disconnecting means or shall be located immediately adjacent thereto.
- (5) The disconnecting means for the conductors are installed at a readily accessible location complying with one of the following:
  - a. Outside of a building or structure
  - b. Inside, nearest the point of entrance of the conductors

- c. Where installed in accordance with 230.6, nearest the point of entrance of the conductors

**(E) Protection by Primary Overcurrent Device.** Conductors supplied by the secondary side of a transformer shall be permitted to be protected by overcurrent protection provided on the primary (supply) side of the transformer, provided the primary device time–current protection characteristic, multiplied by the maximum effective primary-to-secondary transformer voltage ratio, effectively protects the secondary conductors.

## IX. Overcurrent Protection Over 600 Volts, Nominal

### 240.100 Feeders and Branch Circuits

**(A) Location and Type of Protection.** Feeder and branch-circuit conductors shall have overcurrent protection in each ungrounded conductor located at the point where the conductor receives its supply or at an alternative location in the circuit when designed under engineering supervision that includes but is not limited to considering the appropriate fault studies and time–current coordination analysis of the protective devices and the conductor damage curves. The overcurrent protection shall be permitted to be provided by either 240.100(A)(1) or (A)(2).

**(1) Overcurrent Relays and Current Transformers.** Circuit breakers used for overcurrent protection of 3-phase circuits shall have a minimum of three overcurrent relay elements operated from three current transformers. The separate overcurrent relay elements (or protective functions) shall be permitted to be part of a single electronic protective relay unit.

On 3-phase, 3-wire circuits, an overcurrent relay element in the residual circuit of the current transformers shall be permitted to replace one of the phase relay elements.

An overcurrent relay element, operated from a current transformer that links all phases of a 3-phase, 3-wire circuit, shall be permitted to replace the residual relay element and one of the phase-conductor current transformers. Where the neutral conductor is not regrounded on the load side of the circuit as permitted in 250.184(B), the current transformer shall be permitted to link all 3-phase conductors and the grounded circuit conductor (neutral).

**(2) Fuses.** A fuse shall be connected in series with each ungrounded conductor.

**(B) Protective Devices.** The protective device(s) shall be capable of detecting and interrupting all values of current that can occur at their location in excess of their trip-setting or melting point.

**(C) Conductor Protection.** The operating time of the protective device, the available short-circuit current, and the conductor used shall be coordinated to prevent damaging or dangerous temperatures in conductors or conductor insulation under short-circuit conditions.

### 240.101 Additional Requirements for Feeders

**(A) Rating or Setting of Overcurrent Protective Devices.** The continuous ampere rating of a fuse shall not exceed three times the ampacity of the conductors. The long-time trip element setting of a breaker or the minimum trip setting of an electronically actuated fuse shall not exceed six times the ampacity of the conductor. For fire pumps, conductors shall be permitted to be protected for overcurrent in accordance with 695.4(B)(2).

**(B) Feeder Taps.** Conductors tapped to a feeder shall be permitted to be protected by the feeder overcurrent device where that overcurrent device also protects the tap conductor.

## I. General

### 250.1 Scope

This article covers general requirements for grounding and bonding of electrical installations, and the specific requirements in (1) through (6).

- (1) Systems, circuits, and equipment required, permitted, or not permitted to be grounded
- (2) Circuit conductor to be grounded on grounded systems
- (3) Location of grounding connections
- (4) Types and sizes of grounding and bonding conductors and electrodes
- (5) Methods of grounding and bonding
- (6) Conditions under which guards, isolation, or insulation may be substituted for grounding

Informational Note: See Figure 250.1 for information on the organization of Article 250 covering grounding and bonding requirements.

The title of Article 250, *Grounding and Bonding*, conveys that grounding and bonding are two separate concepts; however, they are not mutually exclusive and in many cases are directly interrelated through the requirements of Article 250.

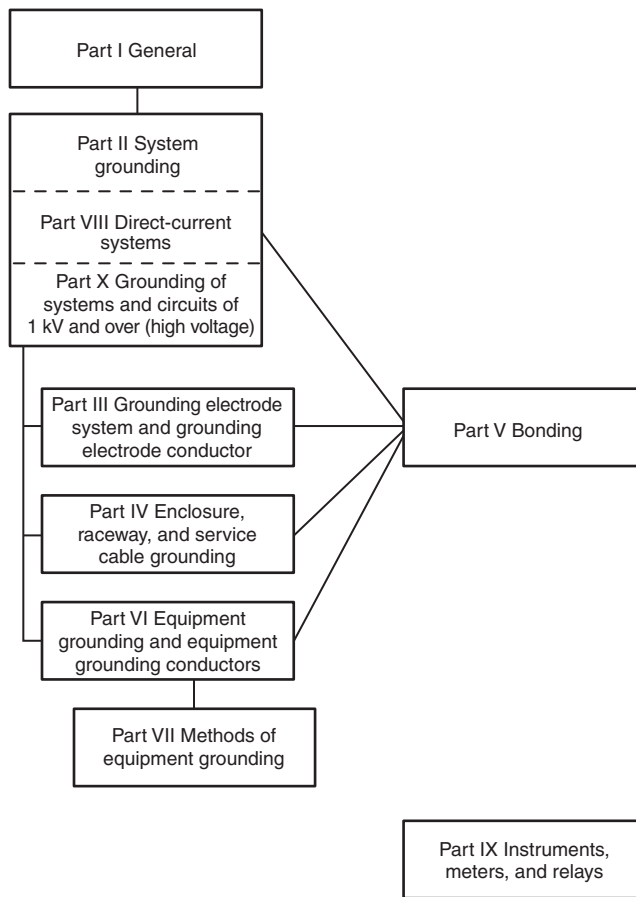

FIGURE 250.1 Grounding and Bonding.

## 250.2 Definitions

**Bonding Jumper, Supply-Side.** A conductor installed on the supply side of a service or within a service equipment enclosure(s), or for a separately derived system, that ensures the required electrical conductivity between metal parts required to be electrically connected.

As implied by the term, *supply-side bonding jumpers* are used to bond electrical equipment containing conductors installed on the line side or supply side of a service disconnecting means and overcurrent protective device(s) or conductors installed between the source of a separately derived system and the first system disconnecting means and overcurrent protective device(s). Metal equipment enclosures, metal raceways, and metal cable trays are examples of equipment containing supply-side conductors that are required to be bonded. Where bonding jumpers are used, they are to be installed and sized as specified in 250.102(A), (B), (C), and (E). Bonding jumpers installed on the load-side of a

service, feeder, or branch-circuit overcurrent protective device are *equipment bonding jumpers*.

**Effective Ground-Fault Current Path.** An intentionally constructed, low-impedance electrically conductive path designed and intended to carry current under ground-fault conditions from the point of a ground fault on a wiring system to the electrical supply source and that facilitates the operation of the overcurrent protective device or ground-fault detectors on high-impedance grounded systems.

**Ground-Fault Current Path.** An electrically conductive path from the point of a ground fault on a wiring system through normally non-current-carrying conductors, equipment, or the earth to the electrical supply source.

Informational Note: Examples of ground-fault current paths could consist of any combination of equipment grounding conductors, metallic raceways, metallic cable sheaths, electrical equipment, and any other electrically conductive material such as metal water and gas piping, steel framing members, stucco mesh, metal ducting, reinforcing steel, shields of communications cables, and the earth itself.

One of the most important aspects of proper application of Article 250 requirements is understanding the definitions of terms related to bonding and grounding that are used throughout the *Code*. Some of the most basic and widely used terms are *bonded*, *grounded*, *grounded conductor*, *equipment grounding conductor*, *grounding electrode*, and *grounding electrode conductor*. These terms are defined in Article 100.

## 250.3 Application of Other Articles

For other articles applying to particular cases of installation of conductors and equipment, grounding and bonding requirements are identified in Table 250.3 that are in addition to, or modifications of, those of this article.

## 250.4 General Requirements for Grounding and Bonding

The following general requirements identify what grounding and bonding of electrical systems are required to accomplish. The prescriptive methods contained in Article 250 shall be followed to comply with the performance requirements of this section.

Section 250.4 provides the performance requirements for grounding and bonding of electrical systems and equipment.

**TABLE 250.3 Additional Grounding and Bonding Requirements**

Conductor/Equipment	Article	Section
Agricultural buildings		547.9 and 547.10
Audio signal processing, amplification, and reproduction equipment		640.7
Branch circuits		210.5, 210.6, 406.3
Cablebus		370.9
Cable trays	392	392.60
Capacitors		460.10, 460.27
Circuits and equipment operating at less than 50 volts	720	
Communications circuits	800	
Community antenna television and radio distribution systems		820.93, 820.100, 820.103
Conductors for general wiring	310	
Cranes and hoists	610	
Electrically driven or controlled irrigation machines		675.11(C), 675.12, 675.13, 675.14, 675.15
Electric signs and outline lighting	600	
Electrolytic cells	668	
Elevators, dumbwaiters, escalators, moving walks, wheelchair lifts, and stairway chairlifts	620	
Fixed electric heating equipment for pipelines and vessels		427.29, 427.48
Fixed outdoor electric deicing and snow-melting equipment		426.27
Flexible cords and cables		400.22, 400.23
Floating buildings		553.8, 553.10, 553.11
Grounding-type receptacles, adapters, cord connectors, and attachment plugs		406.9
Hazardous (classified) locations	500–517	
Health care facilities	517	
Induction and dielectric heating equipment	665	
Industrial machinery	670	
Information technology equipment		645.15
Intrinsically safe systems		504.50
Luminaires and lighting equipment		410.40, 410.42, 410.46, 410.155(B)
Luminaires, lampholders, and lamps	410	
Marinas and boatyards		555.15
Mobile homes and mobile home park	550	
Motion picture and television studios and similar locations		530.20, 530.64(B)
Motors, motor circuits, and controllers	430	
Natural and artificially made bodies of water	682	682.30, 682.31, 682.32, 682.33
Outlet, device, pull, and junction boxes; conduit bodies; and fittings		314.4, 314.25
Over 600 volts, nominal, underground wiring methods		300.50(C)
Panelboards		408.40
Pipe organs	650	
Radio and television equipment	810	
Receptacles and cord connectors		406.3
Recreational vehicles and recreational vehicle parks	551	
Services	230	
Solar photovoltaic systems		690.41, 690.42, 690.43, 690.45, 690.47
Swimming pools, fountains, and similar installations	680	
Switchboards and panelboards		408.3(D)
Switches		404.12
Theaters, audience areas of motion picture and television studios, and similar locations		520.81
Transformers and transformer vaults		450.10
Use and identification of grounded conductors	200	
X-ray equipment	660	517.78

Performance-based requirements provide an overall objective without stating the specifics for accomplishing that objective. The first paragraph of 250.4 indicates that the performance objectives stated in 250.4(A) for grounded systems and in 250.4(B) for ungrounded systems are accomplished by complying with the prescriptive requirements found in the rest of Article 250.

The requirements of 250.4 do not provide a specific rule for the sizing or connection of grounding conductors; rather, it states overall performance considerations for grounding conductors and applies to both grounded and ungrounded systems.

#### (A) Grounded Systems.

**(1) Electrical System Grounding.** Electrical systems that are grounded shall be connected to earth in a manner that will limit the voltage imposed by lightning, line surges, or unintentional contact with higher-voltage lines and that will stabilize the voltage to earth during normal operation.

**Informational Note:** An important consideration for limiting the imposed voltage is the routing of bonding and grounding electrode conductors so that they are not any longer than necessary to complete the connection without disturbing the permanent parts of the installation and so that unnecessary bends and loops are avoided.

**(2) Grounding of Electrical Equipment.** Normally non-current-carrying conductive materials enclosing electrical conductors or equipment, or forming part of such equipment, shall be connected to earth so as to limit the voltage to ground on these materials.

**(3) Bonding of Electrical Equipment.** Normally non-current-carrying conductive materials enclosing electrical conductors or equipment, or forming part of such equipment, shall be connected together and to the electrical supply source in a manner that establishes an effective ground-fault current path.

**(4) Bonding of Electrically Conductive Materials and Other Equipment.** Normally non-current-carrying electrically conductive materials that are likely to become energized shall be connected together and to the electrical supply source in a manner that establishes an effective ground-fault current path.

**(5) Effective Ground-Fault Current Path.** Electrical equipment and wiring and other electrically conductive material likely to become energized shall be installed in a manner that creates a low-impedance circuit facilitating the operation of the overcurrent device or ground detector for high-impedance grounded systems. It shall be capable of safely carrying the maximum ground-fault current likely to

be imposed on it from any point on the wiring system where a ground fault may occur to the electrical supply source. The earth shall not be considered as an effective ground-fault current path.

Section 250.4(A)(5) recognizes that the performance objective for the effective ground-fault current path is not always to facilitate operation of an overcurrent protective device. In the case of a high-impedance grounded system installed in accordance with 250.36, the performance objective is to ensure operation of the required ground detector in order to activate some type of an alarm or other signal indicating the existence of a ground-fault condition.

#### (B) Ungrounded Systems.

**(1) Grounding Electrical Equipment.** Non-current-carrying conductive materials enclosing electrical conductors or equipment, or forming part of such equipment, shall be connected to earth in a manner that will limit the voltage imposed by lightning or unintentional contact with higher-voltage lines and limit the voltage to ground on these materials.

**(2) Bonding of Electrical Equipment.** Non-current-carrying conductive materials enclosing electrical conductors or equipment, or forming part of such equipment, shall be connected together and to the supply system grounded equipment in a manner that creates a low-impedance path for ground-fault current that is capable of carrying the maximum fault current likely to be imposed on it.

**(3) Bonding of Electrically Conductive Materials and Other Equipment.** Electrically conductive materials that are likely to become energized shall be connected together and to the supply system grounded equipment in a manner that creates a low-impedance path for ground-fault current that is capable of carrying the maximum fault current likely to be imposed on it.

**(4) Path for Fault Current.** Electrical equipment, wiring, and other electrically conductive material likely to become energized shall be installed in a manner that creates a low-impedance circuit from any point on the wiring system to the electrical supply source to facilitate the operation of overcurrent devices should a second ground fault from a different phase occur on the wiring system. The earth shall not be considered as an effective fault-current path.

The performance requirements for grounding covered in 250.4(A) and (B) can be categorized into two functions: system grounding and equipment grounding. These two functions are kept separate except at the point of supply, such as at the service equipment or at a separately derived system.

Grounding is the intentional connection of a current-carrying conductor to ground or something that serves in place of ground. In most instances, this connection is made at the supply source, such as a transformer, and at the main service disconnecting means of the premises using the energy. Where a system operates “ungrounded” it does not have an intentionally grounded circuit conductor (*grounded conductor*) but equipment grounding through the use of an *equipment grounding conductor* is required.

There are two basic reasons for connecting electrical systems to ground (grounding):

1. To limit the voltages caused by lightning or by accidental contact of the supply conductors with conductors of higher voltage
2. To stabilize the voltage under normal operating conditions (which maintains the voltage at one level relative to ground, so that any equipment connected to the system will be subject only to that potential difference)

Exhibit 250.1 shows a grounded single-phase, 3-wire service supplied from a utility transformer. Inside the service disconnecting means enclosure, the grounded conductor of the system is intentionally connected to a grounding electrode via the grounding electrode conductor. Bonding the equipment grounding bus to the grounded or neutral bus via the main bonding jumper within the service disconnecting means enclosure provides a ground reference for exposed, non-current-carrying parts of the electrical system and a circuit through the grounded service conductor back to the utility transformer (source of supply) for ground-fault current. At the utility transformer, oftentimes an additional connection from the grounded conductor to a separate grounding electrode is made. It is the bonding of the equipment ground-

ing conductor bus to the neutral bus, and not the connections to earth, that facilitates the operation of overcurrent protective devices or relays underground-fault conditions.

## 250.6 Objectionable Current

### (A) Arrangement to Prevent Objectionable Current.

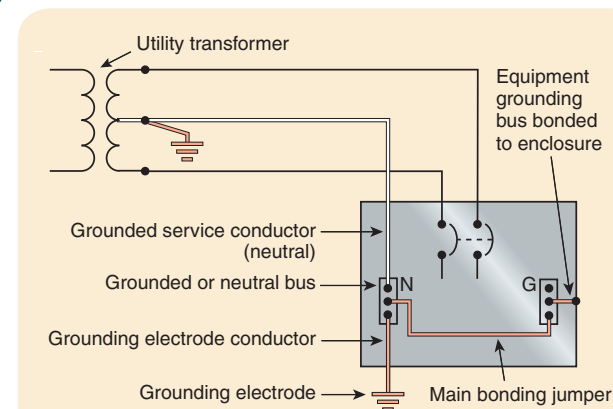

The grounding of electrical systems, circuit conductors, surge arresters, surge-protective devices, and conductive normally non-current-carrying metal parts of equipment shall be installed and arranged in a manner that will prevent objectionable current.

**(B) Alterations to Stop Objectionable Current.** If the use of multiple grounding connections results in objectionable current, one or more of the following alterations shall be permitted to be made, provided that the requirements of 250.4(A)(5) or (B)(4) are met:

- (1) Discontinue one or more but not all of such grounding connections.
- (2) Change the locations of the grounding connections.
- (3) Interrupt the continuity of the conductor or conductive path causing the objectionable current.
- (4) Take other suitable remedial and approved action.

An increase in the use of electronic controls and computer equipment, which are sensitive to stray currents, has caused installation designers to look for ways to isolate electronic equipment from the effects of such stray circulating currents. Circulating currents on equipment grounding conductors, metal raceways, and building steel develop potential differences between ground and the neutral of electronic equipment.

A solution often recommended by inexperienced individuals is to isolate the electronic equipment from all other power equipment by disconnecting it from the power equipment ground. In this corrective action, the equipment grounding means is removed or nonmetallic spacers are installed in the metallic raceway system contrary to fundamental safety grounding principles covered in the requirements of Article 250. The electronic equipment is then grounded to an earth ground isolated from the common power system ground. Isolating equipment in this manner creates a potential difference that is a shock hazard. The error is compounded because such isolation does not establish a low-impedance ground-fault return path to the power source, which is necessary to actuate the overcurrent protection device. Section 250.6(B) is not intended to allow disconnection of all power grounding connections to the electronic equipment. See the commentary following 250.6(D).

**EXHIBIT 250.1** Grounding and bonding arrangement for a single-phase, 3-wire service.

**(C) Temporary Currents Not Classified as Objectionable Currents.** Temporary currents resulting from abnormal conditions, such as ground faults, shall not be classified as objectionable current for the purposes specified in 250.6(A) and (B).

**(D) Limitations to Permissible Alterations.** The provisions of this section shall not be considered as permitting electronic equipment from being operated on ac systems or branch circuits that are not connected to an equipment grounding conductor as required by this article. Currents that introduce noise or data errors in electronic equipment shall not be considered the objectionable currents addressed in this section.

Section 250.6(D) indicates that currents that result in noise or data errors in electronic equipment are not considered to be the objectionable currents referred to in 250.6, which limits the alterations permitted by 250.6(C). See 250.96(B) and 250.146(D) for requirements that provide safe bonding and grounding methods to minimize noise and data errors.

**(E) Isolation of Objectionable Direct-Current Ground Currents.** Where isolation of objectionable dc ground currents from cathodic protection systems is required, a listed ac coupling/dc isolating device shall be permitted in the equipment grounding conductor path to provide an effective return path for ac ground-fault current while blocking dc current.

Because the dc ground current on grounding conductors as a result of a cathodic protection system may be considered objectionable, 250.6(E) allows the use of a listed ac coupling/dc isolating device. This device blocks the dc current on grounding and bonding conductors and allows the ground-fault return path to function properly. To be listed for this function, these devices are evaluated by the product testing organizations for proper performance under ground-fault conditions.

Where cathodic protection for the piping system is provided, the required grounding and bonding connections associated with metal piping systems is conducive to dc current being imposed on grounding and bonding conductors.

## 250.8 Connection of Grounding and Bonding Equipment

**(A) Permitted Methods.** Equipment grounding conductors, grounding electrode conductors, and bonding jumpers shall be connected by one of the following means:

- (1) Listed pressure connectors
- (2) Terminal bars
- (3) Pressure connectors listed as grounding and bonding equipment
- (4) Exothermic welding process
- (5) Machine screw-type fasteners that engage not less than two threads or are secured with a nut
- (6) Thread-forming machine screws that engage not less than two threads in the enclosure
- (7) Connections that are part of a listed assembly
- (8) Other listed means

Section 250.8 recognizes the use of machine screws and thread-forming machine screws as methods to connect grounding and bonding conductors. By specifically identifying machine screws and thread-forming machine screws as acceptable connection methods, this section indicates that no other type of screw, such as a sheet metal screw or a wood screw, can be used for the connection of grounding and bonding conductors or terminals. Listed pressure connectors, such as twist-on wire connectors that are not specifically listed for grounding, as well as those that are specifically listed as grounding and bonding equipment, can be used for connection of grounding and bonding conductors. The use of listed pressure connectors other than those that are green in color is permitted for the connection of grounding and bonding conductors. Exhibits 250.2 and 250.3 illustrate two acceptable methods of attaching an equipment bonding jumper to a grounded metal box.

**EXHIBIT 250.2** Use of a grounding screw to attach equipment bonding jumper to a metal box.

**(B) Methods Not Permitted.** Connection devices or fittings that depend solely on solder shall not be used.

**EXHIBIT 250.3** Use of a listed grounding clip to attach a grounding conductor to a metal box.

## 250.10 Protection of Ground Clamps and Fittings

Ground clamps or other fittings shall be approved for general use without protection or shall be protected from physical damage as indicated in (1) or (2) as follows:

- (1) In installations where they are not likely to be damaged
- (2) Where enclosed in metal, wood, or equivalent protective covering

## 250.12 Clean Surfaces

Nonconductive coatings (such as paint, lacquer, and enamel) on equipment to be grounded shall be removed from threads and other contact surfaces to ensure good electrical continuity or be connected by means of fittings designed so as to make such removal unnecessary.

## II. System Grounding

### 250.20 Alternating-Current Systems to Be Grounded

Alternating-current systems shall be grounded as provided for in 250.20(A), (B), (C), or (D). Other systems shall be permitted to be grounded. If such systems are grounded, they shall comply with the applicable provisions of this article.

**Informational Note:** An example of a system permitted to be grounded is a corner-grounded delta transformer connection. See 250.26(4) for conductor to be grounded.

**(A) Alternating-Current Systems of Less Than 50 Volts.** Alternating-current systems of less than 50 volts shall be grounded under any of the following conditions:

- (1) Where supplied by transformers, if the transformer supply system exceeds 150 volts to ground

- (2) Where supplied by transformers, if the transformer supply system is ungrounded
- (3) Where installed outside as overhead conductors

**(B) Alternating-Current Systems of 50 Volts to 1000 Volts.** Alternating-current systems of 50 volts to less than 1000 volts that supply premises wiring and premises wiring systems shall be grounded under any of the following conditions:

- (1) Where the system can be grounded so that the maximum voltage to ground on the ungrounded conductors does not exceed 150 volts

The grounding requirements of 250.20(B)(1) as applied to a 120-volt, single-phase, 2-wire system and to a 120/240-volt, single-phase, 3-wire system are shown in Exhibit 250.4. The selection of which conductor to be grounded is covered in 250.26.

120-V, single-phase, 2-wire system

120/240-V, single-phase, 3-wire system

**EXHIBIT 250.4** Typical systems required to be grounded in accordance with 250.20(B)(1). The conductor to be grounded is specified in 250.26.

- (2) Where the system is 3-phase, 4-wire, wye connected in which the neutral conductor is used as a circuit conductor
- (3) Where the system is 3-phase, 4-wire, delta connected in which the midpoint of one phase winding is used as a circuit conductor

The top figure in Exhibit 250.5 illustrates a 3-phase, 4-wire, wye connected system covered by 250.20(B)(2). Because this system supplies line-to-neutral connected loads in addition to line-to-line connected loads, the neutral conductor is required to be grounded. The bottom figure shows a 3-phase, 4-wire delta system covered by 250.20(B)(3). A connection is made at the midpoint of one phase to enable line-to-neutral loads to be supplied. The same voltage is developed between this grounded conductor and the two phase conductors connected at either end of the winding that is midpoint grounded. The voltage between the third phase conductor and the grounded conductor is higher, and there are other requirements in the *Code* covering the arrangement and identification of the “high-leg” in this system. For systems that are required to be grounded by 250.20(B)(1), (2), or (3), 250.26 contains the requirements covering which conductor is to be grounded.

208Y/120-V, 3-phase, 4-wire wye system

120/240-V, 3-phase, 4-wire delta system

**EXHIBIT 250.5** Typical systems required to be grounded by 250.20(B)(2) and (B)(3). The conductor to be grounded is in accordance with 250.26.

**(C) Alternating-Current Systems of 1 kV and Over.** Alternating-current systems supplying mobile or portable equipment shall be grounded as specified in 250.188. Where supplying other than mobile or portable equipment, such systems shall be permitted to be grounded.

**(D) Impedance Grounded Neutral Systems.** Impedance grounded neutral systems shall be grounded in accordance with 250.36 or 250.186.

## 250.21 Alternating-Current Systems of 50 Volts to Less Than 1000 Volts Not Required to Be Grounded

**(A) General.** The following ac systems of 50 volts to less than 1000 volts shall be permitted to be grounded but shall not be required to be grounded:

- (1) Electrical systems used exclusively to supply industrial electric furnaces for melting, refining, tempering, and the like
- (2) Separately derived systems used exclusively for rectifiers that supply only adjustable-speed industrial drives
- (3) Separately derived systems supplied by transformers that have a primary voltage rating less than 1000 volts, provided that all the following conditions are met:
  - a. The system is used exclusively for control circuits.
  - b. The conditions of maintenance and supervision ensure that only qualified persons service the installation.
  - c. Continuity of control power is required.
- (4) Other systems that are not required to be grounded in accordance with the requirements of 250.20(B)

Ungrounded systems are simply systems without an intentionally grounded conductor that is used in normal circuit operation. Systems that normally operate as grounded systems such as 120/240-volt, single-phase, 3-wire; 208Y/120-volt, 3-phase, 4-wire; and 480Y/277-volt, 3-phase, 4-wire systems can be operated as ungrounded systems where specifically permitted by the *Code*. The fact that a system operates without a grounded conductor does not exempt that system from complying with all of the applicable requirements in Article 250 for establishing a grounding electrode system and for equipment grounding. These protective features are required for grounded and ungrounded electrical distribution systems.

Ungrounded electrical systems are permitted for the specific functions described in 250.21(A)(1), (2), and (3) and for general power distribution systems in accordance with 250.21(A)(4). Delta-connected, 3-phase, 3-wire, 240-volt and 480-volt systems are examples of common electrical distribution systems that are permitted but are not required to have a circuit conductor that is intentionally grounded. The operational advantage in using an ungrounded electrical system is continuity of operation, which in some processes might create a safer condition than would be achieved by the automatic and unplanned opening of the supply circuit. The disadvantage of operating systems

ungrounded is increased susceptibility to high transient voltages that can hasten insulation deterioration. As stated in 250.4(A)(1), limiting voltage impressed on the system due to lightning or line surges is a primary function of system grounding. In some specific applications, it may be desirable to not establish a voltage to ground, but throughout the history of the *Code*, the consensus opinion has been that for general applications, grounded systems provide a higher level of safety.

Unlike solidly grounded systems, in which the first line-to-ground fault causes the overcurrent protective device to automatically open the circuit, the same line-to-ground fault in an ungrounded system does not result in the operation of the overcurrent device — it simply results in the faulted circuit conductor becoming a grounded conductor until a repair of the damaged conductor insulation can be performed. However, this latent ground-fault condition will remain undetected unless ground detectors are installed in the ungrounded system or until another insulation failure on a different ungrounded conductor results in a line-to-line-to-ground fault, with the potential for more extensive damage to electrical equipment.

**(B) Ground Detectors.** Ground detectors shall be installed in accordance with 250.21(B)(1) and (B)(2).

- (1) Ungrounded alternating current systems as permitted in 250.21(A)(1) through (A)(4) operating at not less than 120 volts and not exceeding 1000 volts shall have ground detectors installed on the system.
- (2) The ground detection sensing equipment shall be connected as close as practicable to where the system receives its supply.

Ground detectors are used to provide a visual indication, an audible signal, or both, to alert system operators and maintainers of a ground-fault condition in the electrical system. With notification of the ground-fault condition, rather than automatic interruption of the circuit, the operators of the process supplied by the ungrounded system can then take the necessary steps to effect an orderly shutdown, determine where the ground fault is located in the system, and can safely perform the necessary repair.

**(C) Marking.** Ungrounded systems shall be legibly marked “Ungrounded System” at the source or first disconnecting means of the system. The marking shall be of sufficient durability to withstand the environment involved.

Ungrounded electrical systems, as permitted in 250.21(A), are required to be provided with ground detectors, and the

source or first system disconnecting means is required to be marked to indicate this condition of operation. Similar to other requirements that specify marking to provide a safety warning, the permanency of the marking is critical to ensure that the safety message of the marking is conveyed to those who may install or work on equipment supplied by this system after its initial installation. In the 2002 and previous editions of the *Code*, the installation of ground detectors was required only for some very specific applications of ungrounded systems (and in impedance grounded neutral systems), but only a recommendation was given that they be installed on all ungrounded electrical systems. For further information on what is considered to be the voltage to ground in an ungrounded system, see the definition of *voltage to ground* in Article 100.

## 250.22 Circuits Not to Be Grounded

The following circuits shall not be grounded:

- (1) Circuits for electric cranes operating over combustible fibers in Class III locations, as provided in 503.155
- (2) Circuits in health care facilities as provided in 517.61 and 517.160
- (3) Circuits for equipment within electrolytic cell working zone as provided in Article 668
- (4) Secondary circuits of lighting systems as provided in 411.5(A)
- (5) Secondary circuits of lighting systems as provided in 680.23(A)(2).

## 250.24 Grounding Service-Supplied Alternating-Current Systems

**(A) System Grounding Connections.** A premises wiring system supplied by a grounded ac service shall have a grounding electrode conductor connected to the grounded service conductor, at each service, in accordance with 250.24(A)(1) through (A)(5).

The power for ac premises wiring systems is either separately derived, in accordance with 250.30, or supplied by the service. See the definition of *service* in Article 100. Section 250.30 covers grounding requirements for separately derived ac systems, and 250.24(A)(1) through (5) covers system grounding requirements for premises supplied by an ac service. The grounded conductor of an ac service is connected to a grounding electrode system to limit the voltage to ground imposed on the system by lightning, line surges, and (unintentional) high-voltage crossovers. Another reason for requiring this connection is to stabilize the voltage to ground during normal operation, including short circuits. These performance requirements are stated in 250.4(A) and 250.4(B).

**(1) General.** The grounding electrode conductor connection shall be made at any accessible point from the load end of the service drop or service lateral to and including the terminal or bus to which the grounded service conductor is connected at the service disconnecting means.

Informational Note: See definitions of *Service Drop* and *Service Lateral* in Article 100.

According to 250.24(A)(1), the actual connection of the grounded service conductor to the grounded electrode conductor is permitted to be made at various locations. Allowing various locations for the connection to be made continues to meet the overall objectives for grounding while allowing the installer a variety of practical solutions. Exhibit 250.6 illustrates three possible connection point locations where the grounding electrode conductor is permitted to be connected to the grounded service conductor. Determination of whether a point of connection is *accessible* has to be determined by the authority having jurisdiction based on local conditions such as locked meter socket enclosures.

**EXHIBIT 250.6** Three locations where 250.24(A)(1) permits the grounding electrode conductor to be connected to the ground service conductor.

**(2) Outdoor Transformer.** Where the transformer supplying the service is located outside the building, at least one additional grounding connection shall be made from the grounded service conductor to a grounding electrode, either at the transformer or elsewhere outside the building.

*Exception:* The additional grounding electrode conductor connection shall not be made on high-impedance grounded neutral systems. The system shall meet the requirements of 250.36.

A grounding electrode conductor connected to the grounded service conductor at an outdoor transformer is one example of how the requirement of 250.24(A)(2) can be met. Outdoor installations are susceptible to lightning activity as well as accidental primary-to-secondary crossovers, and this requirement for a connection located outside of a building helps mitigate the effects of these influences on the interior portion of the premises wiring system. Exhibit 250.7 illustrates two grounding electrode connections, one at the service equipment installed inside the building and one installed at the transformer, located outside of the building as required by 250.24(A)(2).

**EXHIBIT 250.7** Grounding connection to the grounded conductor at the transformer as required by 250.24(A)(2).

**(3) Dual-Fed Services.** For services that are dual fed (double ended) in a common enclosure or grouped together in separate enclosures and employing a secondary tie, a single grounding electrode conductor connection to the tie point of the grounded conductor(s) from each power source shall be permitted.

**(4) Main Bonding Jumper as Wire or Busbar.** Where the main bonding jumper specified in 250.28 is a wire or busbar and is installed from the grounded conductor terminal bar or bus to the equipment grounding terminal bar or bus in the service equipment, the grounding electrode conductor shall be permitted to be connected to the equipment grounding terminal, bar, or bus to which the main bonding jumper is connected.

**(5) Load-Side Grounding Connections.** A grounded conductor shall not be connected to normally non-current-carrying metal parts of equipment, to equipment grounding

conductor(s), or be reconnected to ground on the load side of the service disconnecting means except as otherwise permitted in this article.

Informational Note: See 250.30 for separately derived systems, 250.32 for connections at separate buildings or structures, and 250.142 for use of the grounded circuit conductor for grounding equipment.

Section 250.24(A)(5) prohibits re-grounding of the grounded conductor on the load side of the service disconnecting means. This requirement correlates with the requirement of 250.142(B), which is a general prohibition on the use of the grounded conductor for grounding equipment. This requirement prevents parallel paths for neutral current on the load side of the service disconnecting means. Such parallel paths could include metal raceways, metal piping systems, metal ductwork, structural steel, and similar continuous metal paths that are not intended to be a normal current-carrying conductor.

**(B) Main Bonding Jumper.** For a grounded system, an unspliced main bonding jumper shall be used to connect the equipment grounding conductor(s) and the service-disconnect enclosure to the grounded conductor within the enclosure for each service disconnect in accordance with 250.28.

Where the service equipment of a grounded system consists of multiple disconnecting means, a main bonding jumper for each separate service disconnecting means is required to connect the grounded service conductor, the equipment grounding conductor, and the service equipment enclosure. The size of the main bonding jumper in each enclosure is selected from Table 250.66 based on the size of the ungrounded service conductors, or it is calculated in accordance with 250.28(D)(1). See Exhibits 250.8 and 250.9, which accompany the commentary following 250.24(C), Exception.

*Exception No. 1: Where more than one service disconnecting means is located in an assembly listed for use as service equipment, an unspliced main bonding jumper shall bond the grounded conductor(s) to the assembly enclosure.*

Where multiple service disconnecting means are part of an assembly listed as service equipment, all grounded service conductors are required to be run to and bonded to the assembly. However, only one section of the assembly is required to have the main bonding jumper connection. See Exhibit 250.10, which accompanies the commentary following 250.28(D).

*Exception No. 2: Impedance grounded neutral systems shall be permitted to be connected as provided in 250.36 and 250.186.*

**(C) Grounded Conductor Brought to Service Equipment.** Where an ac system operating at less than 1000 volts is grounded at any point, the grounded conductor(s) shall be routed with the ungrounded conductors to each service disconnecting means and shall be connected to each disconnecting means grounded conductor(s) terminal or bus. A main bonding jumper shall connect the grounded conductor(s) to each service disconnecting means enclosure. The grounded conductor(s) shall be installed in accordance with 250.24(C)(1) through (C)(4).

*Exception: Where two or more service disconnecting means are located in a single assembly listed for use as service equipment, it shall be permitted to connect the grounded conductor(s) to the assembly common grounded conductor(s) terminal or bus. The assembly shall include a main bonding jumper for connecting the grounded conductor(s) to the assembly enclosure.*

If the utility service supplying the premises wiring system is grounded, the grounded conductor, whether or not it is used to supply a load, must be run to the service equipment, be bonded to the equipment, and be connected to a grounding electrode system. Exhibit 250.8 shows an example of the main rule in 250.24(C), which requires the grounded service conductor to be installed and bonded to each service disconnecting means enclosure. On the line side of the service disconnecting means, the grounded conductor is used to complete the ground-fault current path between the service equipment and the utility source. The grounded service conductor's other function, as a circuit conductor for line-to-neutral connected loads, is covered in 200.3 and 220.61. The exception to 250.24(C) permits a single connection of the grounded service conductor to a listed service assembly (such as a switchboard) that contains more than one service disconnecting means, as shown in Exhibit 250.9.

**(1) Sizing for a Single Raceway.** The grounded conductor shall not be smaller than the required grounding electrode conductor specified in Table 250.66 but shall not be required to be larger than the largest ungrounded service-entrance conductor(s). In addition, for sets of ungrounded service-entrance conductors larger than 1100 kcmil copper or 1750 kcmil aluminum, the grounded conductor shall not be smaller than 12½ percent of the circular mil area of the largest set of service-entrance ungrounded conductor(s).

**(2) Parallel Conductors in Two or More Raceways.** If the ungrounded service-entrance conductors are installed in par-

**EXHIBIT 250.8** A grounded system in which the grounded service conductor is bonded to the enclosure supplying 3-phase, 4-wire service loads and to the enclosure supplying 3-phase, 3-wire loads.

**EXHIBIT 250.9** One connection of the grounded service conductor to a listed service assembly containing multiple service disconnecting means, in accordance with 250.24(C), Exception.

allel in two or more raceways, the grounded conductor shall also be installed in parallel. The size of the grounded conductor in each raceway shall be based on the total circular mil area of the parallel ungrounded conductors in the raceway, as indicated in 250.24(C)(1), but not smaller than 1/0 AWG.

Informational Note: See 310.10(H) for grounded conductors connected in parallel.

For a multiple raceway or cable service installation, the minimum size for the grounded conductor in each raceway or cable where conductors are in parallel cannot be less than

1/0 AWG. Although the cumulative size of the parallel grounded conductors may be larger than is required by 250.24(C)(1), the minimum 1/0 AWG per raceway or cable correlates with the requirements for parallel conductors contained in 310.10(H).

**(3) Delta-Connected Service.** The grounded conductor of a 3-phase, 3-wire delta service shall have an ampacity not less than that of the ungrounded conductors.

**(4) High Impedance.** The grounded conductor on a high-impedance grounded neutral system shall be grounded in accordance with 250.36.

**(D) Grounding Electrode Conductor.** A grounding electrode conductor shall be used to connect the equipment grounding conductors, the service-equipment enclosures, and, where the system is grounded, the grounded service conductor to the grounding electrode(s) required by Part III of this article. This conductor shall be sized in accordance with 250.66.

High-impedance grounded neutral system connections shall be made as covered in 250.36.

Informational Note: See 250.24(A) for ac system grounding connections.

**(E) Ungrounded System Grounding Connections.** A premises wiring system that is supplied by an ac service that is ungrounded shall have, at each service, a grounding electrode conductor connected to the grounding electrode(s) required by Part III of this article. The grounding electrode conductor shall be connected to a metal enclosure of the service conductors at any accessible point from the load end of the service drop or service lateral to the service disconnecting means.

## 250.26 Conductor to Be Grounded — Alternating-Current Systems

For ac premises wiring systems, the conductor to be grounded shall be as specified in the following:

- (1) Single-phase, 2-wire — one conductor
- (2) Single-phase, 3-wire — the neutral conductor
- (3) Multiphase systems having one wire common to all phases — the common conductor
- (4) Multiphase systems where one phase is grounded — one phase conductor
- (5) Multiphase systems in which one phase is used as in (2) — the neutral conductor

Section 250.26 works in conjunction with 250.20(B). Once the requirements of 250.20(B) establish that a system is

required to be grounded, the requirements of 250.26 identify the conductor in the system that is required to be grounded. In addition to covering systems where it is mandatory to ground the system, this requirement also identifies which conductor is to be grounded in systems that are permitted to be grounded, such as a corner-grounded delta system.

### 250.28 Main Bonding Jumper and System Bonding Jumper

For a grounded system, main bonding jumpers and system bonding jumpers shall be installed as follows:

The system bonding jumper required in 250.28 performs the same electrical function as the main bonding jumper in a grounded ac system by connecting the equipment grounding conductor(s) to the grounded circuit conductor either at the source of a separately derived system or at the first disconnecting means supplied by the source. The term *system bonding jumper* is used to distinguish it from the main bonding jumper, which is installed in service equipment. See the commentary following the definition of *bonding jumper, system* in Article 100.

**(A) Material.** Main bonding jumpers and system bonding jumpers shall be of copper or other corrosion-resistant material. A main bonding jumper and a system bonding jumper shall be a wire, bus, screw, or similar suitable conductor.

**(B) Construction.** Where a main bonding jumper or a system bonding jumper is a screw only, the screw shall be identified with a green finish that shall be visible with the screw installed.

The requirement in 250.28(B) specifies that where a screw is used for the main or system bonding jumper, the screw must have a green color that is visible when it is installed. This identification requirement makes it possible to readily distinguish the bonding jumper screw from other screws in the grounded conductor terminal bar, to ensure that the required bonding connection has been made.

**(C) Attachment.** Main bonding jumpers and system bonding jumpers shall be connected in the manner specified by the applicable provisions of 250.8.

**(D) Size.** Main bonding jumpers and system bonding jumpers shall be sized in accordance with 250.28(D)(1) through (D)(3).

**(1) General.** Main bonding jumpers and system bonding jumpers shall not be smaller than the sizes shown in Table

250.66. Where the supply conductors are larger than 1100 kcmil copper or 1750 kcmil aluminum, the bonding jumper shall have an area that is not less than 12½ percent of the area of the largest phase conductor except that, where the phase conductors and the bonding jumper are of different materials (copper or aluminum), the minimum size of the bonding jumper shall be based on the assumed use of phase conductors of the same material as the bonding jumper and with an ampacity equivalent to that of the installed phase conductors.

In a grounded system, the primary function of the main bonding jumper and of the system bonding jumper is to create the link for ground-fault current between the equipment grounding conductors and the grounded conductor. Table 250.66, Grounding Electrode Conductor for Alternating-Current Systems, has a number of functions in Article 250 in addition to its use for sizing the grounding electrode conductor. It is used in this section to establish the minimum size of main and system bonding jumpers where the ungrounded conductors do not exceed 1100-kcmil copper or 1750-kcmil aluminum. Unlike the function of the grounding electrode conductor, which carries current to the ground (via connection to a grounding electrode), the main and system bonding jumpers are placed directly in the supply-side ground-fault current return path. Therefore, where the largest ungrounded supply conductor exceeds the parameters of Table 250.66, it is necessary to maintain a proportional relationship between the ungrounded conductor and the main or system bonding jumper.

Where large capacity services or separately derived systems are installed, it is likely that the main or system bonding jumper will be larger than the grounding electrode conductor. Section 250.28(D)(1) requires that where the service-entrance conductors are larger than 1100-kcmil copper or 1750-kcmil aluminum, the bonding jumper must have a cross-sectional area of not less than 12½ percent of the cross-sectional area of the largest phase conductor or largest phase conductor set. In equipment such as panelboards or switchboards that are listed for use as service equipment, the manufacturer provides a bonding jumper that can be installed as the main or system bonding jumper. Thus, it is not necessary to duplicate this bonding jumper with another one sized in accordance with 250.28(D)(1).

**(2) Main Bonding Jumper for Service with More Than One Enclosure.** Where a service consists of more than a single enclosure as permitted in 230.71(A), the main bonding jumper for each enclosure shall be sized in accordance with 250.28(D)(1) based on the largest ungrounded service conductor serving that enclosure.

Where a service consists of more than one disconnecting means in separate enclosures, each line-side service equip-

ment enclosure is treated separately, as depicted in Exhibit 250.10. The main bonding jumper in the left enclosure is a 4 AWG copper conductor. Based on the 3/0 AWG ungrounded service conductors supplying the 200-ampere circuit breaker and Table 250.66, the minimum-size main bonding jumper for this service equipment enclosure is 4 AWG copper. Similarly, the 1/0 AWG main bonding jumper for the enclosure on the right is derived from Table 250.66 using the 500-kcmil ungrounded service conductors.

In addition to the main bonding jumpers for the two disconnecting means enclosures, other conductors shown in Exhibit 250.10 are sized using Table 250.66. First, the grounding electrode conductor at 2/0 AWG is full-sized based on Table 250.66 using the 750-kcmil ungrounded service conductor as the basis for selection. Note that in some conditions the grounding electrode conductor is permitted to be sized smaller than what is required in the table; see 250.66.

**EXHIBIT 250.10** An example of the bonding requirements for service equipment.

Next, the grounded conductor run to each enclosure in accordance with 250.24(B) is sized using Table 250.66 as the minimum size permitted. For the grounded conductor, the reference to Table 250.66 is found in 250.24(C)(1). For each enclosure, the minimum size grounded conductor is established based on the largest ungrounded conductor serving that enclosure. The grounded conductor is also subject to the requirements of 220.61 covering the conductor's capacity for unbalanced load, which could result in having to increase the size to larger than what was determined from Table 250.66.

Finally, supply-side bonding jumpers are used for the three bonding metal conduits containing service conductors and the metal wireway located above the two service equipment enclosures. These bonding jumpers are also sized from Table 250.66 via a reference from 250.102(C). The bonding jumpers for the raceways are sized based on the ungrounded conductors contained in each metal service raceway.

For the metal conduit entering the top of the wireway and for the wireway itself shown in Exhibit 250.10, the bonding jumper is sized from Table 250.66 based on the 750-kcmil main service-entrance conductors and cannot be less than a 2/0 AWG copper conductor. The service-entrance conductors to the enclosures are 3/0 AWG and 500-kcmil copper, based on the loads supplied from each enclosure. The supply-side bonding jumpers for the short nipples are sized based on the size of the phase conductors supplying each disconnecting means. In this case, the metal raceway nipples containing the 3/0 AWG and 500-kcmil ungrounded service conductors require minimum 4 AWG and 1/0 AWG copper supply-side bonding jumpers, respectively.

#### Application Example

A service is supplied by four 500-kcmil conductors in parallel for each phase; the minimum cross-sectional area of the bonding jumper is calculated as follows:  $4 \times 500 \text{ kcmil} = 2000 \text{ kcmil}$ . Therefore, the main or system bonding jumper cannot be less than 12½ percent of 2000 kcmil, which results in a 250-kcmil copper conductor. The copper grounding electrode conductor for this set of conductors, based on Table 250.66, is not required to be larger than 3/0 AWG.

**(3) Separately Derived System with More Than One Enclosure.** Where a separately derived system supplies more than a single enclosure, the system bonding jumper for each enclosure shall be sized in accordance with 250.28(D)(1) based on the largest ungrounded feeder conductor serving that enclosure, or a single system bonding jumper shall be installed at the source and sized in accordance with 250.28(D)(1) based on the equivalent size of the largest supply conductor determined by the largest sum of the areas of the corresponding conductors of each set.

Section 250.28(D)(3) provides two options for sizing the system bonding jumper for a separately derived system that supplies multiple enclosures. Option 1 is to provide a system bonding jumper at each enclosure based on the size of the ungrounded conductors serving that enclosure. Option 2 is to provide a single system bonding jumper at the source. To determine the size of the system bonding jumper, all of the ungrounded conductors serving the multiple enclosures must be evaluated and the phase that yields the largest

collective circular mil area is the basis for sizing the system bonding jumper.

#### Calculation Example 1

A 225-kVA transformer supplies three, 3-phase, 208Y/120-volt secondary feeders that terminate in panelboards with 200-ampere main breakers. The ungrounded conductors for all three phases are 3/0 AWG, copper with THHW insulation. A system bonding jumper is installed at each of the panelboards. Determine the size of the system bonding jumpers at each enclosure using Option 1.

#### Solution

Size of largest ungrounded conductor supplying individual panelboard:

3/0 AWG copper

System bonding jumper (from Table 250.66):

3/0 AWG copper ungrounded conductors → 4 AWG copper  
or 2 AWG aluminum system bonding jumper

Depending on how the transformer and the panelboards are arranged to prevent parallel neutral current paths on raceways and enclosures, the system bonding jumper may be internal to the panelboard using the manufacturer-supplied equipment or it may be installed in the transformer enclosure so that it connects any supply-side bonding jumpers to the neutral terminal (XO) of the transformer.

#### Calculation Example 2

The same electrical equipment arrangement as in the previous example applies. In this case, however, the system bonding jumper is installed at the transformer and connects the transformer neutral terminal (XO) to individual supply-side bonding jumpers that are installed between the panelboard equipment grounding conductor terminals and a terminal bus attached to the transformer enclosure. Determine the size of the system bonding jumper using Option 2.

#### Solution

STEP 1. Size the individual supply-side bonding jumpers from each of the panelboard equipment grounding terminals to the terminal bus in the transformer.

From Table 250.66:

3/0 AWG copper ungrounded conductors → 4 AWG copper  
or 2 AWG aluminum system bonding jumper

STEP 2. Size the system bonding jumper from the terminal bus in the transformer to the transformer neutral terminal (XO). There are three secondary feeder circuits with 3/0 AWG ungrounded conductors for all phases. Find the cumulative circular mil area of one phase.

From Chapter 9, Table 8:

3/0 AWG = 167,800 circular mils

167,800 circular mils × 3 (number of sets of secondary conductors) = 503,400 circular mils

From Table 250.66:

503,400 circular mils copper ungrounded conductors →  
1/0 AWG copper

or 3/0 AWG aluminum system bonding jumper

### 250.30 Grounding Separately Derived Alternating-Current Systems

In addition to complying with 250.30(A) for grounded systems, or as provided in 250.30(B) for ungrounded systems, separately derived systems shall comply with 250.20, 250.21, 250.22, and 250.26.

Informational Note No. 1: An alternate ac power source, such as an on-site generator, is not a separately derived system if the grounded conductor is solidly interconnected to a service-supplied system grounded conductor. An example of such a situation is where alternate source transfer equipment does not include a switching action in the grounded conductor and allows it to remain solidly connected to the service-supplied grounded conductor when the alternate source is operational and supplying the load served.

Informational Note No. 2: See 445.13 for the minimum size of conductors that carry fault current.

Exhibits 250.11 and 250.12 depict a 208Y/120-volt, 3-phase, 4-wire electrical service supplying a service disconnecting means to a building. A feeder is installed from the service equipment to the normal power terminals of a transfer switch. The emergency or alternate power terminals of the transfer switch are supplied by a feeder that is supplied by a generator with a 208Y/120-volt, 3-phase output. Emergency, legally required standby, and/or optional standby loads are supplied from the load terminals of the transfer switch in accordance with the applicable requirements of Articles 700, 701, and 702.

In Exhibit 250.11, the neutral conductor from the generator to the load is not disconnected by the transfer switch. The system has a direct electrical connection between the normal grounded system conductor (neutral) and the generator neutral through the neutral bus in the transfer switch, thereby grounding the generator neutral. Because the generator is grounded by connection to the normal system ground, it is not a separately derived system and there are no requirements for grounding the neutral at the generator (see Informational Note No. 1 to 250.30). The conductor installed between the equipment grounding terminal of the transfer

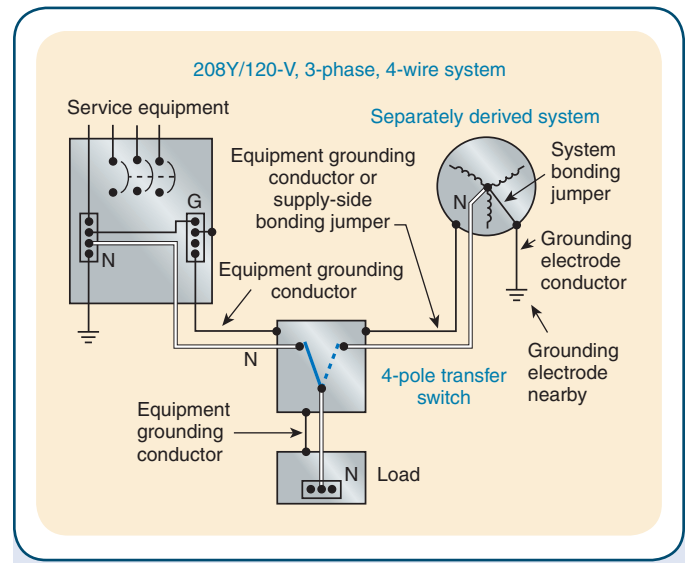

**EXHIBIT 250.11** A 208Y/120-volt, 3-phase, 4-wire system that has a direct electrical connection of the grounded circuit conductor (neutral) to the generator and is therefore not considered a separately derived system.

switch and the generator frame/equipment grounding terminal is either an *equipment grounding conductor* or a *supply-side bonding jumper*, depending on where the first overcurrent device in the generator feeder circuit is located. See 250.35(B) for the requirement covering generators supplying systems that are not separately derived.

In Exhibit 250.12, the grounded conductor (neutral) is connected to the switching contacts of a 4-pole transfer switch. Therefore, the generator system does not have a direct electrical connection to the other supply system grounded conductor (neutral), and the system supplied by the generator is considered separately derived. This separately derived system (3-phase, 4-wire, wye-connected system that supplies line-to-neutral loads) is required to be grounded in accordance with 250.20(B). The methods for grounding the system are specified in 250.30(A).

Section 250.30(A)(1) requires separately derived systems to have a system bonding jumper connected between the generator frame and the grounded circuit conductor (neutral). The grounding electrode conductor from the generator is required to be connected to a grounding electrode. This conductor and the grounding electrode are to be located as close to the generator as practicable, according to 250.30(A)(4). However, because the generator feeder is supplying a building that is also supplied by an ac service, 250.58 requires both supply systems to be connected to the same grounding electrode system. As is the case with the generator supplying the system that is not separately derived, the conductor installed between the equipment

**EXHIBIT 250.12** A 208Y/120-volt, 3-phase, 4-wire system that does not have a direct electrical connection of the grounded circuit conductor (neutral) to the generator and is therefore considered a separately derived system.

grounding terminal of the transfer switch and the generator frame/equipment grounding terminal is either an *equipment grounding conductor* or a *supply-side bonding jumper*, depending on where the first overcurrent device in the generator feeder circuit is located.

**(A) Grounded Systems.** A separately derived ac system that is grounded shall comply with 250.30(A)(1) through (A)(8). Except as otherwise permitted in this article, a grounded conductor shall not be connected to normally non-current-carrying metal parts of equipment, **be connected to equipment grounding conductors**, or be reconnected to ground on the load side of the **system bonding jumper**.

**Informational Note:** See 250.32 for connections at separate buildings or structures, and 250.142 for use of the grounded circuit conductor for grounding equipment.

**Exception:** *Impedance grounded neutral system grounding connections shall be made as specified in 250.36 or 250.186, as applicable.*

Because they have no direct electrical connection, including a solidly connected grounded circuit conductor, to supply conductors originating in another system, it is necessary to establish grounding and bonding connections for each separately derived system. A common installation where the requirements in 250.30(A) are applied is a transformer

installed as part of the premises wiring system. For example, if the service voltage is 480Y/277 volts and there are also loads in the building or structure that operate at 120 volts, it is common for a transformer to be used to develop a separate 208Y/120-volt system for lighting and appliance loads.

**(1) System Bonding Jumper.** An unspliced system bonding jumper shall comply with 250.28(A) through (D). This connection shall be made at any single point on the separately derived system from the source to the first system disconnecting means or overcurrent device, or it shall be made at the source of a separately derived system that has no disconnecting means or overcurrent devices, in accordance with 250.30(A)(1)(a) or (b). The system bonding jumper shall remain within the enclosure where it originates. If the source is located outside the building or structure supplied, a system bonding jumper shall be installed at the grounding electrode connection in compliance with 250.30(C).

Where a separately derived system has a grounded conductor, 250.30(A)(1) requires that a system bonding jumper be installed to connect the equipment grounding conductors to the grounded conductor. Equipment grounding conductors are connected to the grounding electrode system by the grounding electrode conductor. The system bonding jumper is sized according to 250.28(D) and may be located at any point between the source terminals (transformer, generator, etc.) and the first disconnecting means or overcurrent device. See the commentary following 250.28(D) for further information on sizing the system bonding jumper.

*Exception No. 1: For systems installed in accordance with 450.6, a single system bonding jumper connection to the tie point of the grounded circuit conductors from each power source shall be permitted.*

*Exception No. 2: A system bonding jumper at both the source and the first disconnecting means shall be permitted if doing so does not establish a parallel path for the grounded conductor. If a grounded conductor is used in this manner, it shall not be smaller than the size specified for the system bonding jumper but shall not be required to be larger than the ungrounded conductor(s). For the purposes of this exception, connection through the earth shall not be considered as providing a parallel path.*

*Exception No. 3: The size of the system bonding jumper for a system that supplies a Class 1, Class 2, or Class 3 circuit, and is derived from a transformer rated not more than 1000 volt-amperes, shall not be smaller than the derived ungrounded conductors and shall not be smaller than 14 AWG copper or 12 AWG aluminum.*

Section 250.30(A)(1) requires the system bonding jumper to be not smaller than the sizes given in Table 250.66; that is, not smaller than 8 AWG copper. Exception No. 3 to 250.30(A)(1) permits a system bonding jumper for a Class 1, Class 2, or Class 3 circuit to be not smaller than 14 AWG copper or 12 AWG aluminum.

(a) *Installed at the Source.* The system bonding jumper shall connect the grounded conductor to the supply-side bonding jumper and the normally non-current-carrying metal enclosure.

(b) *Installed at the First Disconnecting Means.* The system bonding jumper shall connect the grounded conductor to the supply-side bonding jumper, the disconnecting means enclosure, and the equipment grounding conductor(s).

The supply-side bonding jumper installed between the separately derived system enclosure and the enclosure of the first system disconnecting means provides the circuit ground-fault current, whether the system bonding jumper is installed at the source enclosure or at the disconnecting means enclosure. The supply-side bonding jumper can be a wire that is sized per 250.102(C) or it can be rigid metal conduit, intermediate metal conduit, or electrical metallic tubing installed between the two enclosures. Where the system operates at over 250 volts to ground, the raceway connections to enclosures must be made as specified in 250.97.

#### Application Example

The source of a separately derived system is a 75 kVA dry-type transformer. Liquidtight flexible metal conduit is used as the wiring method between the transformer and the 200-ampere fusible safety switch that is the first system disconnecting means. The system bonding jumper is installed in the safety switch enclosure. The ungrounded conductors are 3/0 AWG copper. The wiring method necessitates the installation of a wire-type supply-side bonding jumper. What is the minimum size for this bonding jumper?

#### Solution

The requirement covering the minimum size for the supply-side bonding jumper is 250.102(C). This section refers to Table 250.66 for sizing supply-side bonding jumpers where the ungrounded supply conductors are not greater than 1100-kcmil copper or 1750-kcmil aluminum. In this example, the largest ungrounded conductor size (3/0 AWG copper) is not greater than 1100-kcmil copper, which is the point at which 250.102(C) requires the bonding jumper size be calculated. Therefore, the supply-side bonding jumper size can be selected directly from Table 250.66.

From Table 250.66: 3/0 AWG ungrounded conductors = 4 AWG copper or 2 AWG aluminum supply-side bonding

jumper. The bonding jumper installed can be a bare, covered, or insulated conductor and can be installed inside the raceway or, where the length of the bonding jumper does not exceed 6 ft, it can be installed outside and routed with the raceway.

**(2) Supply-Side Bonding Jumper.** If the source of a separately derived system and the first disconnecting means are located in separate enclosures, a supply-side bonding jumper shall be installed with the circuit conductors from the source enclosure to the first disconnecting means. A supply-side bonding jumper shall not be required to be larger than the derived ungrounded conductors. The supply-side bonding jumper shall be permitted to be of nonflexible metal raceway type or of the wire or bus type as follows:

(a) A supply-side bonding jumper of the wire type shall comply with 250.102(C), based on the size of the derived ungrounded conductors.

(b) A supply-side bonding jumper of the bus type shall have a cross-sectional area not smaller than a supply-side bonding jumper of the wire type as determined in 250.102(C).

**(3) Grounded Conductor.** If a grounded conductor is installed and the system bonding jumper connection is not located at the source, 250.30(A)(3)(a) through (A)(3)(d) shall apply.

(a) *Sizing for a Single Raceway.* The grounded conductor shall not be smaller than the required grounding electrode conductor specified in Table 250.66 but shall not be required to be larger than the largest derived ungrounded conductor(s). In addition, for sets of derived ungrounded conductors larger than 1100 kcmil copper or 1750 kcmil aluminum, the grounded conductor shall not be smaller than 12½ percent of the circular mil area of the largest set of derived ungrounded conductors.

(b) *Parallel Conductors in Two or More Raceways.* If the ungrounded conductors are installed in parallel in two or more raceways, the grounded conductor shall also be installed in parallel. The size of the grounded conductor in each raceway shall be based on the total circular mil area of the parallel derived ungrounded conductors in the raceway as indicated in 250.30(A)(3)(a), but not smaller than 1/0 AWG.

Informational Note: See 310.10(H) for grounded conductors connected in parallel.

(c) *Delta-Connected System.* The grounded conductor of a 3-phase, 3-wire delta system shall have an ampacity not less than that of the ungrounded conductors.

(d) *Impedance Grounded System.* The grounded conductor of an impedance grounded neutral system shall be installed in accordance with 250.36 or 250.186, as applicable.

The provisions in 250.30(A)(3)(a) through (d) cover the minimum sizing requirements for the grounded conductor in a separately derived system relative to its function as the path for ground-fault current to return to the source. The provisions of (a) and (b) are similar to the requirements in 250.24(C)(1) and (C)(2) for the grounded service conductor. In addition, grounded and neutral conductors that carry current as part of normal circuit operation are required to be sized in accordance with 220.61.

**(4) Grounding Electrode.** The grounding electrode shall be as near as practicable to, and preferably in the same area as, the grounding electrode conductor connection to the system. The grounding electrode shall be the nearest of one of the following:

- (1) Metal water pipe grounding electrode as specified in 250.52(A)(1)
- (2) Structural metal grounding electrode as specified in 250.52(A)(2)

*Exception No. 1: Any of the other electrodes identified in 250.52(A) shall be used if the electrodes specified by 250.30(A)(4) are not available.*

*Exception No. 2 to (1) and (2): If a separately derived system originates in listed equipment suitable for use as service equipment, the grounding electrode used for the service or feeder equipment shall be permitted as the grounding electrode for the separately derived system.*

Informational Note No. 1: See 250.104(D) for bonding requirements for interior metal water piping in the area served by separately derived systems.

Informational Note No. 2: See 250.50 and 250.58 for requirements for bonding all electrodes together if located at the same building or structure.

If the location of the available electrode permits and in order to minimize the impedance of the connection to ground, 250.30(A)(4) requires the grounding electrode for a separately derived system to be in close proximity to the point at which the grounding electrode conductor connects to the system either at the source or at the first system disconnecting means. If a structural metal grounding electrode or a metal water pipe grounding electrode is available, 250.30(A)(4) requires the one closest to where the grounding electrode is connected to the system to be used. Where an effectively

grounded metal water pipe is used as the grounding electrode for a separately derived system, 250.68(C)(1) specifies that only the first 5 ft of water piping entering the building can be used as the point to make grounding electrode conductor connections or as a conductor to interconnect grounding electrodes.

The exception to 250.68(C)(1) permits metal water piping beyond the first 5 ft of where it enters the building to be used as a bonding conductor to interconnect other electrodes or as a grounding electrode conductor. This provision enables grounding electrode conductor connections to be made at other locations in the building or structure. However, the piping has to meet all of the conditions specified in this exception from the point where the piping enters the building to the point where the grounding electrode conductor connection is made. The other grounding electrodes covered in 250.52(A) can be used, but only where there is not a structural metal or metal water pipe–type grounding electrode available.

The practice of grounding the secondary of an isolating transformer to a ground rod or running the grounding electrode conductor back to the service ground (usually to reduce electrical noise on data processing systems) is not permitted where either of the electrodes covered in item (1) or item (2) of 250.30(A)(4) is available. However, an isolation transformer that is part of a listed power supply for a data processing room is not required to be grounded in accordance with 250.30(A)(4), but it must be grounded in accordance with the manufacturer's instructions.

**(5) Grounding Electrode Conductor, Single Separately Derived System.** A grounding electrode conductor for a single separately derived system shall be sized in accordance with 250.66 for the derived **ungrounded** conductors. It shall be used to connect the grounded conductor of the derived system to the grounding electrode as specified in 250.30(A)(4). This connection shall be made at the same point on the separately derived system where the system bonding jumper is connected.

**Exception No. 1:** If the system bonding jumper specified in 250.30(A)(1) is a wire or busbar, it shall be permitted to connect the grounding electrode conductor to the equipment grounding terminal, bar, or bus, provided the equipment grounding terminal, bar, or bus is of sufficient size for the separately derived system.

**Exception No. 2:** If a separately derived system originates in listed equipment suitable as service equipment, the grounding electrode conductor from the service or feeder equipment to the grounding electrode shall be permitted as the grounding electrode conductor for the separately derived system, provided the grounding electrode conductor is of sufficient size for the separately derived system. If the equipment grounding bus internal to the equipment is not

smaller than the required grounding electrode conductor for the separately derived system, the grounding electrode connection for the separately derived system shall be permitted to be made to the bus.

**Exception No. 3:** A grounding electrode conductor shall not be required for a system that supplies a Class 1, Class 2, or Class 3 circuit and is derived from a transformer rated not more than 1000 volt-amperes, provided the grounded conductor is bonded to the transformer frame or enclosure by a jumper sized in accordance with 250.30(A)(1), Exception No. 3, and the transformer frame or enclosure is grounded by one of the means specified in 250.134.

If a separately derived system is required to be grounded, the conductor to be grounded is allowed to be connected to the grounding electrode system at any location between the source terminals (transformer, generator, etc.) and the first disconnecting means or overcurrent device. The location of the grounding electrode conductor connection to the grounded conductor must be at the point at which the system bonding jumper is connected to the grounded conductor. By establishing a common point of connection, normal neutral current will be carried only on the system grounded conductor and it will not be imposed on parallel paths such as metal raceways, piping systems, and structural steel. Exhibits 250.13 and 250.14 illustrate two acceptable locations for

**EXHIBIT 250.13** A grounding arrangement for a separately derived system in which the grounding electrode conductor connection is made at the source of the separately derived system (transformer).

**EXHIBIT 250.14** A grounding arrangement for a separately derived system in which the grounding electrode conductor connection is made at the first system disconnecting means.

connecting the grounding electrode conductor to the grounded conductor of a separately derived system. These exhibits depict typical wiring arrangements for dry-type transformers supplied from a 480-volt, 3-phase feeder to derive a 208Y/120-volt or 480Y/277-volt secondary. In Exhibit 250.13, this grounding electrode conductor connection is made at the source of the separately derived system (in the transformer enclosure where the system bonding jumper is also installed). In Exhibit 250.14, the grounding electrode conductor connection is made at the first disconnecting means where the system bonding jumper is installed. With the grounding electrode conductor, the bonding jumper, and the bonding of the grounded circuit conductor (neutral) connected as shown, line-to-ground fault currents are able to return to the supply source through a short, low-impedance path. A path of lower impedance is provided that facilitates the operation of overcurrent devices, in accordance with 250.4(A)(5). The grounding electrode conductor connected to the secondary grounded circuit conductor is sized according to Table 250.66.

**(6) Grounding Electrode Conductor, Multiple Separately Derived Systems.** A common grounding electrode conductor for multiple separately derived systems shall be permitted. If installed, the common grounding electrode conductor shall be used to connect the grounded conductor of the separately derived systems to the grounding electrode as specified in 250.30(A)(4). A grounding electrode conductor tap shall then be installed from each separately derived

system to the common grounding electrode conductor. Each tap conductor shall connect the grounded conductor of the separately derived system to the common grounding electrode conductor. This connection shall be made at the same point on the separately derived system where the system bonding jumper is connected.

**Exception No. 1:** If the system bonding jumper specified in 250.30(A)(1) is a wire or busbar, it shall be permitted to connect the grounding electrode conductor tap to the equipment grounding terminal, bar, or bus, provided the equipment grounding terminal, bar, or bus is of sufficient size for the separately derived system.

**Exception No. 2:** A grounding electrode conductor shall not be required for a system that supplies a Class 1, Class 2, or Class 3 circuit and is derived from a transformer rated not more than 1000 volt-amperes, provided the system grounded conductor is bonded to the transformer frame or enclosure by a jumper sized in accordance with 250.30(A)(1), Exception No. 3, and the transformer frame or enclosure is grounded by one of the means specified in 250.134.

(a) **Common Grounding Electrode Conductor.** The common grounding electrode conductor shall be permitted to be one of the following:

- (1) A conductor of the wire type not smaller than 3/0 AWG copper or 250 kcmil aluminum
- (2) The metal frame of the building or structure that complies with 250.52(A)(2) or is connected to the grounding electrode system by a conductor that shall not be smaller than 3/0 AWG copper or 250 kcmil aluminum

(b) **Tap Conductor Size.** Each tap conductor shall be sized in accordance with 250.66 based on the derived ungrounded conductors of the separately derived system it serves.

**Exception:** If a separately derived system originates in listed equipment suitable as service equipment, the grounding electrode conductor from the service or feeder equipment to the grounding electrode shall be permitted as the grounding electrode conductor for the separately derived system, provided the grounding electrode conductor is of sufficient size for the separately derived system. If the equipment ground bus internal to the equipment is not smaller than the required grounding electrode conductor for the separately derived system, the grounding electrode connection for the separately derived system shall be permitted to be made to the bus.

(c) **Connections.** All tap connections to the common grounding electrode conductor shall be made at an accessible location by one of the following methods:

- (1) A connector listed as grounding and bonding equipment.
- (2) Listed connections to aluminum or copper busbars not smaller than 6 mm × 50 mm (¼ in. × 2 in.). If aluminum busbars are used, the installation shall comply with 250.64(A).
- (3) The exothermic welding process.

Tap conductors shall be connected to the common grounding electrode conductor in such a manner that the common grounding electrode conductor remains without a splice or joint.

A common grounding electrode conductor serving several separately derived systems is permitted by 250.30(A)(6) as an alternative to installing individual grounding electrode conductors from each separately derived system to the grounding electrode system. A tapped grounding electrode conductor is installed from the common grounding electrode conductor to the point of connection to the individual separately derived system grounded conductor. This tap is sized from Table 250.66 based on the size of the ungrounded conductors for that individual separately derived system.

So that the grounding electrode conductor always has sufficient size to accommodate the multiple separately derived systems that it serves, the minimum size for this conductor is 3/0 AWG copper or 250-kcmil aluminum. This minimum size for the common grounding electrode conductor correlates with the maximum size grounding electrode conductor required by Table 250.66; therefore, the 3/0 AWG copper or 250-kcmil aluminum becomes the maximum size required for the common grounding electrode conductor. The sizing requirement for the common grounding electrode conductor is specified in 250.30(A)(6)(a), and the sizing requirement for the individual taps to the common grounding electrode conductor is specified in 250.30(A)(6)(b).

The methods of connecting the individual tap conductor(s) to the common grounding electrode conductor are specified in 250.30(A)(6)(c). The permitted methods include the use of busbar as a point of connection between the taps and the common GEC. The connections to the busbar must be made using a listed means. Exhibit 250.15 shows a copper busbar used as a connection point for the individual taps from multiple separately derived systems to be connected to the common grounding electrode.

The following example, together with Exhibit 250.16, illustrate the use of a common grounding electrode conductor for grounding multiple separately derived systems (transformers in this case).

#### Calculation Example

A building is being renovated for use as an office building. The building is being furnished with four 45-kVA, 480 to 120/208-volt, 3-phase, 4-wire, wye-connected transformers.

**EXHIBIT 250.15** Listed connectors used to connect the common grounding electrode conductor and individual taps to a centrally located copper busbar with a minimum dimension of ¼ in. thick by 2 in. wide.

Each transformer secondary supplies an adjacent 150-ampere main circuit breaker panelboard using 1/0 AWG, Type THHN copper conductors. The transformers are strategically placed throughout the building to facilitate efficient distribution. Because there is no accessible effectively grounded structural steel in the same areas as where the transformers are installed and the metal water piping is concealed after it leaves the lower level, each transformer secondary (separately derived system) must be grounded to the water service electrode within the first 5 ft of entry into the building. A common grounding electrode conductor has been selected as the method to connect all the transformers to the grounding electrode system.

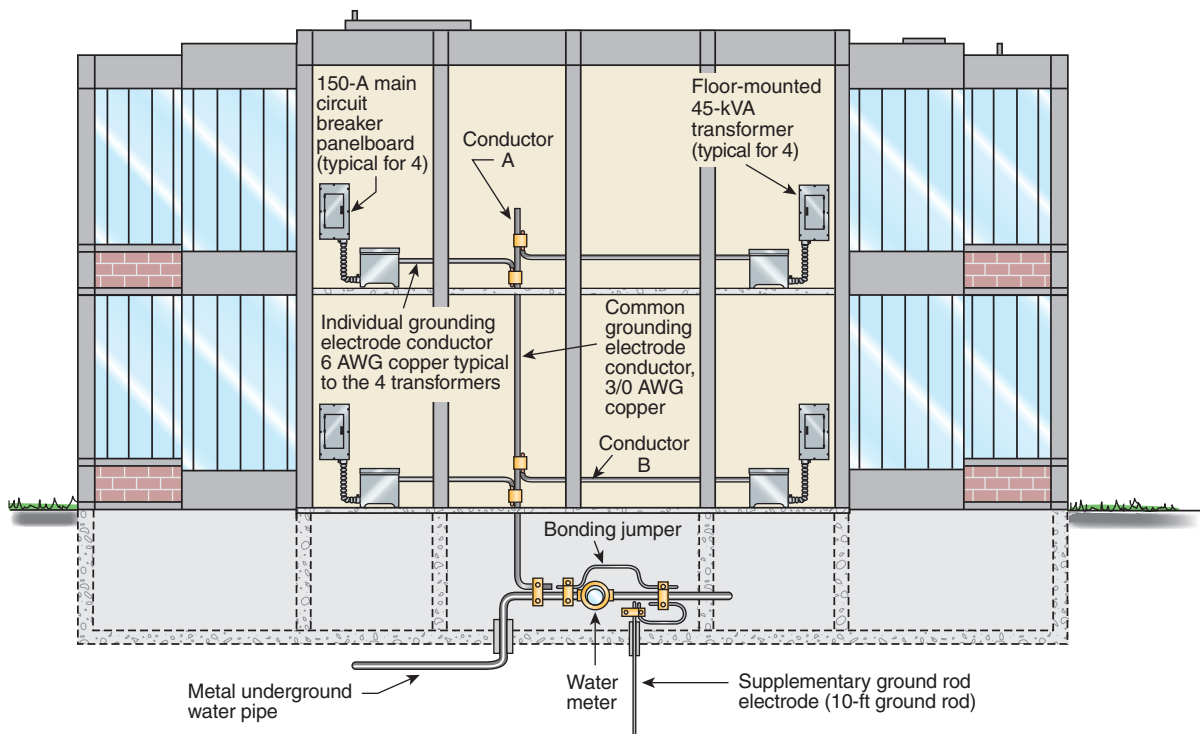

What is the minimum-size common grounding electrode conductor that must be used to connect the four transformers to the grounding electrode system? What is the minimum-size grounding electrode conductor to connect each of the four transformers to the common grounding electrode conductor?

#### Solution

STEP 1. Determine the minimum size for the common grounding electrode conductor.

Minimum size required [per 250.30(A)(6)(a)]:  
 3/0 copper  
 or 250-kcmil aluminum

The common grounding electrode conductor does not have to be sized larger than specified by this requirement. Additional transformers installed in the building can be connected to this common grounding electrode conductor, and no increase in its size is required.

**EXHIBIT 250.16** The grounding arrangement for multiple separately derived systems using taps from a common grounding electrode conductor, according to 250.30(A)(6)(a) and (A)(6)(b).

**STEP 2.** Determine the size of each individual grounding electrode tap conductor for each of the separately derived systems. According to Table 250.66, a 1/0 AWG copper derived phase conductor requires a conductor not smaller than 6 AWG copper for each transformer grounding electrode tap conductor. This individual grounding electrode conductor will be used as the permitted tap conductor and will run from where it connects to the grounded conductor in the transformer to a connection point located on the common grounding electrode conductor. This conductor is labeled “Conductor B” in Exhibit 250.16.

**(7) Installation.** The installation of all grounding electrode conductors shall comply with 250.64(A), (B), (C), and (E).

**(8) Bonding.** Structural steel and metal piping shall be connected to the grounded conductor of a separately derived system in accordance with 250.104(D).

**(B) Ungrounded Systems.** The equipment of an ungrounded separately derived system shall be grounded and bonded as specified in 250.30(B)(1) through (B)(3).

**(1) Grounding Electrode Conductor.** A grounding electrode conductor, sized in accordance with 250.66 for the

largest derived ungrounded conductor (s) or set of derived ungrounded conductors, shall be used to connect the metal enclosures of the derived system to the grounding electrode as specified in 250.30(A)(5) or (6), as applicable. This connection shall be made at any point on the separately derived system from the source to the first system disconnecting means. If the source is located outside the building or structure supplied, a grounding electrode connection shall be made in compliance with 250.30(C).

For ungrounded separately derived systems, a grounding electrode conductor is required by 250.30(B)(1) to be connected to the metal enclosure of the system disconnecting means. The grounding electrode conductor is sized from Table 250.66 based on the largest ungrounded supply conductor. This connection establishes a reference to ground for all exposed non-current-carrying metal equipment supplied from the ungrounded system. The equipment grounding conductors of circuits supplied from the ungrounded system are connected to ground via this grounding electrode conductor connection.

**(2) Grounding Electrode.** Except as permitted by 250.34 for portable and vehicle-mounted generators, the grounding electrode shall comply with 250.30(A)(4).

**(3) Bonding Path and Conductor.** A supply-side bonding jumper shall be installed from the source of a separately derived system to the first disconnecting means in compliance with 250.30(A)(2).

**(C) Outdoor Source.** If the source of the separately derived system is located outside the building or structure supplied, a grounding electrode connection shall be made at the source location to one or more grounding electrodes in compliance with 250.50. In addition, the installation shall comply with 250.30(A) for grounded systems or with 250.30(B) for ungrounded systems.

*Exception: The grounding electrode conductor connection for impedance grounded neutral systems shall comply with 250.36 or 250.186, as applicable.*

This provision is similar in function to the requirement of 250.24(A)(2) in that it affords the benefit of an outdoor grounding connection at the source of a separately derived system. This connection provides a “first line of defense” for the system against the effects of overvoltages due to lightning, transients, or accidental contact between conductors of systems operating at different voltages.

## 250.32 Buildings or Structures Supplied by a Feeder(s) or Branch Circuit(s)

**(A) Grounding Electrode.** Building(s) or structure(s) supplied by feeder(s) or branch circuit(s) shall have a grounding electrode or grounding electrode system installed in accordance with Part III of Article 250. The grounding electrode conductor(s) shall be connected in accordance with 250.32(B) or (C). Where there is no existing grounding electrode, the grounding electrode(s) required in 250.50 shall be installed.

Where a building or structure is supplied by a feeder or branch circuit, 250.32(A) requires that a grounding electrode system be established at each building or structure supplied, unless one already exists. The equipment grounding bus must be bonded to the grounding electrode system as is shown for Buildings 2 and 3 in Exhibit 250.17. Building 1 is supplied by a service and is grounded in accordance with 250.24(A) through (D), and the disconnecting means enclosure, building steel, and interior metal water piping are also required to be bonded to the grounding electrode system. All exposed non-current-carrying metal parts of electrical equipment are required to be grounded through equipment grounding conductor connections to the equipment grounding bus at the building disconnecting means. The grounded conductor of the feeder supplying Building 2 is permitted to

**EXHIBIT 250.17** Example of grounding electrode systems required at feeder-supplied Building 2 and Building 3, in accordance with 250.32(A) and (B).

be “re-grounded” per 250.32(B)(1), Exception. An equipment grounding conductor is run with the feeder to Building 3 as specified in the general requirement of 250.32(B).

*Exception: A grounding electrode shall not be required where only a single branch circuit, including a multiwire branch circuit, supplies the building or structure and the branch circuit includes an equipment grounding conductor for grounding the normally non-current-carrying metal parts of equipment.*

The exception to 250.32(A) exempts a building or structure supplied by a single branch circuit (2-wire or multiwire) from the grounding electrode requirement provided an equipment grounding conductor is installed with or encloses the branch circuit. Detached garages, sheds, and similar structures supplied by a single branch circuit are examples of where this exception can be applied. See Exhibit 250.18 for an example of this provision.

## (B) Grounded Systems.

**(1) Supplied by a Feeder or Branch Circuit.** An equipment grounding conductor, as described in 250.118, shall be run with the supply conductors and be connected to the building or structure disconnecting means and to the grounding electrode(s). The equipment grounding conductor shall be used for grounding or bonding of equipment, structures, or frames required to be grounded or bonded. The equipment grounding conductor shall be sized in accordance with 250.122. Any installed grounded conductor shall not be connected to the equipment grounding conductor or to the grounding electrode(s).

**EXHIBIT 250.18** An installation where a connection from the single branch-circuit disconnecting means enclosure to a grounding electrode system is not required at the remote building because an equipment grounding conductor is installed with the circuit conductors.

*Exception:* For installations made in compliance with previous editions of this Code that permitted such connection, the grounded conductor run with the supply to the building or structure shall be permitted to serve as the ground-fault return path if all of the following requirements continue to be met:

Section 250.32(B) requires the installation of an equipment grounding conductor with all feeders and branch circuits that supply a building or structure. Using the grounded conductor to ground equipment, in lieu of installing a separate equipment grounding conductor, creates parallel paths for normal neutral current along metal raceways, metal piping, metal cable sheaths or shields, and other metal structures such as ductwork. Installing an equipment grounding conductor with the supply circuit conductors helps ensure that normal circuit current is not imposed on continuous metal paths other than the insulated grounded or neutral conductor. At a building or structure supplied by a feeder or branch circuit, the equipment grounding conductor is connected to the grounding electrode system [unless the installation complies with 250.32(A), Exception] in the equipment supplied by the feeder or branch circuit. Where installed, the grounded or neutral conductor is electrically isolated from the equipment grounding conductor and any grounding electrodes at the building or structure supplied by the feeder or branch circuit as illustrated in Exhibit 250.19.

**EXHIBIT 250.19** An installation performed in accordance with 250.32(B)(1) in which a connection between the grounded conductor (neutral) and equipment grounding terminal bar is not permitted. A connection from the equipment grounding terminal bus to the grounding electrode is required.

Because “re-grounding” the neutral or grounded conductor was permitted in previous editions of the Code, the Exception to 250.32(B) permits limited applications of using the grounded conductor for grounding and bonding of equipment and systems but only for circuits that were installed in compliance with the Code prior to the 2008 edition and where the three conditions specified in the current exception are met.

- (1) An equipment grounding conductor is not run with the supply to the building or structure.
- (2) There are no continuous metallic paths bonded to the grounding system in each building or structure involved.
- (3) Ground-fault protection of equipment has not been installed on the supply side of the feeder(s).

*If the grounded conductor is used for grounding in accordance with the provision of this exception, the size of the grounded conductor shall not be smaller than the larger of either of the following:*

- (1) That required by 220.61
- (2) That required by 250.122

## (2) Supplied by Separately Derived System.

(a) *With Overcurrent Protection.* If overcurrent protection is provided where the conductors originate, the installation shall comply with 250.32(B)(1).

(b) *Without Overcurrent Protection.* If overcurrent protection is not provided where the conductors originate, the installation shall comply with 250.30(A). If installed, the supply-side bonding jumper shall be connected to the building or structure disconnecting means and to the grounding electrode(s).

Section 250.32(B)(2)(a) and (b) correlate the grounding and bonding requirements for separately derived systems with the requirements for grounding and bonding at buildings or structures supplied by a feeder or branch circuit that originates in outdoor equipment such as a transformer or generator. The grounding and bonding provisions are predicated on the location of the overcurrent protective device. For example, if a separately derived system originates in a generator and an overcurrent protective device is installed at the generator to protect the feeder, an equipment grounding conductor is required to be installed with the feeder conductors. The separately derived system is grounded as specified in 250.30(C) for outdoor sources. Where there is a disconnecting means at the building [provisions in 700.12(B)(6), 701.12(B)(5), and 702.12 amend the general disconnecting means requirement in 225.31 and 225.32], the equipment grounding conductor is connected to the disconnecting means enclosure and to the building's grounding electrode system. This installation is no different from what is required for feeders originating in another building. Where an overcurrent protective device is not located at the source (as is the case with many outdoor transformer installations), the grounding and bonding provisions of 250.30(A) apply and a supply-side bonding jumper is used to complete the ground-fault current path between the building or structure supplied and the source.

### (C) Ungrounded Systems.

(1) **Supplied by a Feeder or Branch Circuit.** An equipment grounding conductor, as described in 250.118, shall be installed with the supply conductors and be connected to the building or structure disconnecting means and to the grounding electrode(s). The grounding electrode(s) shall also be connected to the building or structure disconnecting means.

### (2) Supplied by a Separately Derived System.

(a) *With Overcurrent Protection.* If overcurrent protection is provided where the conductors originate, the installation shall comply with (C)(1).

(b) *Without Overcurrent Protection.* If overcurrent protection is not provided where the conductors originate, the installation shall comply with 250.30(B). If installed, the supply-side bonding jumper shall be connected to the build-

ing or structure disconnecting means and to the grounding electrode(s).

### (D) Disconnecting Means Located in Separate Building or Structure on the Same Premises.

Where one or more disconnecting means supply one or more additional buildings or structures under single management, and where these disconnecting means are located remote from those buildings or structures in accordance with the provisions of 225.32, Exception No. 1 and No. 2, 700.12(B)(6), 701.12(B)(5), or 702.12, all of the following conditions shall be met:

- (1) The connection of the grounded conductor to the grounding electrode, to normally non-current-carrying metal parts of equipment, or to the equipment grounding conductor at a separate building or structure shall not be made.
- (2) An equipment grounding conductor for grounding and bonding any normally non-current-carrying metal parts of equipment, interior metal piping systems, and building or structural metal frames is run with the circuit conductors to a separate building or structure and connected to existing grounding electrode(s) required in Part III of this article, or, where there are no existing electrodes, the grounding electrode(s) required in Part III of this article shall be installed where a separate building or structure is supplied by more than one branch circuit.
- (3) The connection between the equipment grounding conductor and the grounding electrode at a separate building or structure shall be made in a junction box, panelboard, or similar enclosure located immediately inside or outside the separate building or structure.

Section 250.32(D) applies where the disconnecting means is not located in the building or structure supplied by a feeder or branch circuit. Exceptions to 225.32 and provisions within 700.12(B)(6), 701.12(B)(5) and 702.12 permit the disconnecting means to be located elsewhere from the building or structure being supplied. The requirement to make a connection to a grounding electrode system at these buildings or structures still applies, but there is no disconnecting means available in which the connection can be made. The provisions in 250.32(D)(1) through (3) allow for the required connection to be made in a panelboard, junction box, or similar enclosure that is located either inside or outside of the building or structure being supplied at a point nearest to where the supply conductors enter the building or structure. An equipment grounding conductor must be run with the supply conductors, the grounded conductor (where installed) must not be bonded to the enclosure or equipment grounding bus, and the equipment grounding bus must be connected to

a new or existing grounding electrode system at the second building. All non-current-carrying metal parts of equipment, building steel, and interior metal piping systems must be connected to the grounding electrode system. Exhibit 250.20 illustrates an installation in which Building 1 houses the disconnecting means for Building 2.

**EXHIBIT 250.20** Grounding and bonding requirements for a separate building under single management with the disconnect remotely located from the building.

**(E) Grounding Electrode Conductor.** The size of the grounding electrode conductor to the grounding electrode(s) shall not be smaller than given in 250.66, based on the largest ungrounded supply conductor. The installation shall comply with Part III of this article.

The grounding electrode conductor installed at buildings or structures supplied by feeders or branch circuits provides the same function as the grounding electrode conductor installed for a service-supplied building or structure. Therefore, all of the installation requirements contained in Part III of Article 250, including the sizing requirement of 250.66, are applicable.

### 250.34 Portable and Vehicle-Mounted Generators

**(A) Portable Generators.** The frame of a portable generator shall not be required to be connected to a grounding electrode as defined in 250.52 for a system supplied by the generator under the following conditions:

- (1) The generator supplies only equipment mounted on the generator, cord-and-plug-connected equipment through receptacles mounted on the generator, or both, and
- (2) The normally non-current-carrying metal parts of equipment and the equipment grounding conductor terminals of the receptacles are connected to the generator frame.

minerals of the receptacles are connected to the generator frame.

According to 250.34(A), the frame of a portable generator is not required to be connected to earth (ground rod, water pipe, etc.) if the generator has receptacles mounted on the generator panel and the receptacles have equipment grounding terminals bonded to the generator frame. *Portable* describes equipment that is easily carried by personnel from one location to another. *Mobile* describes equipment, such as vehicle-mounted generators, that is capable of being moved on wheels or rollers.

**(B) Vehicle-Mounted Generators.** The frame of a vehicle shall not be required to be connected to a grounding electrode as defined in 250.52 for a system supplied by a generator located on this vehicle under the following conditions:

- (1) The frame of the generator is bonded to the vehicle frame, and
- (2) The generator supplies only equipment located on the vehicle or cord-and-plug-connected equipment through receptacles mounted on the vehicle, or both equipment located on the vehicle and cord-and-plug-connected equipment through receptacles mounted on the vehicle or on the generator, and
- (3) The normally non-current-carrying metal parts of equipment and the equipment grounding conductor terminals of the receptacles are connected to the generator frame.

Vehicle-mounted generators that provide a neutral conductor and are installed as separately derived systems supplying equipment and receptacles on the vehicle are required to have the neutral conductor bonded to the generator frame and to the vehicle frame. The non-current-carrying parts of the equipment must be bonded to the generator frame.

**(C) Grounded Conductor Bonding.** A system conductor that is required to be grounded by 250.26 shall be connected to the generator frame where the generator is a component of a separately derived system.

**Informational Note:** For grounding portable generators supplying fixed wiring systems, see 250.30.

Portable and vehicle-mounted generators that are installed as separately derived systems and that provide a neutral conductor (such as 3-phase, 4-wire wye-connected; single-phase 240/120 volt; or 3-phase, 4-wire delta connected) are required to have the neutral conductor bonded to the generator frame.

### 250.35 Permanently Installed Generators

A conductor that provides an effective ground-fault current path shall be installed with the supply conductors from a permanently installed generator(s) to the first disconnecting mean(s) in accordance with (A) or (B).

**(A) Separately Derived System.** If the generator is installed as a separately derived system, the requirements in 250.30 shall apply.

**(B) Nonseparately Derived System.** If the generator is installed as a nonseparately derived system, and overcurrent protection is not integral with the generator assembly, a supply-side bonding jumper shall be installed between the generator equipment grounding terminal and the equipment grounding terminal, bar, or bus of the disconnecting mean(s). It shall be sized in accordance with 250.102(C) based on the size of the conductors supplied by the generator.

The requirements of 250.35(B) create a return path for ground-fault current for permanently installed generators supplying a system that is not separately derived and the first system overcurrent protective device is not installed at the generator. The conductor used to conduct ground-fault current between the first system disconnecting means and the generator is a supply-side bonding jumper, which is permitted to be a nonflexible metal raceway or a wire. Wire-type supply-side bonding jumpers are sized using 250.102(C). For many installations, the size can be selected directly from Table 250.66.

#### Calculation Example

A 100-kW generator operating at 480Y/277 volts, 3-phase, 4-wire is connected to the premises wiring via 200-ampere-rated transfer equipment. The transfer equipment has a solid neutral connection, and thus is not a separately derived system. Determine the size of the wire-type supply-side bonding conductor required for this installation. There is no overcurrent protective device installed at the generator. The conductors terminate in a 125-ampere overcurrent protective device installed in the transfer equipment. The ungrounded conductors between the output terminals of the generator and the transfer equipment have been sized in accordance with 445.13 and are 1/0 AWG copper with THWN insulation.

#### Solution

Section 250.35(B) refers to 250.102(C) for sizing supply-side equipment bonding jumpers. The minimum size is based on the size of the ungrounded conductors between the generator and the transfer equipment using Table 250.66.

From Table 250.66:

1/0 AWG ungrounded conductors → 6 AWG copper  
or 4 AWG aluminum

Either of these conductors, installed with the circuit conductors from the generator output terminals to the equipment grounding terminal of the transfer equipment, meets the requirements of 250.35(B).

### 250.36 High-Impedance Grounded Neutral Systems

High-impedance grounded neutral systems in which a grounding impedance, usually a resistor, limits the ground-fault current to a low value shall be permitted for 3-phase ac systems of 480 volts to 1000 volts if all the following conditions are met:

- (1) The conditions of maintenance and supervision ensure that only qualified persons service the installation.
- (2) Ground detectors are installed on the system.
- (3) Line-to-neutral loads are not served.

High-impedance grounded neutral systems shall comply with the provisions of 250.36(A) through (G).

Section 250.36 contains the requirements for installing high-impedance grounded neutral systems that operate from 480 to 1000 volts. Systems rated over 1000 volts are covered in 250.186. For information on the differences between solidly grounded systems and high-impedance grounded neutral systems, see “Grounding for Emergency and Standby Power Systems,” by Robert B. West, *IEEE Transactions on Industry Applications*, Vol. IA-15, No. 2, March/April 1979.

As the diagram in Exhibit 250.21 shows, the location of the grounding impedance device (resistor used in this example) in a high-impedance grounded neutral system limits the amount of ground-fault current in the neutral conductor

**EXHIBIT 250.21** Diagram of a high-impedance grounded neutral system.

when a line-to-ground fault occurs. The grounding impedance is usually selected to limit fault current to a value that is slightly greater than or equal to the capacitive charging current. This system is used where continuity of power is required. Therefore, a ground fault results in an alarm condition rather than in the tripping of a circuit breaker, which allows a safe and orderly shutdown of a process in which a non-orderly shutdown can introduce additional or increased hazards.

**(A) Grounding Impedance Location.** The grounding impedance shall be installed between the grounding electrode conductor and the system neutral point. If a neutral point is not available, the grounding impedance shall be installed between the grounding electrode conductor and the neutral point derived from a grounding transformer.

**(B) Grounded System Conductor.** The grounded system conductor from the neutral point of the transformer or generator to its connection point to the grounding impedance shall be fully insulated.

The grounded system conductor shall have an ampacity of not less than the maximum current rating of the grounding impedance but in no case shall the grounded system conductor be smaller than 8 AWG copper or 6 AWG aluminum or copper-clad aluminum.

The size of the neutral conductor is determined by the amount of ground-fault current that can be conducted through the grounding impedance. The minimum 8 AWG copper or 4 AWG aluminum conductor sizes reflect the minimum sizes specified in Table 250.66, which is referred to by 250.24(C)(1) and 250.30(A)(3)(a) for sizing grounded (neutral) conductors.

**(C) System Grounding Connection.** The system shall not be connected to ground except through the grounding impedance.

**Informational Note:** The impedance is normally selected to limit the ground-fault current to a value slightly greater than or equal to the capacitive charging current of the system. This value of impedance will also limit transient overvoltages to safe values. For guidance, refer to criteria for limiting transient overvoltages in ANSI/IEEE 142-1991, *Recommended Practice for Grounding of Industrial and Commercial Power Systems*.

For additional information on the system grounding connection in 250.36(C), see “Charging Current Data for Guesswork-Free Design of High-Resistance Grounded Systems,” by D. S. Baker, *IEEE Transactions on Industry Applications*,

Vol. IA-15, No. 2, March/April 1979; and “High-Resistance Grounding,” by Baldwin Bridger, Jr., *IEEE Transactions on Industry Applications*, Vol. IA-19, No. 1, January/February 1983.

**(D) Neutral Point to Grounding Impedance Conductor Routing.** The conductor connecting the neutral point of the transformer or generator to the grounding impedance shall be permitted to be installed in a separate raceway from the ungrounded conductors. It shall not be required to run this conductor with the phase conductors to the first system disconnecting means or overcurrent device.

**(E) Equipment Bonding Jumper.** The equipment bonding jumper (the connection between the equipment grounding conductors and the grounding impedance) shall be an unspliced conductor run from the first system disconnecting means or overcurrent device to the grounded side of the grounding impedance.

**(F) Grounding Electrode Conductor Location.** The grounding electrode conductor shall be connected at any point from the grounded side of the grounding impedance to the equipment grounding connection at the service equipment or first system disconnecting means.

**(G) Equipment Bonding Jumper Size.** The equipment bonding jumper shall be sized in accordance with (1) or (2) as follows:

- (1) If the grounding electrode conductor connection is made at the grounding impedance, the equipment bonding jumper shall be sized in accordance with 250.66, based on the size of the service entrance conductors for a service or the derived phase conductors for a separately derived system.
- (2) If the grounding electrode conductor is connected at the first system disconnecting means or overcurrent device, the equipment bonding jumper shall be sized the same as the neutral conductor in 250.36(B).

### III. Grounding Electrode System and Grounding Electrode Conductor

#### 250.50 Grounding Electrode System

All grounding electrodes as described in 250.52(A)(1) through (A)(7) that are present at each building or structure served shall be bonded together to form the grounding electrode system. Where none of these grounding electrodes exist, one or more of the grounding electrodes specified in 250.52(A)(4) through (A)(8) shall be installed and used.

Section 250.50 introduces the important concept of a *grounding electrode system*, in which all electrodes that are present at a building or structure are bonded together, as illustrated in Exhibit 250.22. Rather than total reliance on a single grounding electrode to perform its function over the life of the electrical installation, the *NEC* requires the formation of a system of electrodes where there are multiple grounding electrodes at the building being served. Metal structural members, metal water pipe, and concrete footings or foundations are found in many buildings and structures and are required to be integrated into the grounding electrode system if they qualify under the conditions specified in 250.52(A). The *Code* does not specify that metal water pipe, structural metal frame, or concrete-encased type electrodes have to be installed, only that they are to be used as components of the grounding electrode system where they have been installed as part of the building construction. A system of electrodes adds a level of reliability and helps ensure system performance over a long period of time.

**EXHIBIT 250.22** A grounding electrode system that uses the metal frame of a building, a ground ring, a concrete-encased electrode, a metal underground water pipe, and a ground rod.

*Exception: Concrete-encased electrodes of existing buildings or structures shall not be required to be part of the grounding electrode system where the steel reinforcing bars or rods are not accessible for use without disturbing the concrete.*

The exception exempts existing buildings and structures where access to the concrete-encased electrode would in-

volve some type of demolition or similar activity that would disturb the existing construction. Because the installation of the footings and foundation is one of the first elements of a construction project, and in most cases has long been completed by the time the electric service is installed, this rule necessitates an awareness and coordinated effort on the part of designers and the construction trades in making sure that the concrete-encased electrode is incorporated into the grounding electrode system.

## 250.52 Grounding Electrodes

### (A) Electrodes Permitted for Grounding.

**(1) Metal Underground Water Pipe.** A metal underground water pipe in direct contact with the earth for 3.0 m (10 ft) or more (including any metal well casing bonded to the pipe) and electrically continuous (or made electrically continuous by bonding around insulating joints or insulating pipe) to the points of connection of the grounding electrode conductor and the bonding conductor(s) or jumper(s), if installed.

The effectiveness of underground water piping as a grounding electrode for electrical systems has long been recognized, but in the early years of the *NEC* concerns over the effect of electric current on metal water piping created some uncertainty as to whether metal water piping systems should be used as grounding electrodes. To address those concerns, the electrical industry and the waterworks industry formed a committee to evaluate the use of metal underground water piping systems as grounding electrodes. Based on its findings, the committee issued an authoritative report on the subject. The International Association of Electrical Inspectors published the report, *Interim Report of the American Research Committee on Grounding*, in January 1944 (reprinted March 1949).

The National Institute of Standards and Technology (NIST) has monitored the electrolysis of metal systems because current at a grounding electrode on dc systems can cause displacement of metal. The results of this monitoring have shown that problems are minimal.

**(2) Metal Frame of the Building or Structure.** The metal frame of the building or structure that is connected to the earth by **one or more** of the following methods:

- (1) At least one structural metal member that is in direct contact with the earth for 3.0 m (10 ft) or more, with or without concrete encasement.
- (2) Hold-down bolts securing the structural steel column that are connected to a concrete-encased electrode that

complies with 250.52(A)(3) and is located in the support footing or foundation. The hold-down bolts shall be connected to the concrete-encased electrode by welding, exothermic welding, the usual steel tie wires, or other approved means.

Section 250.52(A)(2) provides two conditions under which the metal frame of a building or structure can be judged suitable for use as an individual grounding electrode. Under the first condition specified in 250.52(A)(2) the metal frame of the building can be considered an electrode if there is structural steel in direct contact with the earth for at least 10 ft or if the structural steel is encased in concrete in contact with the earth for at least 10 ft. The second condition requires the bolts used to secure the structural steel column (hold-down bolts) to be connected to a concrete-encased electrode installed per 250.52(A)(3). This connection is not required to occur at more than one building column or structural member and as long as there is electrical continuity through the entire metal frame of the building, the single connection to earth allows the entire structural metal building frame to be used as a grounding electrode. Building steel connected to earth using means other than those specified in 250.52(A)(2) is not permitted to be used as a grounding electrode, but can be used as a bonding conductor or grounding electrode conductor in accordance with the provisions of 250.68(C)(2).

**(3) Concrete-Encased Electrode.** A concrete-encased electrode shall consist of at least 6.0 m (20 ft) of either (1) or (2):

- (1) One or more bare or zinc galvanized or other electrically conductive coated steel reinforcing bars or rods of not less than 13 mm (½ in.) in diameter, installed in one continuous 6.0 m (20 ft) length, or if in multiple pieces connected together by the usual steel tie wires, exothermic welding, welding, or other effective means to create a 6.0 m (20 ft) or greater length; or
- (2) Bare copper conductor not smaller than 4 AWG

Metallic components shall be encased by at least 50 mm (2 in.) of concrete and shall be located horizontally within that portion of a concrete foundation or footing that is in direct contact with the earth or within vertical foundations or structural components or members that are in direct contact with the earth. If multiple concrete-encased electrodes are present at a building or structure, it shall be permissible to bond only one into the grounding electrode system.

**Informational Note:** Concrete installed with insulation, vapor barriers, films or similar items separating the concrete from the earth is not considered to be in “direct contact” with the earth.

To qualify as a grounding electrode, the horizontal or vertical installation of the steel reinforcing rod or the 4 AWG bare copper conductor within the concrete encasement is to be in one continuous 20 ft length so that there is a 20 ft long electrode in contact with the earth. Shorter lengths of reinforcing rod can be connected together to form an electrode 20 ft or longer using the connection methods identified in this requirement. Section 250.52(A)(3) only requires that a single concrete-encased electrode be incorporated into the grounding electrode system. Some buildings or structures may have discontinuous segments of a footing or foundation that individually qualify as grounding electrodes per this section, and once one has been bonded to the grounding electrode system, the remaining ones are exempt from any bonding or grounding requirements. Exhibit 250.23 shows an example of a concrete-encased electrode embedded horizontally. As indicated in the informational note, direct contact with the earth means that there is no medium between the concrete and the earth that impedes the grounding connection or insulates the concrete from being in direct contact with the earth.

**EXHIBIT 250.23** An example of a concrete-encased electrode that is required to be incorporated into the grounding electrode system. The horizontally installed reinforcing rod located near the bottom of the footing must consist of either a single 20-ft continuous section or multiple sections connected together in a 20-ft continuous length.

**(4) Ground Ring.** A ground ring encircling the building or structure, in direct contact with the earth, consisting of at least 6.0 m (20 ft) of bare copper conductor not smaller than 2 AWG.

**(5) Rod and Pipe Electrodes.** Rod and pipe electrodes shall not be less than 2.44 m (8 ft) in length and shall consist of the following materials.

- (a) Grounding electrodes of pipe or conduit shall not be smaller than metric designator 21 (trade size ¾) and,

where of steel, shall have the outer surface galvanized or otherwise metal-coated for corrosion protection.

(b) **Rod-type grounding electrodes** of stainless steel and copper or zinc coated steel shall be at least 15.87 mm ( $\frac{5}{8}$  in.) in diameter, unless listed.

(6) **Other Listed Electrodes.** Other listed grounding electrodes shall be permitted.

(7) **Plate Electrodes.** Each plate electrode shall expose not less than 0.186 m<sup>2</sup> (2 ft<sup>2</sup>) of surface to exterior soil. Electrodes of bare or conductively coated iron or steel plates shall be at least 6.4 mm ( $\frac{1}{4}$  in.) in thickness. Solid, uncoated electrodes of nonferrous metal shall be at least 1.5 mm (0.06 in.) in thickness.

(8) **Other Local Metal Underground Systems or Structures.** Other local metal underground systems or structures such as piping systems, underground tanks, and underground metal well casings that are not bonded to a metal water pipe.

(B) **Not Permitted for Use as Grounding Electrodes.** The following systems and materials shall not be used as grounding electrodes:

- (1) Metal underground gas piping systems
- (2) Aluminum

Informational Note: See 250.104(B) for bonding requirements of gas piping.

## 250.53 Grounding Electrode System Installation

Informational Note: See 547.9 and 547.10 for special grounding and bonding requirements for agricultural buildings.

(A) **Rod, Pipe, and Plate Electrodes.** Rod, pipe, and plate electrodes shall meet the requirements of 250.53(A)(1) through (A)(3).

(1) **Below Permanent Moisture Level.** If practicable, rod, pipe, and plate electrodes shall be embedded below permanent moisture level. Rod, pipe, and plate electrodes shall be free from nonconductive coatings such as paint or enamel.

(2) **Supplemental Electrode Required.** A single rod, pipe, or plate electrode shall be supplemented by an additional electrode of a type specified in 250.52(A)(2) through (A)(8). The supplemental electrode shall be permitted to be bonded to one of the following:

- (1) Rod, pipe, or plate electrode
- (2) Grounding electrode conductor
- (3) Grounded service-entrance conductor

- (4) Nonflexible grounded service raceway
- (5) Any grounded service enclosure

*Exception: If a single rod, pipe, or plate grounding electrode has a resistance to earth of 25 ohms or less, the supplemental electrode shall not be required.*

(3) **Supplemental Electrode.** If multiple rod, pipe, or plate electrodes are installed to meet the requirements of this section, they shall not be less than 1.8 m (6 ft) apart.

Informational Note: The paralleling efficiency of rods is increased by spacing them twice the length of the longest rod.

The spacing requirement in 250.53(A)(3) for multiple auxiliary rod, pipe, or plate electrodes is illustrated in Exhibit 250.24. The direct-buried clamps shown in Exhibit 250.24 are required to be listed for underground installation per 250.70.

**EXHIBIT 250.24** The 6 ft spacing between electrodes required by 250.53(B) and 250.56.

There are several methods available to measure the resistance to ground of a rod, pipe, or plate electrode in order to verify compliance with 250.53(A)(2), Exception. Exhibit 250.25 illustrates one method of determining the ground resistance of a rod type electrode in which a ground tester is used to measure the “fall of potential” between the rod being tested and the reference rod (stake) connected to the “P<sub>1</sub>” or

**EXHIBIT 250.25** The resistance to ground of a ground rod being measured using a fall of potential ground tester. The clamp-on tester is another method of determining the earth resistance of a grounding electrode.

“P<sub>2</sub>” terminal of the tester. The clamp-on ground resistance tester is a simpler method of testing the earth resistance of a grounding electrode, as it does not involve the use of reference electrodes to perform the earth resistance test.

**(B) Electrode Spacing.** Where more than one of the electrodes of the type specified in 250.52(A)(5) or (A)(7) are used, each electrode of one grounding system (including that used for strike termination devices) shall not be less than 1.83 m (6 ft) from any other electrode of another grounding system. Two or more grounding electrodes that are bonded together shall be considered a single grounding electrode system.

**(C) Bonding Jumper.** The bonding jumper(s) used to connect the grounding electrodes together to form the grounding electrode system shall be installed in accordance with 250.64(A), (B), and (E), shall be sized in accordance with 250.66, and shall be connected in the manner specified in 250.70.

**(D) Metal Underground Water Pipe.** If used as a grounding electrode, metal underground water pipe shall meet the requirements of 250.53(D)(1) and (D)(2).

**(1) Continuity.** Continuity of the grounding path or the bonding connection to interior piping shall not rely on water meters or filtering devices and similar equipment.

**(2) Supplemental Electrode Required.** A metal underground water pipe shall be supplemented by an additional electrode of a type specified in 250.52(A)(2) through (A)(8). If the supplemental electrode is of the rod, pipe, or plate type, it shall comply with 250.53(A). The supplemental electrode shall be bonded to one of the following:

- (1) Grounding electrode conductor
- (2) Grounded service-entrance conductor
- (3) Nonflexible grounded service raceway
- (4) Any grounded service enclosure
- (5) As provided by 250.32(B)

*Exception: The supplemental electrode shall be permitted to be bonded to the interior metal water piping at any convenient point as specified in 250.68(C)(1), Exception.*

Section 250.53(D)(2) specifically requires that rod, pipe, or plate electrodes used to supplement metal water piping be installed in accordance with 250.53(A). This requirement clarifies that the supplemental electrode system must be installed as if it were the sole grounding electrode for the system. As specified in the exception to 250.53(A)(2), if a single rod, pipe, or plate electrode has a resistance to earth of 25 ohms or less, it is not necessary to supplement that electrode with one of the types from 250.52(A)(2) through (A)(8). In other words, a single rod, pipe, or plate electrode being used to supplement a metal underground water pipe type electrode is itself required to be provided with a supplemental electrode unless the condition of 250.53(A)(2) Exception can be met. One of the permitted methods of bonding a supplemental grounding electrode conductor to the grounding electrode system is to connect it to the grounded service enclosure.

The requirement to supplement the metal water pipe is based on the practice of using a plastic pipe for replacement when the original metal water pipe fails. This type of replacement leaves the system without a grounding electrode unless a supplemental electrode is provided.

**(E) Supplemental Electrode Bonding Connection Size.** Where the supplemental electrode is a rod, pipe, or plate electrode, that portion of the bonding jumper that is the sole connection to the supplemental grounding electrode shall not be required to be larger than 6 AWG copper wire or 4 AWG aluminum wire.

Section 250.53(E) correlates with 250.52(A)(5) or (A)(7) and with 250.66(A). For example, if a metal underground water pipe or the metal frame of the building or structure is used as the grounding electrode or as part of the grounding electrode system, Table 250.66 must be used for sizing the

grounding electrode conductor. The size of the grounding electrode conductor or bonding jumper for ground rod or pipe or for plate electrodes between the service equipment and the electrodes is not required to be larger than 6 AWG copper or 4 AWG aluminum.

**(F) Ground Ring.** The ground ring shall be buried at a depth below the earth's surface of not less than 750 mm (30 in.).

**(G) Rod and Pipe Electrodes.** The electrode shall be installed such that at least 2.44 m (8 ft) of length is in contact with the soil. It shall be driven to a depth of not less than 2.44 m (8 ft) except that, where rock bottom is encountered, the electrode shall be driven at an oblique angle not to exceed 45 degrees from the vertical or, where rock bottom is encountered at an angle up to 45 degrees, the electrode shall be permitted to be buried in a trench that is at least 750 mm (30 in.) deep. The upper end of the electrode shall be flush with or below ground level unless the aboveground end and the grounding electrode conductor attachment are protected against physical damage as specified in 250.10.

Section 250.53(G) requires that all rod and pipe electrodes have at least 8 ft of length in contact with the soil, regardless of rock bottom. Where rock bottom is encountered, the electrodes must be either driven at not more than a 45-degree angle or buried in a 2½-ft-deep trench. Driving the rod at an angle is permitted only if it is not possible to drive the rod vertically to obtain at least 8 ft of earth contact. Burying the ground rod is permitted only if it is not possible to drive the rod vertically or at an angle. Exhibit 250.26 illustrates these requirements.

Section 250.70 requires ground clamps used on buried electrodes to be listed for direct earth burial. Ground clamps installed above ground must be protected where subject to physical damage per 250.53(G).

**(H) Plate Electrode.** Plate electrodes shall be installed not less than 750 mm (30 in.) below the surface of the earth.

## 250.54 Auxiliary Grounding Electrodes

One or more grounding electrodes shall be permitted to be connected to the equipment grounding conductors specified in 250.118 and shall not be required to comply with the electrode bonding requirements of 250.50 or 250.53(C) or the resistance requirements of 250.53(A)(2) Exception, but the earth shall not be used as an effective ground-fault current path as specified in 250.4(A)(5) and 250.4(B)(4).

**EXHIBIT 250.26** Installation requirements for rod and pipe electrodes as specified by 250.53(G).

Grounding electrodes, such as ground rods, that are connected to equipment are not permitted by 250.54 to be used in lieu of the equipment grounding conductor, but they may be used to provide a local earth reference connection at electrical equipment locations. For example, grounding electrodes may be used for lightning protection or to establish a reference to ground in the area of electrically operated equipment. Sections 250.4(A)(5) and 250.4(B)(4) also specify that the earth not be used as the sole equipment grounding conductor or effective (ground) fault current path. Auxiliary grounding electrodes are not required to be incorporated into the grounding electrode system for the service or other source of electrical supply.

## 250.58 Common Grounding Electrode

Where an ac system is connected to a grounding electrode in or at a building or structure, the same electrode shall be used to ground conductor enclosures and equipment in or on that building or structure. Where separate services, feeders, or branch circuits supply a building and are required to be connected to a grounding electrode(s), the same grounding electrode(s) shall be used.

Two or more grounding electrodes that are bonded together shall be considered as a single grounding electrode system in this sense.

### 250.60 Use of Strike Termination Devices

Conductors and driven pipes, rods, or plate electrodes used for grounding strike termination devices shall not be used in lieu of the grounding electrodes required by 250.50 for grounding wiring systems and equipment. This provision shall not prohibit the required bonding together of grounding electrodes of different systems.

Informational Note No. 1: See 250.106 for spacing from strike termination devices. See 800.100(D), 810.21(J), and 820.100(D) for bonding of electrodes.

Informational Note No. 2: Bonding together of all separate grounding electrodes will limit potential differences between them and between their associated wiring systems.

### 250.62 Grounding Electrode Conductor Material

The grounding electrode conductor shall be of copper, aluminum, or copper-clad aluminum. The material selected shall be resistant to any corrosive condition existing at the installation or shall be protected against corrosion. The conductor shall be solid or stranded, insulated, covered, or bare.

### 250.64 Grounding Electrode Conductor Installation

Grounding electrode conductors at the service, at each building or structure where supplied by a feeder(s) or branch circuit(s), or at a separately derived system shall be installed as specified in 250.64(A) through (F).

**(A) Aluminum or Copper-Clad Aluminum Conductors.** Bare aluminum or copper-clad aluminum grounding electrode conductors shall not be used where in direct contact with masonry or the earth or where subject to corrosive conditions. Where used outside, aluminum or copper-clad aluminum grounding electrode conductors shall not be terminated within 450 mm (18 in.) of the earth.

**(B) Securing and Protection Against Physical Damage.** Where exposed, a grounding electrode conductor or its enclosure shall be securely fastened to the surface on which it is carried. Grounding electrode conductors shall be permitted to be installed on or through framing members. A 4 AWG or larger copper or aluminum grounding electrode conductor shall be protected if exposed to physical damage. A 6 AWG grounding electrode conductor that is free from exposure to physical damage shall be permitted to be run along the surface of the building construction without metal covering or protection if it is securely fastened to the construction; otherwise, it shall be protected in rigid metal conduit (RMC), intermediate metal conduit (IMC), rigid polyvinyl chloride conduit (PVC), reinforced thermosetting resin conduit (RTRC), electrical metallic tubing (EMT), or

cable armor. Grounding electrode conductors smaller than 6 AWG shall be protected in RMC, IMC, PVC, RTRC, EMT, or cable armor.

Section 250.64(B) contains the provisions for securing and protecting grounding electrode conductors. This section specifically permits grounding electrode conductors to be installed through and on framing members; this includes running it exposed or concealed through bored or punched holes in studs, joists, or rafters. See 250.64(E) for additional information on situations in which metal raceways enclose the grounding electrode conductor. Also see the commentary following 250.64(E) and the illustration that accompanies that commentary, Exhibit 250.28, for installation requirements for metal raceways used to install and physically protect the grounding electrode conductor(s).

**(C) Continuous.** Except as provided in 250.30(A)(5) and (A)(6), 250.30(B)(1), and 250.68(C), grounding electrode conductor(s) shall be installed in one continuous length without a splice or joint. If necessary, splices or connections shall be made as permitted in (1) through (4):

- (1) Splicing of the wire-type grounding electrode conductor shall be permitted only by irreversible compression-type connectors listed as grounding and bonding equipment or by the exothermic welding process.
- (2) Sections of busbars shall be permitted to be connected together to form a grounding electrode conductor.
- (3) Bolted, riveted, or welded connections of structural metal frames of buildings or structures.
- (4) Threaded, welded, brazed, soldered or bolted-flange connections of metal water piping.

Conditions such as those encountered as part of a building remodeling project or with the replacement of existing electrical equipment may necessitate splicing the grounding electrode conductor. Section 250.64(C)(1) contains the permitted means by which the splice can be made. The two permitted methods are considered to be an extremely permanent connection and provide the intended grounding electrode conductor continuity. Section 250.64(C)(2) recognizes the normal bolted connections between sections of busbar that are joined to form the grounding electrode conductor. The connections specified in (3) and (4) correlate with the permission in 250.68(C) to use metal water piping and the structural metal frame of a building as a grounding electrode conductor or as a conductor used to interconnect other grounding electrodes.

**(D) Service with Multiple Disconnecting Means Enclosures.** If a service consists of more than a single enclosure

as permitted in 230.71(A), grounding electrode connections shall be made in accordance with 250.64(D)(1), (D)(2), or (D)(3).

### (1) Common Grounding Electrode Conductor and Taps

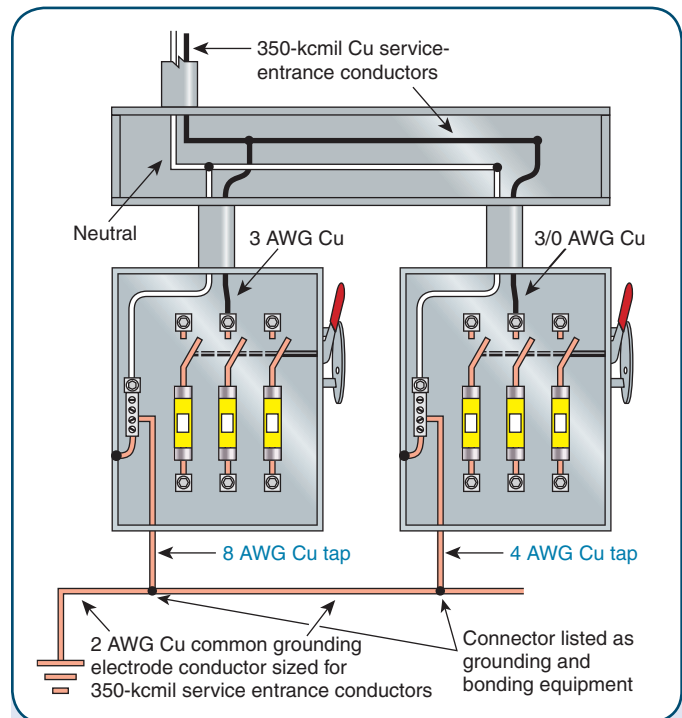

A common grounding electrode conductor and grounding electrode conductor taps shall be installed. The common grounding electrode conductor shall be sized in accordance with 250.66, based on the sum of the circular mil area of the largest ungrounded service-entrance conductor(s). If the service-entrance conductors connect directly to a service drop or service lateral, the common grounding electrode conductor shall be sized in accordance with Table 250.66, Note 1.

A grounding electrode conductor tap shall extend to the inside of each service disconnecting means enclosure. The grounding electrode conductor taps shall be sized in accordance with 250.66 for the largest service-entrance conductor serving the individual enclosure. The tap conductors shall be connected to the common grounding electrode conductor by one of the following methods in such a manner that the common grounding electrode conductor remains without a splice or joint:

- (1) Exothermic welding.
- (2) Connectors listed as grounding and bonding equipment.
- (3) Connections to an aluminum or copper busbar not less than 6 mm × 50 mm (¼ in. × 2 in.). The busbar shall be securely fastened and shall be installed in an accessible location. Connections shall be made by a listed connector or by the exothermic welding process. If aluminum busbars are used, the installation shall comply with 250.64(A).

The requirements for grounding electrode (tap) conductors given in 250.64(D)(1) include the methods for sizing and installing taps. They are sized using Table 250.66 based on the size of the largest phase conductor serving each service disconnecting means enclosure. The common grounding electrode conductor from which the taps are made is sized from Table 250.66 based on the sum of the cross-sectional areas of the largest ungrounded service-entrance conductors or equivalent cross-sectional area for parallel conductors that supply the multiple service disconnecting means.

As illustrated in Exhibit 250.27, the tap method permitted by this section eliminates the difficulties found in looping grounding electrode conductors from one enclosure to another. The 2 AWG grounding electrode conductor (based on the 350-kcmil ungrounded conductor) shown in Exhibit 250.27 is required to be installed without a splice or joint, except as permitted in 250.64(C), and the 8 AWG and 4 AWG taps are sized from Table 250.66 based on the size of the ungrounded conductor serving the respective service dis-

**EXHIBIT 250.27** The tap method of connecting the grounding electrode conductor to multiple service disconnecting means enclosures.

connecting means. This section recognizes exothermic welding, connectors specifically listed for grounding and bonding, and connections to an accessible copper or aluminum busbar with minimum dimensions of ¼ in. thick by 2 in. wide as acceptable methods to connect the taps to the common grounding electrode conductor.

**(2) Individual Grounding Electrode Conductors.** A grounding electrode conductor shall be connected between the grounded conductor in each service equipment disconnecting means enclosure and the grounding electrode system. Each grounding electrode conductor shall be sized in accordance with 250.66 based on the service-entrance conductor(s) supplying the individual service disconnecting means.

**(3) Common Location.** A grounding electrode conductor shall be connected to the grounded service conductor(s) in a wireway or other accessible enclosure on the supply side of the service disconnecting means. The connection shall be made with exothermic welding or a connector listed as grounding and bonding equipment. The grounding electrode conductor shall be sized in accordance with 250.66 based on the service-entrance conductor(s) at the common location where the connection is made.

**(E) Enclosures for Grounding Electrode Conductors.**

Ferrous metal enclosures for grounding electrode conductors shall be electrically continuous from the point of attachment to cabinets or equipment to the grounding electrode and shall be securely fastened to the ground clamp or fitting. Nonferrous metal enclosures shall not be required to be electrically continuous. Ferrous metal enclosures that are not physically continuous from cabinets or equipment to the grounding electrode shall be made electrically continuous by bonding each end of the raceway or enclosure to the grounding electrode conductor. Bonding methods in compliance with 250.92(B) for installations at service equipment locations and with 250.92(B)(2) through (B)(4) for other than service equipment locations shall apply at each end and to all intervening ferrous raceways, boxes, and enclosures between the cabinets or equipment and the grounding electrode. The bonding jumper for a grounding electrode conductor raceway or cable armor shall be the same size as, or larger than, the enclosed grounding electrode conductor. If a raceway is used as protection for a grounding electrode conductor, the installation shall comply with the requirements of the appropriate raceway article.

Bonding jumpers installed to ensure the electrical continuity of ferrous metal enclosures must be sized in accordance with 250.102(C). Exhibit 250.28 shows the required bonding of a ferrous metal raceway to the grounding electrode conductor at both ends of the raceway to ensure that the raceway and conductor are in parallel. These bonding connections are necessary so that the ferrous raceway does not create an inductive choke on the grounding electrode conductor.

**(F) Installation to Electrode(s).** Grounding electrode conductor(s) and bonding jumpers interconnecting grounding electrodes shall be installed in accordance with (1), (2), or (3). The grounding electrode conductor shall be sized for the largest grounding electrode conductor required among all the electrodes connected to it.

- (1) The grounding electrode conductor shall be permitted to be run to any convenient grounding electrode available in the grounding electrode system where the other electrode(s), if any, is connected by bonding jumpers that are installed in accordance with 250.53(C).
- (2) Grounding electrode conductor(s) shall be permitted to be run to one or more grounding electrode(s) individually.
- (3) Bonding jumper(s) from grounding electrode(s) shall be permitted to be connected to an aluminum or copper busbar not less than 6 mm × 50 mm (¼ in. × 2 in.). The busbar shall be securely fastened and shall be installed in an accessible location. Connections shall be made by

**EXHIBIT 250.28** Bonding of a metal raceway that contains a grounding electrode conductor to the conductor at both ends, as required by 250.64(E).

a listed connector or by the exothermic welding process. The grounding electrode conductor shall be permitted to be run to the busbar. Where aluminum busbars are used, the installation shall comply with 250.64(A).

Exhibit 250.29 illustrates a grounding electrode system. The single grounding electrode conductor is permitted to run “to any convenient grounding electrode available,” per 250.64(F)(1), and the other electrodes are connected together using bonding jumpers sized in accordance with 250.53(C), which references 250.66. A permitted alternative to installing the grounding electrode conductor to an electrode is to run it to a busbar used as a connection point for bonding jumpers from multiple electrodes that form the grounding electrode system.

A securely fastened section of copper or aluminum busbar, not less than ¼ in. thick by 2 in. wide (the length can be whatever is necessary to make the connections), is permitted as a connection point for multiple grounding electrode conductors or for bonding jumpers used to connect multiple grounding electrodes together. The connection of the wire to the busbar must be via an exothermic weld or by a listed connector that is attached to the busbar using the typical bolted connection. A fully sized grounding electrode con-

**EXHIBIT 250.29** An example of running the grounding electrode conductor to any convenient electrode available as well as bonding all electrodes that are present at a building or structure together to form the grounding electrode system required by 250.50.

ductor, sized in accordance with 250.66 for the largest electrode used, is permitted to be run to the busbar from the point at which it is connected to the grounded or ungrounded system equipment.

250.66 Size of Alternating-Current Grounding Electrode Conductor

The size of the grounding electrode conductor at the service, at each building or structure where supplied by a feeder(s) or branch circuit(s), or at a separately derived system of a grounded or ungrounded ac system shall not be less than given in Table 250.66, except as permitted in 250.66(A) through (C).

Informational Note: See 250.24(C) for size of ac system conductor brought to service equipment.

Calculation Example

Apply the sizing requirements in Table 250.66 to Exhibit 250.30 to determine the size of the grounding electrode conductor that is tapped for grounding connections in the two enclosures.

**TABLE 250.66** Grounding Electrode Conductor for Alternating-Current Systems

Size of Largest Ungrounded Service-Entrance Conductor or Equivalent Area for Parallel Conductors <sup>a</sup> (AWG/kcmil)		Size of Grounding Electrode Conductor (AWG/kcmil)	
Copper	Aluminum or Copper-Clad Aluminum	Copper	Aluminum or Copper-Clad Aluminum <sup>b</sup>
2 or smaller	1/0 or smaller	8	6
1 or 1/0	2/0 or 3/0	6	4
2/0 or 3/0	4/0 or 250	4	2
Over 3/0 through 350	Over 250 through 500	2	1/0
Over 350 through 600	Over 500 through 900	1/0	3/0
Over 600 through 1100	Over 900 through 1750	2/0	4/0
Over 1100	Over 1750	3/0	250

Notes:

- 1. Where multiple sets of service-entrance conductors are used as permitted in 230.40, Exception No. 2, the equivalent size of the largest service-entrance conductor shall be determined by the largest sum of the areas of the corresponding conductors of each set.
- 2. Where there are no service-entrance conductors, the grounding electrode conductor size shall be determined by the equivalent size of the largest service-entrance conductor required for the load to be served.

<sup>a</sup>This table also applies to the derived conductors of separately derived ac systems.

<sup>b</sup>See installation restrictions in 250.64(A).

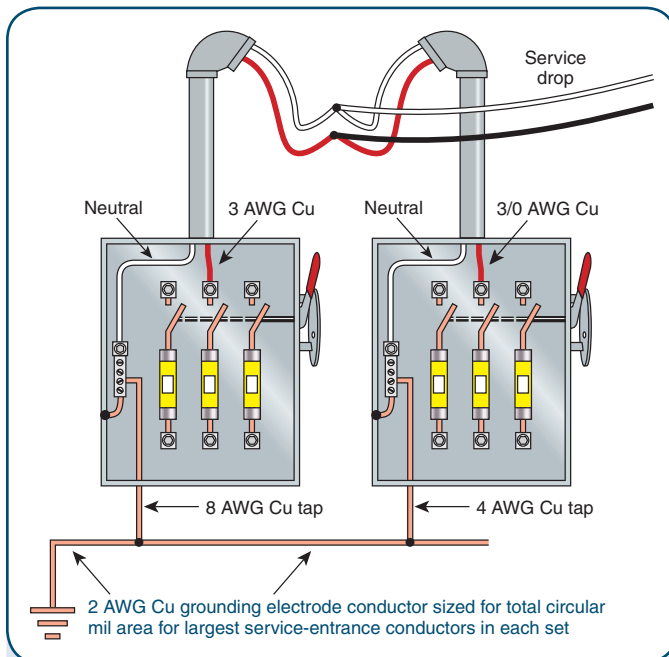

Solution

STEP 1. Using Table 8 in Chapter 9, calculate the total circular mil area by adding the circular mil areas for the largest ungrounded conductor from each set of service-entrance conductors:

Set #1: 3 AWG = 52,620 circular mils  
Set #2: 3/0 AWG = 167,800 mils  
Total area = 220,420 circular mils or 220.42 kcmil

STEP 2. Use Table 250.66 to size the grounding electrode conductor. According to the fourth row, “Over 3/0 through 350,” the size should be 2 AWG copper or 1/0 AWG aluminum.

The taps to the grounding electrode conductor from each service disconnecting means enclosure in Exhibit 250.30 are sized from Table 250.66 based on the size of the service-entrance conductors supplying the individual enclosures.

**EXHIBIT 250.30** A grounding electrode conductor with multiple sets of service conductors, sized according to Table 250.66, Note 1.

**(A) Connections to Rod, Pipe, or Plate Electrodes.**

Where the grounding electrode conductor is connected to rod, pipe, or plate electrodes as permitted in 250.52(A)(5) or (A)(7), that portion of the conductor that is the sole connection to the grounding electrode shall not be required to be larger than 6 AWG copper wire or 4 AWG aluminum wire.

**(B) Connections to Concrete-Encased Electrodes.** Where the grounding electrode conductor is connected to a concrete-encased electrode as permitted in 250.52(A)(3), that portion of the conductor that is the sole connection to the grounding electrode shall not be required to be larger than 4 AWG copper wire.

**(C) Connections to Ground Rings.** Where the grounding electrode conductor is connected to a ground ring as permitted in 250.52(A)(4), that portion of the conductor that is the sole connection to the grounding electrode shall not be required to be larger than the conductor used for the ground ring.

Exhibit 250.31 illustrates a grounding electrode conductor (GEC) installed from service equipment or a separately derived system to a water pipe grounding electrode. The grounding electrode conductor between the service equipment or separately derived system and the water pipe is required to be a full-size conductor based on the size of the

**EXHIBIT 250.31** Grounding electrode conductor and bonding jumpers sized in accordance with 250.66 for a service supplied by 3/0 AWG copper ungrounded conductors.

ungrounded supply conductors, per Table 250.66. The bonding jumpers that connect the other grounding electrodes together are also sized using 250.53(C), which refers to 250.66 (Table 250.66), but they are not necessarily required to be full-sized if they are covered by 250.66(A), (B), or (C). In this illustration, the size of the grounding electrode conductor and bonding jumpers is dependent on which electrode the grounding electrode conductor connects to. For example, if the grounding electrode conductor from the service equipment is run to the ground rod first and then to the water pipe, the GEC to the ground rod is required to be full size per Table 250.66, and in this illustration, it can be no smaller than a 4 AWG copper conductor. Exhibit 250.31 is not intended to show a mandatory physical routing and connection order of the bonding jumpers and the grounding electrode conductor as the *Code* does not specify an order or hierarchy for these connections. The sizes for the bonding jumpers to the ground rod and the concrete-encased electrode shown in Exhibit 250.31 are the maximum sizes required by the *Code* based on 250.66. The use of bonding jumpers or grounding electrode conductors larger than required by 250.66 is not prohibited.

## 250.68 Grounding Electrode Conductor and Bonding Jumper Connection to Grounding Electrodes

The connection of a grounding electrode conductor at the service, at each building or structure where supplied by a

feeder(s) or branch circuit(s), or at a separately derived system and associated bonding jumper(s) shall be made as specified 250.68(A) through (C).

**(A) Accessibility.** All mechanical elements used to terminate a grounding electrode conductor or bonding jumper to a grounding electrode shall be accessible.

*Exception No. 1: An encased or buried connection to a concrete-encased, driven, or buried grounding electrode shall not be required to be accessible.*

*Exception No. 2: Exothermic or irreversible compression connections used at terminations, together with the mechanical means used to attach such terminations to fireproofed structural metal whether or not the mechanical means is reversible, shall not be required to be accessible.*

Where the exposed portion of an encased, driven, or buried electrode is used for the termination of a grounding electrode conductor, the terminations must be accessible per 250.68(A). However, if the connection is buried or encased, Exception No. 1 does not require the terminations to be accessible. Ground clamps and other connectors suitable for use where buried in earth or embedded in concrete must be listed for such use per 250.70, and indication of this listing is either by a marking on the connector or by a tag attached to the connector. See Exhibits 250.22 and 250.24 for illustrations of encased and buried electrodes. Exception No. 2 permits connections, including the mechanical attachment of a compression lug to structural steel, to be encapsulated by fireproofing material. Because these connections are not required to be accessible for inspection, the method of connection to the structural member must be either an exothermic weld or an irreversible compression connector. This exception recognizes the importance of maintaining the integrity of the structural fireproofing.

**(B) Effective Grounding Path.** The connection of a grounding electrode conductor or bonding jumper to a grounding electrode shall be made in a manner that will ensure an effective grounding path. Where necessary to ensure the grounding path for a metal piping system used as a grounding electrode, bonding shall be provided around insulated joints and around any equipment likely to be disconnected for repairs or replacement. Bonding jumpers shall be of sufficient length to permit removal of such equipment while retaining the integrity of the grounding path.

Examples of equipment likely to be disconnected for repairs or replacement are water meters and water filter systems. Because of reports on the disconnection of bonding jumpers

in order to facilitate removal or reinstallation of a water meter or filter cartridge, this section specifies that the length of the bonding jumper has to permit removal of such equipment without disconnecting or otherwise interrupting the bonding jumper.

**(C) Metallic Water Pipe and Structural Metal.** Grounding electrode conductors and bonding jumpers shall be permitted to be connected at the following locations and used to extend the connection to an electrode(s):

- (1) Interior metal water piping located not more than 1.52 m (5 ft) from the point of entrance to the building shall be permitted to be used as a conductor to interconnect electrodes that are part of the grounding electrode system.

*Exception: In industrial, commercial, and institutional buildings or structures, if conditions of maintenance and supervision ensure that only qualified persons service the installation, interior metal water piping located more than 1.52 m (5 ft) from the point of entrance to the building shall be permitted as a bonding conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor, if the entire length, other than short sections passing perpendicularly through walls, floors, or ceilings, of the interior metal water pipe that is being used for the conductor is exposed.*

- (2) The structural frame of a building that is directly connected to a grounding electrode as specified in 250.52(A)(2) or 250.68(C)(2)(a), (b), or (c) shall be permitted as a bonding conductor to interconnect electrodes that are part of the grounding electrode system, or as a grounding electrode conductor.
  - a. By connecting the structural metal frame to the reinforcing bars of a concrete-encased electrode, as provided in 250.52(A)(3), or ground ring as provided in 250.52(A)(4)
  - b. By bonding the structural metal frame to one or more of the grounding electrodes, as specified in 250.52(A)(5) or (A)(7), that comply with (2)
  - c. By other approved means of establishing a connection to earth

The requirement in 250.68(C)(1) limits grounding and bonding connections to occurring only within the first 5 ft of where the piping enters a building or structure because of concerns that the use of nonmetallic piping or fittings could interrupt the electrical continuity of the metal water piping.

The piping at this point is not a grounding electrode [only the underground portion is an electrode per 250.52(A)(1)].

Rather, it is used to extend grounding and bonding conductor connections to the grounding electrode. The exception permits connections to occur beyond the first 5 ft and at that point the water piping is considered as a conductor used for bonding grounding electrodes together or as the actual grounding electrode conductor. All of the conditions of the exception, including the use of qualified persons to service the water piping system, must be met in order to extend the permitted point of connection beyond the first 5 ft of where the piping enters the building.

Similarly, 250.68(C)(2) covers the structural steel within a building and establishes the specific conditions under which the structural steel can be used as a bonding conductor or as a grounding electrode conductor. The structural metal frame of a building is not a grounding electrode unless it is connected to earth by one or more of the means specified in 250.52(A)(2). The required bonding of metal water piping and metal structural frames is covered in 250.104(A) and (C).

### 250.70 Methods of Grounding and Bonding Conductor Connection to Electrodes

The grounding or bonding conductor shall be connected to the grounding electrode by exothermic welding, listed lugs, listed pressure connectors, listed clamps, or other listed means. Connections depending on solder shall not be used. Ground clamps shall be listed for the materials of the grounding electrode and the grounding electrode conductor and, where used on pipe, rod, or other buried electrodes, shall also be listed for direct soil burial or concrete encasement. Not more than one conductor shall be connected to the grounding electrode by a single clamp or fitting unless the clamp or fitting is listed for multiple conductors. One of the following methods shall be used:

- (1) A pipe fitting, pipe plug, or other approved device screwed into a pipe or pipe fitting
- (2) A listed bolted clamp of cast bronze or brass, or plain or malleable iron
- (3) For indoor communications purposes only, a listed sheet metal strap-type ground clamp having a rigid metal base that seats on the electrode and having a strap of such material and dimensions that it is not likely to stretch during or after installation
- (4) An equally substantial approved means

The methods for connecting the grounding or bonding conductor to a grounding electrode(s) are specified in 250.70(1) through (4). Where a ground clamp is used and terminates, for example, on a galvanized water pipe, the clamp must be of a material compatible with steel, to prevent galvanic corrosion. The same requirement applies to ground clamps used with

grounding electrodes made of other materials such as copper or steel reinforcing rods or bars. Additionally the clamp must be also be compatible with the material for the grounding electrode conductor and if buried, listed for that use.

Exhibit 250.32 shows a listed water pipe ground clamp generally used with 8 AWG through 4 AWG grounding electrode conductors. Exothermic weld kits acceptable for this purpose are commercially available.

Exhibit 250.33 shows a listed U-bolt ground clamp. These clamps are available for all pipe sizes and all ground-

**EXHIBIT 250.32** An application of a listed ground clamp.

**EXHIBIT 250.33** An application of a listed U-bolt ground clamp.

ing electrode conductor sizes. Where grounding electrode conductors are run in conduit, conduit hubs may be bolted to the threaded portion of the U-bolt.

## IV. Enclosure, Raceway, and Service Cable Connections

### 250.80 Service Raceways and Enclosures

Metal enclosures and raceways for service conductors and equipment shall be connected to the grounded system conductor if the electrical system is grounded or to the grounding electrode conductor for electrical systems that are not grounded.

*Exception: A metal elbow that is installed in an underground nonmetallic raceway and is isolated from possible contact by a minimum cover of 450 mm (18 in.) to any part of the elbow shall not be required to be connected to the grounded system conductor or grounding electrode conductor.*

The exception to 250.80 recognizes that metal sweep elbows are often installed in underground installations of nonmetallic conduit. The metal elbows are installed because nonmetallic elbows can be damaged from the friction caused by taut conductor pull lines or ropes rubbing against the interior of the elbow throat. The elbows are isolated from physical contact by burying the entire elbow at a depth not less than 18 in. below grade. This exception applies where isolated metal elbows are used in a service raceway installation and 250.86, Exception No. 3 applies to raceways containing other than service conductors. See Exhibit 250.34 for an example of an application of this provision.

### 250.84 Underground Service Cable or Raceway

**(A) Underground Service Cable.** The sheath or armor of a continuous underground metal-sheathed or armored service cable system that is connected to the grounded system conductor on the supply side shall not be required to be connected to the grounded system conductor at the building or structure. The sheath or armor shall be permitted to be insulated from the interior metal raceway or piping.

**(B) Underground Service Raceway Containing Cable.** An underground metal service raceway that contains a metal-sheathed or armored cable connected to the grounded system conductor shall not be required to be connected to the grounded system conductor at the building or structure. The sheath or armor shall be permitted to be insulated from the interior metal raceway or piping.

**EXHIBIT 250.34** An application of 250.80, Exception, which permits the metal elbows to be ungrounded, provided they are isolated from contact by a minimum cover of 18 in. to any part of the elbow.

### 250.86 Other Conductor Enclosures and Raceways

Except as permitted by 250.112(I), metal enclosures and raceways for other than service conductors shall be connected to the equipment grounding conductor.

*Exception No. 1: Metal enclosures and raceways for conductors added to existing installations of open wire, knob-and-tube wiring, and nonmetallic-sheathed cable shall not be required to be connected to the equipment grounding conductor where these enclosures or wiring methods comply with (1) through (4) as follows:*

- (1) Do not provide an equipment ground
- (2) Are in runs of less than 7.5 m (25 ft)
- (3) Are free from probable contact with ground, grounded metal, metal lath, or other conductive material
- (4) Are guarded against contact by persons

*Exception No. 2: Short sections of metal enclosures or raceways used to provide support or protection of cable assemblies from physical damage shall not be required to be connected to the equipment grounding conductor.*

*Exception No. 3: A metal elbow shall not be required to be connected to the equipment grounding conductor where it is installed in a run of nonmetallic raceway and is isolated from possible contact by a minimum cover of 450 mm (18 in.) to any part of the elbow or is encased in not less than 50 mm (2 in.) of concrete.*

Section 250.86 requires grounding, bonding, and ensured electrical continuity of all enclosures and metal raceways.

Connectors, couplings, or other similar fittings that perform mechanical and electrical functions must ensure bonding and grounding continuity between the fitting, the metal raceway, and the enclosure. Metal enclosures must be grounded so that when a fault occurs between an ungrounded (hot) conductor and ground, the potential difference between the non-current-carrying parts of the electrical installation is minimized, thereby reducing the risk of shock.

## V. Bonding

### 250.90 General

Bonding shall be provided where necessary to ensure electrical continuity and the capacity to conduct safely any fault current likely to be imposed.

### 250.92 Services

**(A) Bonding of Equipment for Services.** The normally non-current-carrying metal parts of equipment indicated in 250.92(A)(1) and (A)(2) shall be bonded together.

- (1) All raceways, cable trays, cablebus framework, auxiliary gutters, or service cable armor or sheath that enclose, contain, or support service conductors, except as permitted in 250.80
- (2) All enclosures containing service conductors, including meter fittings, boxes, or the like, interposed in the service raceway or armor

**(B) Method of Bonding at the Service.** Bonding jumpers meeting the requirements of this article shall be used around impaired connections, such as reducing washers or oversized, concentric, or eccentric knockouts. Standard locknuts or bushings shall not be the only means for the bonding required by this section but shall be permitted to be installed to make a mechanical connection of the raceway(s).

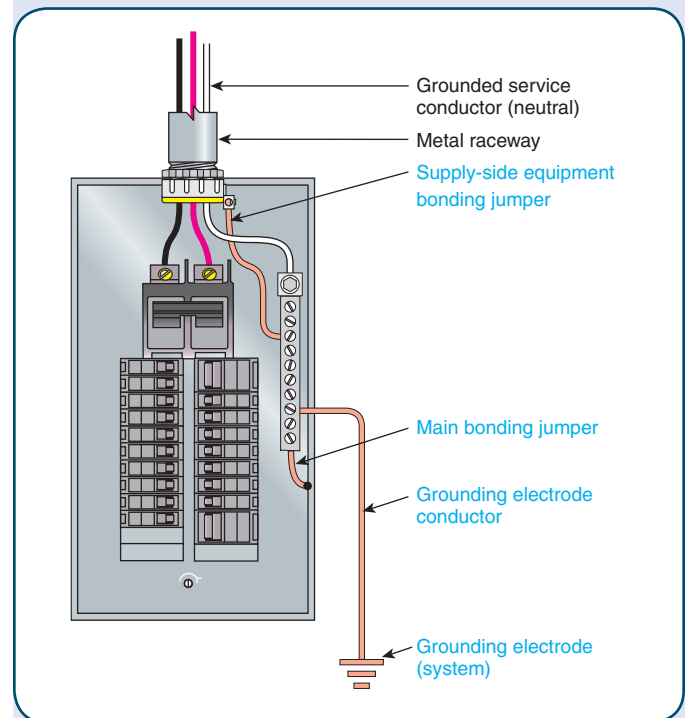

Standard locknuts, sealing locknuts, and metal bushings are not acceptable as the sole means for bonding a raceway or cable to an enclosure on the line side of the service disconnecting means regardless of the type of or condition of the knockout. For connections in which reducing washers are used and for knockouts that are concentric, eccentric, or oversized, electrical continuity has to be ensured through the use of a supply-side bonding jumper that connects the raceway to the enclosure. Oversized, concentric, and eccentric knockouts in service enclosures impede the bonding connections required by 250.92(B), and bonding jumpers are required to ensure that any bonding connection will provide a suitable path for the high levels of ground-fault current that is generally available on the line side of the service disconnecting means and overcurrent protective device. For the

same reason, standard locknuts and metal bushings that may be a suitable bonding connection at some locations on the load side of the service equipment are not considered to be a reliable bonding connection at this point in the electrical system and cannot be relied upon as the “sole” bonding connection. For further information on concentric and eccentric knockouts, see the commentary following the definition of *bonding jumper* in Article 100 and the example shown in Exhibit 100.4.

Electrical continuity at service equipment, service raceways, and service conductor enclosures shall be ensured by one of the following methods:

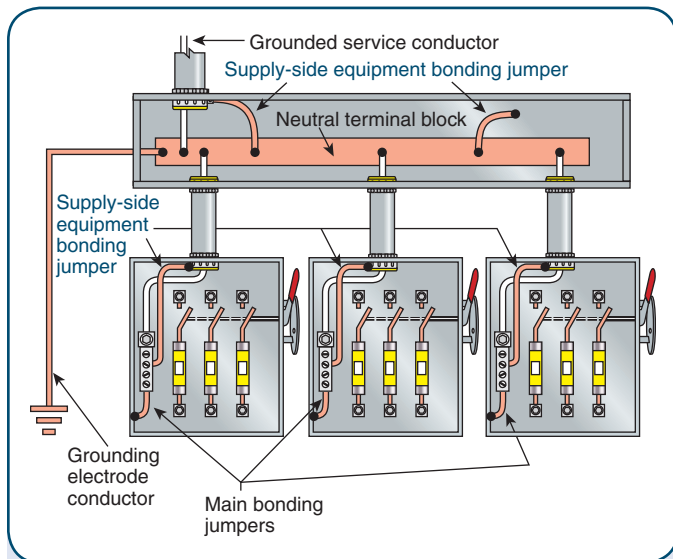

- (1) Bonding equipment to the grounded service conductor in a manner provided in 250.8

Exhibit 250.35 illustrates one acceptable grounding and bonding arrangement at a service having one disconnecting means. Exhibit 250.36 illustrates one acceptable grounding and bonding arrangement for a service with three disconnecting means as is permitted by 230.71(A). Section 250.24(C) specifies that the grounded service conductor must be run to each service disconnecting means and be bonded to the disconnecting means enclosure, as illustrated for the service with three disconnecting means in Exhibit 250.36. Section

**EXHIBIT 250.35** Grounding and bonding arrangement for a service with one disconnecting means.

**EXHIBIT 250.36** Grounding and bonding arrangement for a service with three disconnecting means.

250.92(B)(1) permits the bonding of service equipment enclosures to be accomplished by bonding the grounded service conductor to the enclosure.

- (2) Connections utilizing threaded couplings or threaded hubs on enclosures **if** made up wrenchtight
- (3) Threadless couplings and connectors **if** made up tight for metal raceways and metal-clad cables
- (4) Other listed devices, such as bonding-type locknuts, bushings, or bushings with bonding jumpers

Section 250.92(B)(4) specifies that listed bonding-type locknuts, bushings, or bushings with bonding jumpers are acceptable means for bonding raceways and cables to service equipment enclosures or other enclosures installed on the line side of the service equipment.

Bonding-type locknuts and grounding and bonding bushings for use with rigid or intermediate metal conduit are provided with means (usually one or more set screws that make positive contact with the conduit) for reliably bonding the bushing and the conduit on which it is threaded to the metal equipment enclosure or box.

Grounding bushings used with rigid or intermediate metal conduit or with tubing (EMT) fittings, such as those shown in Exhibits 250.37 and 250.38, have provisions for connecting a bonding jumper or have means provided by the manufacturer for use in mounting a wire connector. This type of bushing may also have means (usually one or more set screws) to reliably bond the bushing to the conduit. Exhibit 250.39 shows a listed bonding-type wedge lug used to

**EXHIBIT 250.37** Grounding bushings used to connect a copper bonding or grounding wire to conduits. (Courtesy of Thomas & Betts Corp.)

**EXHIBIT 250.38** A threaded grounding bushing with set screws used to ensure electrical and mechanical connection and a terminal for connection of a grounding conductor or bonding jumper. (Courtesy of Thomas & Betts Corp.)

connect a conduit to a box and provide the bonding connection required by 250.92(B).

## 250.94 Bonding for Other Systems

An intersystem bonding termination for connecting intersystem bonding conductors required for other systems shall be provided external to enclosures at the service equipment or metering equipment enclosure and at the disconnecting means for any additional buildings or structures. The inter-

**EXHIBIT 250.39** A grounding wedge lug used to provide an electrical connection between a conduit and a box. (Courtesy of Thomas & Betts Corp.)

system bonding termination shall comply with the following:

- (1) Be accessible for connection and inspection.
- (2) Consist of a set of terminals with the capacity for connection of not less than three intersystem bonding conductors.
- (3) Not interfere with opening the enclosure for a service, building or structure disconnecting means, or metering equipment.

For new installations, an external means for intersystem bonding connections is required to be provided at either the service equipment location, the metering equipment location, or at the disconnecting means located at a building or structure supplied by a feeder or branch circuit. *Intersystem* means that the electrical system and other premises systems such as optical fiber (Article 770), communications (Article 800), CATV (Article 820), and broadband systems (Articles 830 and 840) are bonded together to minimize the occurrence of potential differences in equipment in which multiple systems interface. Requirements covering the type of terminal permitted and the installation methods are specified in 250.94(1) through (6). Exhibit 250.40 is an example of an intersystem bonding termination that is to be installed and connected as specified in 250.94 (1) through (6). Exhibit 250.41 is another type of intersystem bonding connection that permits connection to the exterior of an equipment en-

**EXHIBIT 250.40** A listed intersystem bonding termination providing the required number of terminals (minimum of three) for connecting other building systems to the grounding system of the electrical power supply.

**EXHIBIT 250.41** A listed means for making intersystem bonding connections to a grounded meter socket enclosure. (Courtesy of Thomas & Betts Corp.)

closure as specified in 250.94(4) and also allows access to the equipment on which it is mounted in accordance with 250.94(3).

- (4) At the service equipment, be securely mounted and electrically connected to an enclosure for the service equipment, to the meter enclosure, or to an exposed nonflexible metallic service raceway, or be mounted at one of these enclosures and be connected to the enclosure or to the grounding electrode conductor with a minimum 6 AWG copper conductor
- (5) At the disconnecting means for a building or structure, be securely mounted and electrically connected to the metallic enclosure for the building or structure disconnecting means, or be mounted at the disconnecting means and be connected to the metallic enclosure or to the grounding electrode conductor with a minimum 6 AWG copper conductor.
- (6) The terminals shall be listed as grounding and bonding equipment.

*Exception: In existing buildings or structures where any of the intersystem bonding and grounding electrode conductors required by 770.100(B)(2), 800.100(B)(2), 810.21(F)(2), 820.100(B)(2), and 830.100(B)(2) exist, installation of the intersystem bonding termination is not required. An accessible means external to enclosures for connecting intersystem bonding and grounding electrode conductors shall be permitted at the service equipment and at the disconnecting means for any additional buildings or structures by at least one of the following means:*

- (1) Exposed nonflexible metallic raceways
- (2) An exposed grounding electrode conductor
- (3) Approved means for the external connection of a copper or other corrosion-resistant bonding or grounding electrode conductor to the grounded raceway or equipment

The intersystem bonding at an existing building or structure can be installed as shown in Exhibit 250.42. An intersystem bonding termination of the type shown in Exhibits 250.40 or 250.41 is not required to be installed under the conditions of this exception, but one can be installed instead of the means specified in the exception.

Informational Note No. 1: A 6 AWG copper conductor with one end bonded to the grounded nonflexible metallic raceway or equipment and with 150 mm (6 in.) or more of the other end made accessible on the outside wall is an example of the approved means covered in 250.94, Exception item (3).

Informational Note No. 2: See 770.100, 800.100, 810.21, 820.100, and 830.100 for intersystem bonding and grounding requirements for conductive optical fiber cables, com-

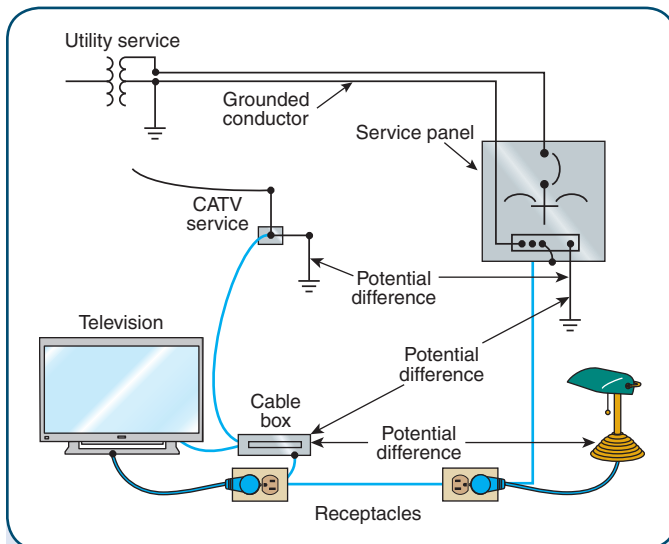

**EXHIBIT 250.42** Methods of providing intersystem bonding at an existing building or structure.

munications circuits, radio and television equipment, CATV circuits and network-powered broadband communications systems, respectively.

Section 250.94 contains a very important requirement to bond together the separate systems that may occur at a premises in order to reduce any differences of potential between them that may occur because of lightning or accidental contact with power lines. Lightning protection systems, communications, radio and TV, and CATV systems are required to be bonded together to minimize the potential differences between the systems that can occur where there is a common interface.

Lack of interconnection can result in a severe shock and fire hazard resulting from differences in potential between multiple systems. The hazard is illustrated in Exhibit 250.43, which shows a CATV cable with its jacket grounded to a separate ground rod and not bonded to the power ground. The cable is connected to the cable decoder and the tuner of a television set. Also connected to the decoder and the television is the 120-volt supply, with one conductor grounded at the service (the power ground). In each case, resistance to ground is present at the grounding electrode. This resistance to ground varies widely, depending on soil conditions and

**EXHIBIT 250.43** A CATV installation that does not comply with the Code, illustrating why bonding between different systems is necessary.

the type of grounding electrode. The resistance at the CATV ground is likely to be higher than the power ground resistance, because the power ground is often an underground metal water piping system or concrete-encased electrode, whereas the CATV ground is commonly a ground rod.

For example, for the CATV installation shown in Exhibit 250.43, assume that a current is induced in the power line by a switching surge or a nearby lightning strike, so that a momentary current of 1000 amperes occurs over the power line to the power line ground. This amount of current is not unusual under such circumstances — the amount could be, and often is, considerably higher. Also assume that the power ground has a resistance of 10 ohms, a very low value in most circumstances (a single ground rod in average soil has a resistance to ground in the neighborhood of 40 ohms).

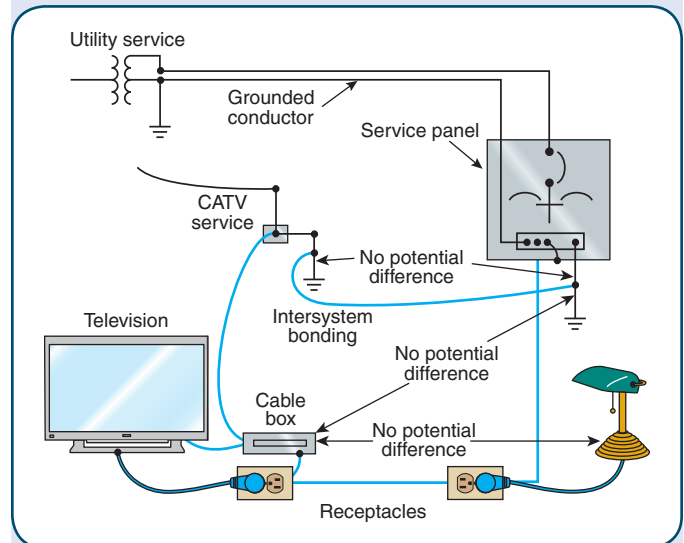

Using Ohm's law, the current through the equipment connected to the electrical system will be raised momentarily to a potential of 10,000 volts (1000 amperes  $\times$  10 ohms). This potential of 10,000 volts would exist between the CATV system and the electrical system and between the grounded conductor within the CATV cable and the grounded surfaces in the walls of the home, such as water pipes (which are connected to the power ground), over which the cable runs. This potential could also appear across a person with one hand on the CATV cable and the other hand on a metal surface connected to the power ground (e.g., a radiator or a refrigerator).

Actual voltage is likely to be many times the 10,000 volts calculated, because extremely low (below normal) values were assumed for both resistance to ground and current. Most insulation systems, however, are not designed to withstand even 10,000 volts. Even if the insulation system does

withstand a 10,000-volt surge, it is likely to be damaged, and breakdown of the insulation system will result in sparking.

The same situation would exist if the current surge were on the CATV cable or a telephone line. The only difference would be the voltage involved, which would depend on the individual resistance to ground of the grounding electrodes.

The solution required by the Code is to bond the two grounding electrode systems together, as shown in Exhibit 250.44, or to connect the CATV cable jacket to the power ground. When one system is raised above ground potential, the second system rises to the same potential, and no voltage exists between the two grounding systems.

**EXHIBIT 250.44** A cable TV installation that complies with 250.94.

The bonding requirement of 250.94 addresses the difficulties sometimes encountered by communications and CATV installers trying to properly bond their respective systems together and to the electrical supply system. These difficulties arise from the increasing use of nonmetallic materials for water pipe, fittings, water meters, and service conduit. In the past, bonding between communications, CATV, and power systems was usually achieved by connecting the communications protector grounds or cable shield to an interior metallic water pipe, because the pipe was often used as the power grounding electrode. Thus, the requirement that the power, communications, CATV cable shield, and metallic water piping systems be bonded together was easily satisfied. If the power was grounded to one of the other electrodes permitted by the Code, usually by a made electrode such as a ground rod, the bond was connected to the power grounding electrode conductor or to a metallic service raceway, since at least one of these was usually accessible.

With the proliferation of plastic water pipe and the service equipment sometimes being installed in finished areas (often flush-mounted), where the grounding electrode conductor is typically concealed, as well as the increased use of nonmetallic service-entrance conduit, communications and CATV installers often do not have access to a suitable point for connecting bonding jumpers or grounding electrode conductors. For further information, see the commentary following 820.100(D), Informational Note No. 2.

### 250.96 Bonding Other Enclosures

**(A) General.** Metal raceways, cable trays, cable armor, cable sheath, enclosures, frames, fittings, and other metal non-current-carrying parts that are to serve as **equipment** grounding conductors, with or without the use of supplementary equipment grounding conductors, shall be bonded where necessary to ensure electrical continuity and the capacity to conduct safely any fault current likely to be imposed on them. Any nonconductive paint, enamel, or similar coating shall be removed at threads, contact points, and contact surfaces or be connected by means of fittings designed so as to make such removal unnecessary.

**(B) Isolated Grounding Circuits.** Where installed for the reduction of electrical noise (electromagnetic interference) on the grounding circuit, an equipment enclosure supplied by a branch circuit shall be permitted to be isolated from a raceway containing circuits supplying only that equipment by one or more listed nonmetallic raceway fittings located at the point of attachment of the raceway to the equipment enclosure. The metal raceway shall comply with provisions of this article and shall be supplemented by an internal insulated equipment grounding conductor installed in accordance with 250.146(D) to ground the equipment enclosure.

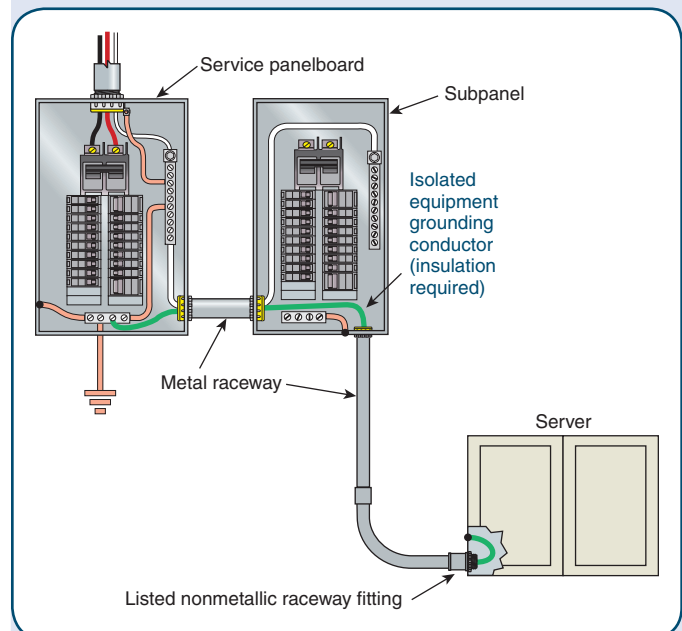

Informational Note: Use of an isolated equipment grounding conductor does not relieve the requirement for grounding the raceway system.

To reduce electromagnetic interference, 250.96(B) permits electronic equipment to be isolated from the raceway in a manner similar to that for cord-and-plug-connected equipment. This section also specifies that a metal equipment enclosure supplied by a branch circuit is the subject of the requirement and that subsequent wiring, raceways, or other equipment beyond the insulating fitting is not permitted.

Exhibits 250.45 and 250.46 illustrate installations with isolated equipment grounding conductors. In Exhibit 250.45, the metal raceway is bonded through its attachment to the grounded service equipment enclosure which addresses the concern mentioned in the Informational Note to 250.96(B). In Exhibit 250.46, the isolated equipment grounding con-

**EXHIBIT 250.45** An installation in which the electronic equipment is grounded through the isolated equipment grounding conductor.

**EXHIBIT 250.46** An installation in which the isolated equipment grounding conductor is allowed to pass through the subpanel without connecting to the grounding bus to terminate at the service grounding bus.

ductor (which is required to be insulated in order to prevent inadvertent contact with grounded enclosures and raceways) passes through the downstream feeder panelboard and terminates in the service equipment, as is permitted in 408.40, Exception. In order to meet the performance objectives for the grounding and bonding of electrical equipment specified in 250.4 and more specifically 250.4(A)(5), the insulated

equipment grounding conductor, regardless of where it terminates in the distribution system, must be connected in a manner that creates an effective path for ground-fault current.

### 250.97 Bonding for Over 250 Volts

For circuits of over 250 volts to ground, the electrical continuity of metal raceways and cables with metal sheaths that contain any conductor other than service conductors shall be ensured by one or more of the methods specified for services in 250.92(B), except for (B)(1).

*Exception: Where oversized, concentric, or eccentric knockouts are not encountered, or where a box or enclosure with concentric or eccentric knockouts is listed to provide a reliable bonding connection, the following methods shall be permitted:*

- (1) Threadless couplings and connectors for cables with metal sheaths
- (2) Two locknuts, on rigid metal conduit or intermediate metal conduit, one inside and one outside of boxes and cabinets
- (3) Fittings with shoulders that seat firmly against the box or cabinet, such as electrical metallic tubing connectors, flexible metal conduit connectors, and cable connectors, with one locknut on the inside of boxes and cabinets
- (4) Listed fittings

Bonding around prepunched concentric or eccentric knockouts is not required if the enclosure containing the knockouts has been tested and is listed as suitable for bonding. Fittings, such as EMT connectors, cable connectors, and similar fittings with shoulders that seat firmly against the metal of a box or cabinet, are permitted to be installed with only one locknut on the inside of the box.

Guide card information from the UL *Guide Information for Electrical Equipment — The White Book* indicates that concentric and eccentric knockouts of all metallic outlet boxes evaluated in accordance with UL 514A, *Metallic Outlet Boxes*, are suitable for bonding in circuits of above or below 250 volts to ground without the use of additional bonding equipment. The guide card information further indicates that metal outlet boxes may be marked to indicate this condition of use. The characteristic of having concentric or eccentric knockouts suitable for bonding above and below 250 volts to ground permits the attachment of metal raceways and metal cables without having to employ any special bonding equipment, such as bonding-type locknuts or bonding bushings. This suitability is identified as a prerequisite in the exception to 250.97, which permits the connection of a

raceway or cable to an enclosure without having to use special bonding hardware under any of the three methods specified in the exception.

### 250.98 Bonding Loosely Jointed Metal Raceways

Expansion fittings and telescoping sections of metal raceways shall be made electrically continuous by equipment bonding jumpers or other means.

### 250.100 Bonding in Hazardous (Classified) Locations

Regardless of the voltage of the electrical system, the electrical continuity of non-current-carrying metal parts of equipment, raceways, and other enclosures in any hazardous (classified) location as defined in 500.5 shall be ensured by any of the bonding methods specified in 250.92(B)(2) through (B)(4). One or more of these bonding methods shall be used whether or not equipment grounding conductors of the wire type are installed.

### 250.102 Bonding Conductors and Jumpers

**(A) Material.** Bonding jumpers shall be of copper or other corrosion-resistant material. A bonding jumper shall be a wire, bus, screw, or similar suitable conductor.

**(B) Attachment.** Bonding jumpers shall be attached in the manner specified by the applicable provisions of 250.8 for circuits and equipment and by 250.70 for grounding electrodes.

#### (C) Size — Supply-Side Bonding Jumper.

**(1) Size for Supply Conductors in a Single Raceway or Cable.** The supply-side bonding jumper shall not be smaller than the sizes shown in Table 250.66 for grounding electrode conductors. Where the ungrounded supply conductors are larger than 1100 kcmil copper or 1750 kcmil aluminum, the supply-side bonding jumper shall have an area not less than 12½ percent of the area of the largest set of ungrounded supply conductors.

**(2) Size for Parallel Conductor Installations.** Where the ungrounded supply conductors are paralleled in two or more raceways or cables, and an individual supply-side bonding jumper is used for bonding these raceways or cables, the size of the supply-side bonding jumper for each raceway or cable shall be selected from Table 250.66 based on the size of the ungrounded supply conductors in each raceway or cable. A single supply-side bonding jumper installed for bonding two or more raceways or cables shall be sized in accordance with 250.102(C)(1).

Similar to the way that the main bonding jumper is sized per 250.28(D), supply-side bonding jumpers are sized based on the size of the ungrounded conductors they are associated with. For small capacity installations, this is a matter of simply determining the size of the largest ungrounded conductor in the supply circuit and selecting the supply-side bonding jumper directly from Table 250.66. For installation(s) where the size of the ungrounded conductors exceeds 1100-kcmil copper or 1750-kcmil aluminum, the size of the supply-side bonding jumper(s) is calculated based on a 12.5 percent sizing relationship between it and the ungrounded conductor. Where an installation consists of multiple raceways for parallel conductors, an individual supply-side bonding jumper can be installed for each raceway, and this jumper is sized based on the size of the ungrounded conductors in that raceway.

#### Application Example

A 3-phase, 1600-ampere service is supplied using five 350-kcmil THWN conductors per phase. The parallel conductors are installed in five separate runs of rigid metal conduit. In accordance with 300.12, Exception No. 2, a supply-side bonding jumper is needed for each raceway at the point it enters the open-bottom switchboard. Using 250.102(C)(2), size the supply-side bonding jumper for each raceway.

**STEP 1.** Determine the size of the largest ungrounded conductor in each raceway – 350 kcmil.

**STEP 2.** Determine the size of the supply-side bonding jumper for each raceway using the “over 3/0 through 350” row in Table 250.66. This results in a 2 AWG copper or 1/0 AWG aluminum supply-side bonding jumper.

#### Solution

If a single supply-side bonding jumper is used to bond all five raceways, the size is determined in accordance with 250.102(C)(1) using the following calculation:

5 parallel 350-kcmil conductors:

$$5 \times 350 = 1750 \text{ kcmil}$$

This total exceeds 1100 kcmil, therefore the total is multiplied by 0.125 (12.5%):

$$1750 \text{ kcmil} \times 0.125 = 218.75 \text{ kcmil}$$

From Chapter 9, Table 8, the next standard conductor size is 250-kcmil copper. If an aluminum supply-side bonding jumper is used, the requirements of 250.102(C)(3) must be applied.

From an installation standpoint, it is likely that installing the five smaller supply-side bonding jumpers (one to each conduit) will facilitate proper bonding of the raceways when compared to installing a single, 250-kcmil conductor through the five fittings that are used to connect the bonding jumper to the rigid metal conduits.

**(3) Different Materials.** Where the ungrounded supply conductors and the supply-side bonding jumper are of different materials (copper or aluminum), the minimum size of the supply-side bonding jumper shall be based on the assumed use of ungrounded conductors of the same material as the supply-side bonding jumper and with an ampacity equivalent to that of the installed ungrounded supply conductors.

**(D) Size — Equipment Bonding Jumper on Load Side of an Overcurrent Device.** The equipment bonding jumper on the load side of an overcurrent device(s) shall be sized in accordance with 250.122.

A single common continuous equipment bonding jumper shall be permitted to connect two or more raceways or cables if the bonding jumper is sized in accordance with 250.122 for the largest overcurrent device supplying circuits therein.

**(E) Installation.** Bonding jumpers or conductors and equipment bonding jumpers shall be permitted to be installed inside or outside of a raceway or an enclosure.

**(1) Inside a Raceway or an Enclosure.** If installed inside a raceway, equipment bonding jumpers and bonding jumpers or conductors shall comply with the requirements of 250.119 and 250.148.

**(2) Outside a Raceway or an Enclosure.** If installed on the outside, the length of the bonding jumper or conductor or equipment bonding jumper shall not exceed 1.8 m (6 ft) and shall be routed with the raceway or enclosure.

*Exception: An equipment bonding jumper or supply-side bonding jumper longer than 1.8 m (6 ft) shall be permitted at outside pole locations for the purpose of bonding or grounding isolated sections of metal raceways or elbows installed in exposed risers of metal conduit or other metal raceway, and for bonding grounding electrodes, and shall not be required to be routed with a raceway or enclosure.*

As is permitted by 250.102(E), equipment bonding jumpers installed on the outside of metal raceways or enclosures is a practical solution to ensuring the effective path for ground-fault current is maintained around sections of raceway, fittings, or other connection points that impede the continuity of the bonding and grounding connections. For example, it would be impractical to install the bonding jumper for a conduit expansion joint on the inside of the conduit. For some metal raceway and rigid conduit systems and conduit systems in hazardous (classified) locations, installing the bonding jumper where it is visible and accessible for inspection and maintenance is desirable. An external bonding jumper

has a higher impedance than an internal bonding jumper, but by limiting the length of the bonding jumper to 6 ft and routing it with the raceway, the increase in the impedance of the equipment grounding circuit is insignificant. Exhibit 250.47 illustrates a bonding jumper run outside a length of flexible metal conduit. Because the function of a bonding jumper is readily apparent, it does not have to be identified using one of the means specified in 250.119 for equipment grounding conductors. Using green marking or insulation on an equipment bonding jumper is also not prohibited by the *Code*.

**EXHIBIT 250.47** A bonding jumper along the outside of a flexible metal conduit.

The exception provides a practical solution to bonding sections of metal raceways installed on exterior poles. The 6-ft length restriction in the main requirement is relaxed in the exception so that a bonding jumper sized in accordance with either 250.102 (C) or (D), as applicable, can be run up the pole to a point where it is practicable to connect it to either the grounded conductor or the equipment grounding conductor, depending on whether the conductors are service conductors or conductors installed on the load-side of the service point.

**(3) Protection.** Bonding jumpers or conductors and equipment bonding jumpers shall be installed in accordance with 250.64(A) and (B).

## 250.104 Bonding of Piping Systems and Exposed Structural Steel

**(A) Metal Water Piping.** The metal water piping system shall be bonded as required in (A)(1), (A)(2), or (A)(3) of

this section. The bonding jumper(s) shall be installed in accordance with 250.64(A), (B), and (E). The points of attachment of the bonding jumper(s) shall be accessible.

**(1) General.** Metal water piping system(s) installed in or attached to a building or structure shall be bonded to the service equipment enclosure, the grounded conductor at the service, the grounding electrode conductor where of sufficient size, or to the one or more grounding electrodes used. The bonding jumper(s) shall be sized in accordance with Table 250.66 except as permitted in 250.104(A)(2) and (A)(3).

Bonding the metal water piping system of a building or structure, as required by 250.104(A) is not the same as using the metal water piping system as a grounding electrode. Bonding to the grounding electrode system places the bonded components at the same voltage level. For example, a current of 2000 amperes across 25 ft of 6 AWG copper conductor produces a voltage differential of approximately 26 volts. Sections 250.104(A)(1) and (A)(3) require the metal water piping system of a building or structure to be bonded to the service equipment or grounding electrode conductor or, where supplied by a feeder or branch circuit, to the building or structure disconnecting means or grounding electrode conductor. Bonding requirements for buildings with multiple occupancies and isolated metal water piping systems are specified in 250.104(A)(2). See the commentary associated with this section.

Where it cannot be reasonably concluded that the hot and cold water pipes are reliably bonded through mechanical connections, an electrical bonding jumper is required to ensure that this connection is made. Some judgment must be exercised for each installation. Isolated sections of metal piping (such as may be used for a plumbing fixture connection) that are connected to an overall nonmetallic water piping system are not subject to the requirements of 250.104(A). The isolated sections are not a metal water piping system. The special installation requirements provided in 250.64(A), (B), and (E) also apply to the water piping bonding jumper.

**(2) Buildings of Multiple Occupancy.** In buildings of multiple occupancy where the metal water piping system(s) installed in or attached to a building or structure for the individual occupancies is metallically isolated from all other occupancies by use of nonmetallic water piping, the metal water piping system(s) for each occupancy shall be permitted to be bonded to the equipment grounding terminal of the panelboard or switchboard enclosure (other than service equipment) supplying that occupancy. The bonding jumper shall be sized in accordance with Table 250.122, based on the rating of the overcurrent protective device for the circuit supplying the occupancy.

Section 250.104(A)(2) recognizes that the increased use of nonmetallic water piping mains can result in the interior metal piping system of a multiple-occupancy building to be isolated from ground and from the other occupancies. Therefore, the water pipe is permitted to be bonded to the panel-board or switchboard that serves only that particular occupancy. The bonding jumper, in this case, is permitted to be sized according to Table 250.122, based on the size of the main overcurrent device supplying the occupancy.

**(3) Multiple Buildings or Structures Supplied by a Feeder(s) or Branch Circuit(s).** The metal water piping system(s) installed in or attached to a building or structure shall be bonded to the building or structure disconnecting means enclosure where located at the building or structure, to the equipment grounding conductor run with the supply conductors, or to the one or more grounding electrodes used. The bonding jumper(s) shall be sized in accordance with 250.66, based on the size of the feeder or branch circuit conductors that supply the building. The bonding jumper shall not be required to be larger than the largest ungrounded feeder or branch circuit conductor supplying the building.

**(B) Other Metal Piping.** If installed in, or attached to, a building or structure, a metal piping system(s), including gas piping, that is likely to become energized shall be bonded to the service equipment enclosure; the grounded conductor at the service; the grounding electrode conductor, if of sufficient size; or to one or more grounding electrodes used. The bonding conductor(s) or jumper(s) shall be sized in accordance with 250.122, using the rating of the circuit that is likely to energize the piping system(s). The equipment grounding conductor for the circuit that is likely to energize the piping shall be permitted to serve as the bonding means. The points of attachment of the bonding jumper(s) shall be accessible.

Informational Note No. 1: Bonding all piping and metal air ducts within the premises will provide additional safety.

Informational Note No. 2: Additional information for gas piping systems can be found in Section 7.13 of NFPA 54-2009, *National Fuel Gas Code*.

Unlike the metal piping systems covered in 250.104(A), the requirements in 250.104(B) apply only to metal piping systems that are “likely to become energized.” Where this phrase is used in the *Code*, it means that the failure of electrical insulation on a conductor can result in normally non-current-carrying metal parts becoming energized. For the purposes of 250.104(B), where metal piping systems and electrical circuits interface through mechanical and electrical connections within equipment, a failure of electrical in-

sulation can result in the connected piping system(s) becoming energized. Gas appliances are a common example of metal gas piping and electrical circuits being connected to a common piece of equipment. The required bonding of piping systems that are likely to be energized can occur at the same locations specified in 250.104(A), or as permitted in 250.104(B), where the equipment grounding conductor of the circuit that is likely to energize is bonded to equipment. Typically, the use of an additional bonding jumper is not necessary to comply with 250.104(B) because the equipment grounding connection to the non-current-carrying metal parts of the appliance also provides a bonding connection to the metal piping attached to the appliance. Section 250.104(B) is a requirement to bond the piping system, and not to make the piping a component of the grounding electrode systems. Therefore, this requirement does not conflict with 250.52(B)(1), which prohibits the use of metal underground gas piping as a grounding electrode for electrical services or other sources of supply. To prevent the underground gas piping from inadvertently becoming a grounding electrode, there must be electrical isolation between the portion that is required to be bonded from the underground segment of metal gas piping. This isolation may be inherent at the interface between the gas supplier’s equipment and the premises gas piping and provides compliance with both 250.52(B)(1) and 250.104(B).

**(C) Structural Metal.** Exposed structural metal that is interconnected to form a metal building frame and is not intentionally grounded or bonded and is likely to become energized shall be bonded to the service equipment enclosure; the grounded conductor at the service; the disconnecting means for buildings or structures supplied by a feeder or branch circuit; the grounding electrode conductor, if of sufficient size; or to one or more grounding electrodes used. The bonding jumper(s) shall be sized in accordance with Table 250.66 and installed in accordance with 250.64(A), (B), and (E). The points of attachment of the bonding jumper(s) shall be accessible unless installed in compliance with 250.68(A), Exception No. 2.

Section 250.104(C) requires exposed metal building framework that is not intentionally or inherently grounded to be bonded to the service equipment or grounding electrode system. This requirement applies to all metal framework, not only to steel framework.

**(D) Separately Derived Systems.** Metal water piping systems and structural metal that is interconnected to form a building frame shall be bonded to separately derived systems in accordance with (D)(1) through (D)(3).

**(1) Metal Water Piping System(s).** The grounded conductor of each separately derived system shall be bonded to the nearest available point of the metal water piping system(s) in the area served by each separately derived system. This connection shall be made at the same point on the separately derived system where the grounding electrode conductor is connected. Each bonding jumper shall be sized in accordance with Table 250.66 based on the largest ungrounded conductor of the separately derived system.

*Exception No. 1: A separate bonding jumper to the metal water piping system shall not be required where the metal water piping system is used as the grounding electrode for the separately derived system and the water piping system is in the area served.*

*Exception No. 2: A separate water piping bonding jumper shall not be required where the metal frame of a building or structure is used as the grounding electrode for a separately derived system and is bonded to the metal water piping in the area served by the separately derived system.*

**(2) Structural Metal.** Where exposed structural metal that is interconnected to form the building frame exists in the area served by the separately derived system, it shall be bonded to the grounded conductor of each separately derived system. This connection shall be made at the same point on the separately derived system where the grounding electrode conductor is connected. Each bonding jumper shall be sized in accordance with Table 250.66 based on the largest ungrounded conductor of the separately derived system.

*Exception No. 1: A separate bonding jumper to the building structural metal shall not be required where the metal frame of a building or structure is used as the grounding electrode for the separately derived system.*

*Exception No. 2: A separate bonding jumper to the building structural metal shall not be required where the water piping of a building or structure is used as the grounding electrode for a separately derived system and is bonded to the building structural metal in the area served by the separately derived system.*

Section 250.104(D) requires that where a separately derived system supplies the power, the metal piping system and the exposed structural metal in the area supplied by the separately derived system must be bonded to the grounded conductor at the point nearest the derived system and that this connection must be accessible. Where either of these two building elements is used as the grounding electrode for the separately derived system, it is not necessary to provide an additional bonding jumper to whichever one is being used as the electrode per Exception No. 1 to 250.104(D)(1) and (2).

Exception No. 2 to 250.104(D)(1) and to (D)(2) permit the following approaches for bonding metal piping or metal structures to separately derived systems. Where the building metal structure is used as the grounding electrode for a separately derived system, it is permitted to install a bonding jumper between the metal structure and the water piping, thus eliminating the need to run a separate bonding jumper from the separately derived system source or distribution equipment to the water piping. The same approach can be taken for the structural metal where metal water piping is serving as the electrode for the separately derived system and a bonding jumper is installed from the piping to the metal framework in the area served by that system. Any bonding jumper used in applying these exceptions is sized from 250.66 based on the largest ungrounded supply conductor of the separately derived system.

**(3) Common Grounding Electrode Conductor.** Where a common grounding electrode conductor is installed for multiple separately derived systems as permitted by 250.30(A)(6), and exposed structural metal that is interconnected to form the building frame or interior metal piping exists in the area served by the separately derived system, the metal piping and the structural metal member shall be bonded to the common grounding electrode conductor in the area served by the separately derived system.

*Exception: A separate bonding jumper from each derived system to metal water piping and to structural metal members shall not be required where the metal water piping and the structural metal members in the area served by the separately derived system are bonded to the common grounding electrode conductor.*

## 250.106 Lightning Protection Systems

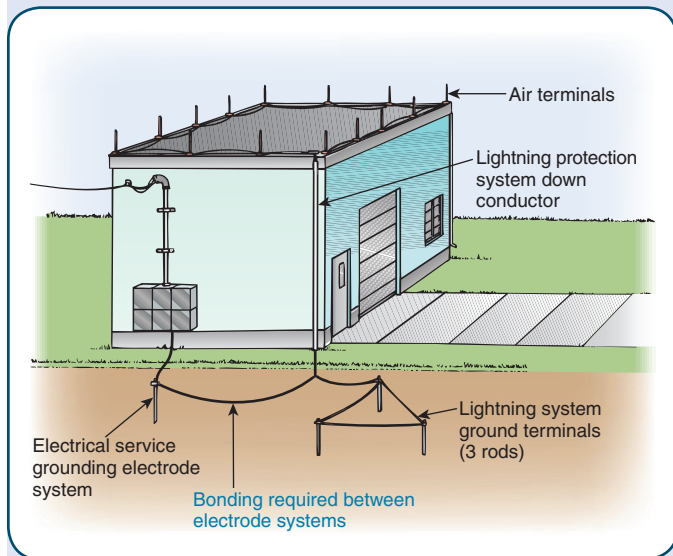

The lightning protection system ground terminals shall be bonded to the building or structure grounding electrode system.

Informational Note No. 1: See 250.60 for use of strike termination devices. For further information, see NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*, which contains detailed information on grounding, bonding, and sideflash distance from lightning protection systems.

Informational Note No. 2: Metal raceways, enclosures, frames, and other non-current-carrying metal parts of electrical equipment installed on a building equipped with a lightning protection system may require bonding or spacing from the lightning protection conductors in accordance with NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*.

Section 250.106 specifies that the grounding electrode system of the lightning protection system be bonded to the elec-

trical service grounding electrode system, as shown in Exhibit 250.48. A similar requirement is found in Section 4.14 of NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*. Additional bonding between the lightning protection system and the electrical system may be necessary based on proximity and whether separation between the systems is through air or building materials.

**EXHIBIT 250.48** Bonding between the lightning system ground terminals and the electrical service grounding electrode system, in accordance with 250.106.

Informational Note No. 2 to 250.106 references NFPA 780-2011 for guidance on determining the need for additional bonding connections. Subsection 4.21.2 of NFPA 780 includes a method for calculating flashover distances.

## VI. Equipment Grounding and Equipment Grounding Conductors

### 250.110 Equipment Fastened in Place (Fixed) or Connected by Permanent Wiring Methods

Exposed, normally non-current-carrying metal parts of fixed equipment supplied by or enclosing conductors or components that are likely to become energized shall be connected to an equipment grounding conductor under any of the following conditions:

Exposed, non-current-carrying metal parts of fixed equipment that are not likely to become energized are not required

to be grounded. These parts include some metal nameplates on nonmetallic enclosures and small parts, such as bolts and screws, if they are located so that they are not likely to become energized.

- (1) Where within 2.5 m (8 ft) vertically or 1.5 m (5 ft) horizontally of ground or grounded metal objects and subject to contact by persons
- (2) Where located in a wet or damp location and not isolated
- (3) Where in electrical contact with metal
- (4) Where in a hazardous (classified) location as covered by Articles 500 through 517
- (5) Where supplied by a wiring method that provides an equipment grounding conductor, except as permitted by 250.86 Exception No. 2 for short sections of metal enclosures
- (6) Where equipment operates with any terminal at over 150 volts to ground

*Exception No. 1: If exempted by special permission, the metal frame of electrically heated appliances that have the frame permanently and effectively insulated from ground shall not be required to be grounded.*

*Exception No. 2: Distribution apparatus, such as transformer and capacitor cases, mounted on wooden poles at a height exceeding 2.5 m (8 ft) above ground or grade level shall not be required to be grounded.*

*Exception No. 3: Listed equipment protected by a system of double insulation, or its equivalent, shall not be required to be connected to the equipment grounding conductor. Where such a system is employed, the equipment shall be distinctively marked.*

### 250.112 Specific Equipment Fastened in Place (Fixed) or Connected by Permanent Wiring Methods

Except as permitted in 250.112(F) and (I), exposed, normally non-current-carrying metal parts of equipment described in 250.112(A) through (K), and normally non-current-carrying metal parts of equipment and enclosures described in 250.112(L) and (M), shall be connected to an equipment grounding conductor, regardless of voltage.

**(A) Switchboard Frames and Structures.** Switchboard frames and structures supporting switching equipment, except frames of 2-wire dc switchboards where effectively insulated from ground.

Section 250.112(A) clarifies that dc switchboards insulated from ground are not required to be grounded.

**(B) Pipe Organs.** Generator and motor frames in an electrically operated pipe organ, unless effectively insulated from ground and the motor driving it.

**(C) Motor Frames.** Motor frames, as provided by 430.242.

**(D) Enclosures for Motor Controllers.** Enclosures for motor controllers unless attached to ungrounded portable equipment.

**(E) Elevators and Cranes.** Electrical equipment for elevators and cranes.

**(F) Garages, Theaters, and Motion Picture Studios.** Electrical equipment in commercial garages, theaters, and motion picture studios, except pendant lampholders supplied by circuits not over 150 volts to ground.

**(G) Electric Signs.** Electric signs, outline lighting, and associated equipment as provided in 600.7.

**(H) Motion Picture Projection Equipment.** Motion picture projection equipment.

**(I) Remote-Control, Signaling, and Fire Alarm Circuits.** Equipment supplied by Class 1 circuits shall be grounded unless operating at less than 50 volts. Equipment supplied by Class 1 power-limited circuits, by Class 2 and Class 3 remote-control and signaling circuits, and by fire alarm circuits shall be grounded where system grounding is required by Part II or Part VIII of this article.

**(J) Luminaires.** Luminaires as provided in Part V of Article 410.

**(K) Skid-Mounted Equipment.** Permanently mounted electrical equipment and skids shall be connected to the equipment grounding conductor sized as required by 250.122.

**(L) Motor-Operated Water Pumps.** Motor-operated water pumps, including the submersible type.

The requirement of 250.112(L) is intended to reduce stray voltages and minimize shock hazard during maintenance, when the pump is removed from the well casing and tested. During normal operation, a ground fault to the casing of a water pump can be a shock hazard if exposed or it could energize a metal well casing if the pump is a submersible type.

**(M) Metal Well Casings.** Where a submersible pump is used in a metal well casing, the well casing shall be connected to the pump circuit equipment grounding conductor.

Section 250.112(M) is intended to prevent a shock hazard that could exist due to a potential difference between the pump, which is grounded to the system ground, and the metal well casing. This grounding and bonding connection also provides a return path for ground-fault current resulting from the pump circuit conductors coming in electrical contact with the metal well casing.

## 250.114 Equipment Connected by Cord and Plug

Under any of the conditions described in 250.114(1) through (4), exposed, normally non-current-carrying metal parts of cord-and-plug-connected equipment shall be connected to the equipment grounding conductor.

*Exception: Listed tools, listed appliances, and listed equipment covered in 250.114(2) through (4) shall not be required to be connected to an equipment grounding conductor where protected by a system of double insulation or its equivalent. Double insulated equipment shall be distinctively marked.*

The exception to 250.114 recognizes listed double-insulated appliances, motor-operated handheld tools, stationary and fixed motor-operated tools, and light industrial motor-operated tools as not requiring equipment grounding connections.

- (1) In hazardous (classified) locations (see Articles 500 through 517)
- (2) Where operated at over 150 volts to ground

*Exception No. 1: Motors, where guarded, shall not be required to be connected to an equipment grounding conductor.*

*Exception No. 2: Metal frames of electrically heated appliances, exempted by special permission, shall not be required to be connected to an equipment grounding conductor, in which case the frames shall be permanently and effectively insulated from ground.*

- (3) In residential occupancies:
  - a. Refrigerators, freezers, and air conditioners
  - b. Clothes-washing, clothes-drying, dish-washing machines; ranges; kitchen waste disposers; information technology equipment; sump pumps and electrical aquarium equipment
  - c. Hand-held motor-operated tools, stationary and fixed motor-operated tools, and light industrial motor-operated tools
  - d. Motor-operated appliances of the following types: hedge clippers, lawn mowers, snow blowers, and wet scrubbers
  - e. Portable handlamps

- (4) In other than residential occupancies:
- Refrigerators, freezers, and air conditioners
  - Clothes-washing, clothes-drying, dish-washing machines; information technology equipment; sump pumps and electrical aquarium equipment
  - Hand-held motor-operated tools, stationary and fixed motor-operated tools, and light industrial motor-operated tools
  - Motor-operated appliances of the following types: hedge clippers, lawn mowers, snow blowers, and wet scrubbers
  - Portable handlamps
  - Cord-and-plug-connected appliances used in damp or wet locations or by persons standing on the ground or on metal floors or working inside of metal tanks or boilers
  - Tools likely to be used in wet or conductive locations

*Exception: Tools and portable handlamps likely to be used in wet or conductive locations shall not be required to be connected to an equipment grounding conductor where supplied through an isolating transformer with an ungrounded secondary of not over 50 volts.*

Tools must be grounded by an equipment grounding conductor within the cord or cable supplying the tool, except where the tool is supplied by an isolating transformer, as permitted by the exception following 250.114(4). Portable tools and appliances protected by an approved system of double insulation must be listed by a qualified electrical testing laboratory as being suitable for the purpose, and the equipment must be distinctively marked as double insulated.

Cord-connected portable tools or appliances are not intended to be used in damp, wet, or conductive locations unless they are grounded, supplied by an isolation transformer with a secondary of not more than 50 volts, or protected by an approved system of double insulation.

Exhibit 250.49 shows an example of lighting equipment supplied through an isolating transformer operating at 6 or 12 volts that provides safe illumination for work inside boilers, tanks, and similar locations that may be metal or wet.

### 250.116 Nonelectrical Equipment

The metal parts of the following nonelectrical equipment described in this section shall be connected to the equipment grounding conductor:

- Frames and tracks of electrically operated cranes and hoists
- Frames of nonelectrically driven elevator cars to which electrical conductors are attached
- Hand-operated metal shifting ropes or cables of electric elevators

**EXHIBIT 250.49** Lighting equipment supplied through an isolating transformer operating at 6 or 12 volts and therefore not required to be grounded. (Courtesy of Woodhead Industries, a division of Molex Incorporated)

**Informational Note:** Where extensive metal in or on buildings may become energized and is subject to personal contact, adequate bonding and grounding will provide additional safety.

Because metal siding on buildings is not electrical equipment, it is outside the scope of the *Code* [see 90.2(A)] and, therefore, is not subject to the *Code* provisions for grounding and bonding. However, luminaires, signs, or receptacles installed on buildings with metal siding could cause the siding to become energized. Grounding of metal siding, while not required, does reduce the risk of shock to persons who may come in contact with siding that has become energized.

### 250.118 Types of Equipment Grounding Conductors

The equipment grounding conductor run with or enclosing the circuit conductors shall be one or more or a combination of the following:

- A copper, aluminum, or copper-clad aluminum conductor. This conductor shall be solid or stranded; insulated, covered, or bare; and in the form of a wire or a busbar of any shape.
- Rigid metal conduit.

As specified in 250.118(2), rigid metal conduit (RMC) is an equipment grounding conductor (EGC), and like other metal

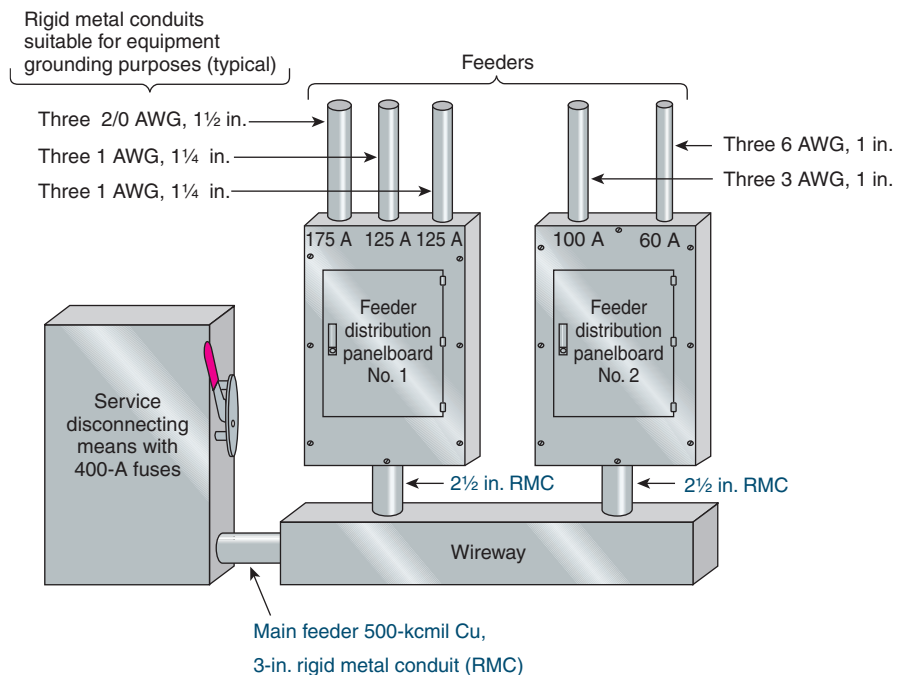

raceways such as intermediate metal conduit (IMC) and electrical metallic tubing (EMT), it can be used as the sole EGC without a wire-type equipment grounding conductor having to be installed in the raceway. As a general rule, the *Code* only requires one EGC and it can be any of the types specified in 250.118(1) through (14). There are specific requirements in the *Code*, such as 517.13(B), where a wire-type equipment grounding conductor is required regardless of the wiring method. However, if a wire-type EGC is installed in a metal raceway and it is not isolated per 250.96(B), the raceway is in parallel with the wire, and the combination of the metal raceway and the wire is the EGC for enclosed circuit(s). Exhibit 250.50 illustrates an installation where RMC is used as the wiring method for feeder conductors on the load side of the service equipment. The wireway can also be used as an equipment grounding conductor without a wire-type EGC per 250.118(13).

- (3) Intermediate metal conduit.
- (4) Electrical metallic tubing.
- (5) Listed flexible metal conduit meeting all the following conditions:
  - a. The conduit is terminated in listed fittings.
  - b. The circuit conductors contained in the conduit are protected by overcurrent devices rated at 20 amperes or less.
  - c. The combined length of flexible metal conduit and flexible metallic tubing and liquidtight flexible metal

conduit in the same ground-fault current path does not exceed 1.8 m (6 ft).

- d. If used to connect equipment where flexibility is necessary to minimize the transmission of vibration from equipment or to provide flexibility for equipment that requires movement after installation, an equipment grounding conductor shall be installed.
- (6) Listed liquidtight flexible metal conduit meeting all the following conditions:
  - a. The conduit is terminated in listed fittings.
  - b. For metric designators 12 through 16 (trade sizes  $\frac{3}{8}$  through  $\frac{1}{2}$ ), the circuit conductors contained in the conduit are protected by overcurrent devices rated at 20 amperes or less.
  - c. For metric designators 21 through 35 (trade sizes  $\frac{3}{4}$  through  $1\frac{1}{4}$ ), the circuit conductors contained in the conduit are protected by overcurrent devices rated not more than 60 amperes and there is no flexible metal conduit, flexible metallic tubing, or liquidtight flexible metal conduit in trade sizes metric designators 12 through 16 (trade sizes  $\frac{3}{8}$  through  $\frac{1}{2}$ ) in the ground-fault current path.
  - d. The combined length of flexible metal conduit and flexible metallic tubing and liquidtight flexible metal conduit in the same ground-fault current path does not exceed 1.8 m (6 ft).
  - e. If used to connect equipment where flexibility is necessary to minimize the transmission of vibration from equipment or to provide flexibility for equipment that

**EXHIBIT 250.50** Various sizes of rigid metal conduit (RMC) used as the sole equipment grounding conductor for the enclosed feeder circuits.

requires movement after installation, an equipment grounding conductor shall be installed.

Where liquidtight flexible metal conduit (LFMC) or flexible metal conduit (FMC) is used to connect to equipment requiring a degree of movement or flexibility as part of its anticipated operating conditions or is used to dampen any vibration between equipment and the nonflexible portion of the wiring system, the requirements in 250.118(6)(e) and 250.118(5)(d) require that the equipment grounding conductor be installed in the LFMC or FMC. Flexible raceways that are used to facilitate connection to equipment but that remain stationary after the connection is made are not covered by the provision of 250.118(5)(d) or 250.118(6)(e).

- (7) Flexible metallic tubing where the tubing is terminated in listed fittings and meeting the following conditions:
  - a. The circuit conductors contained in the tubing are protected by overcurrent devices rated at 20 amperes or less.
  - b. The combined length of flexible metal conduit and flexible metallic tubing and liquidtight flexible metal conduit in the same ground-fault current path does not exceed 1.8 m (6 ft).
- (8) Armor of Type AC cable as provided in 320.108.
- (9) The copper sheath of mineral-insulated, metal-sheathed cable.
- (10) Type MC cable that provides an effective ground-fault current path in accordance with one or more of the following:
  - a. It contains an insulated or uninsulated equipment grounding conductor in compliance with 250.118(1)
  - b. The combined metallic sheath and uninsulated equipment grounding/bonding conductor of interlocked metal tape-type MC cable that is listed and identified as an equipment grounding conductor
  - c. The metallic sheath or the combined metallic sheath and equipment grounding conductors of the smooth or corrugated tube-type MC cable that is listed and identified as an equipment grounding conductor
- (11) Cable trays as permitted in 392.10 and 392.60.
- (12) Cablebus framework as permitted in 370.3.
- (13) Other listed electrically continuous metal raceways and listed auxiliary gutters.
- (14) Surface metal raceways listed for grounding.

Informational Note: For effective ground-fault current path, see 250.2 Definition.

## 250.119 Identification of Equipment Grounding Conductors

Unless required elsewhere in this *Code*, equipment grounding conductors shall be permitted to be bare, covered, or insulated. Individually covered or insulated equipment grounding conductors shall have a continuous outer finish that is either green or green with one or more yellow stripes except as permitted in this section. Conductors with insulation or individual covering that is green, green with one or more yellow stripes, or otherwise identified as permitted by this section shall not be used for ungrounded or grounded circuit conductors.

*Exception: Power-limited Class 2 or Class 3 cables, power-limited fire alarm cables, or communications cables containing only circuits operating at less than 50 volts where connected to equipment not required to be grounded in accordance with 250.112(I) shall be permitted to use a conductor with green insulation or green with one or more yellow stripes for other than equipment grounding purposes.*

The general requirement of 250.119 prohibits re-identifying (such as marking tape to the insulation) any conductor having green- or green-with-yellow-stripe-colored insulation or covering and using it as an ungrounded or grounded conductor. The exception permits limited use of conductors with green-colored insulation for circuit conductors in signaling or other Class 2 or Class 3 circuits operating at less than 50 volts to ground. Many limited energy ac systems are not required to be grounded per 250.20(B); thus, per 250.112(I) there are no grounding requirements for equipment supplied by these circuits.

**(A) Conductors Larger Than 6 AWG.** Equipment grounding conductors larger than 6 AWG shall comply with 250.119(A)(1) and (A)(2).

- (1) An insulated or covered conductor larger than 6 AWG shall be permitted, at the time of installation, to be permanently identified as an equipment grounding conductor at each end and at every point where the conductor is accessible.

*Exception: Conductors larger than 6 AWG shall not be required to be marked in conduit bodies that contain no splices or unused hubs.*

- (2) Identification shall encircle the conductor and shall be accomplished by one of the following:
  - a. Stripping the insulation or covering from the entire exposed length

- b. Coloring the insulation or covering green at the termination
- c. Marking the insulation or covering with green tape or green adhesive labels at the termination

**(B) Multiconductor Cable.** Where the conditions of maintenance and supervision ensure that only qualified persons service the installation, one or more insulated conductors in a multiconductor cable, at the time of installation, shall be permitted to be permanently identified as equipment grounding conductors at each end and at every point where the conductors are accessible by one of the following means:

- (1) Stripping the insulation from the entire exposed length
- (2) Coloring the exposed insulation green
- (3) Marking the exposed insulation with green tape or green adhesive labels

**(C) Flexible Cord.** An uninsulated equipment grounding conductor shall be permitted, but, if individually covered, the covering shall have a continuous outer finish that is either green or green with one or more yellow stripes.

### 250.120 Equipment Grounding Conductor Installation

An equipment grounding conductor shall be installed in accordance with 250.120(A), (B), and (C).

**(A) Raceway, Cable Trays, Cable Armor, Cablebus, or Cable Sheaths.** Where it consists of a raceway, cable tray, cable armor, cablebus framework, or cable sheath or where it is a wire within a raceway or cable, it shall be installed in accordance with the applicable provisions in this *Code* using fittings for joints and terminations approved for use with the type raceway or cable used. All connections, joints, and fittings shall be made tight using suitable tools.

Informational Note: See the UL guide information on FHIT systems for equipment grounding conductors installed in a raceway that are part of an electrical circuit protective system or a fire-rated cable listed to maintain circuit integrity.

**(B) Aluminum and Copper-Clad Aluminum Conductors.** Equipment grounding conductors of bare or insulated aluminum or copper-clad aluminum shall be permitted. Bare conductors shall not come in direct contact with masonry or the earth or where subject to corrosive conditions. Aluminum or copper-clad aluminum conductors shall not be terminated within 450 mm (18 in.) of the earth.

**(C) Equipment Grounding Conductors Smaller Than 6 AWG.** Where not routed with circuit conductors as permitted in 250.130(C) and 250.134(B) Exception No. 2, equipment grounding conductors smaller than 6 AWG shall be protected from physical damage by an identified raceway or

cable armor unless installed within hollow spaces of the framing members of buildings or structures and where not subject to physical damage.

### 250.121 Use of Equipment Grounding Conductors

An equipment grounding conductor shall not be used as a grounding electrode conductor.

This section does not permit one conductor to function as both the equipment grounding conductor and the grounding electrode conductor. Each of these conductors has a specific function in the grounding and bonding system, and trying to apply the requirements for both to a single conductor can result in misapplication of connection, identification, and sizing requirements. In addition, grounding electrode conductors are required to be a wire or busbar-type conductor in accordance with 250.62, whereas equipment grounding conductors are permitted to be a wire-type conductor, a busbar, or a metal raceway.

### 250.122 Size of Equipment Grounding Conductors

**(A) General.** Copper, aluminum, or copper-clad aluminum equipment grounding conductors of the wire type shall not be smaller than shown in Table 250.122, but in no case shall they be required to be larger than the circuit conductors supplying the equipment. Where a cable tray, a raceway, or a cable armor or sheath is used as the equipment grounding conductor, as provided in 250.118 and 250.134(A), it shall comply with 250.4(A)(5) or (B)(4).

Equipment grounding conductors shall be permitted to be sectioned within a multiconductor cable, provided the combined circular mil area complies with Table 250.122.

The last sentence of 250.122(A) provides information similar to that specified in the note to Table 250.122. The prescriptive requirements of 250.118 and 250.122 specify the permitted types and minimum sizes for equipment grounding conductors but the selection and sizing does not necessarily end with these requirements. In 250.122(A) and the note to Table 250.122 the overall grounding and bonding performance requirements of 250.4(A)(5) and (B)(4) are mentioned to remind users of the *Code* that there may be installation conditions such as a long distance between the power source and utilization equipment, that may necessitate additional means or increased EGC sizing to lower the overall impedance of the ground-fault current return path in order to facilitate quick operation of the overcurrent protective device in the event of a line-to-ground fault.

**TABLE 250.122 Minimum Size Equipment Grounding Conductors for Grounding Raceway and Equipment**

Rating or Setting of Automatic Overcurrent Device in Circuit Ahead of Equipment, Conduit, etc., Not Exceeding (Amperes)	Size (AWG or kcmil)	
	Copper	Aluminum or Copper-Clad Aluminum*
15	14	12
20	12	10
60	10	8
100	8	6
200	6	4
300	4	2
400	3	1
500	2	1/0
600	1	2/0
800	1/0	3/0
1000	2/0	4/0
1200	3/0	250
1600	4/0	350
2000	250	400
2500	350	600
3000	400	600
4000	500	750
5000	700	1200
6000	800	1200

Note: Where necessary to comply with 250.4(A)(5) or (B)(4), the equipment grounding conductor shall be sized larger than given in this table.

\*See installation restrictions in 250.120.

**(B) Increased in Size.** Where ungrounded conductors are increased in size, equipment grounding conductors, where installed, shall be increased in size proportionately according to the circular mil area of the ungrounded conductors.

The general requirement for selecting the minimum size equipment grounding conductor is to select directly from Table 250.122 based on the rating or setting of the feeder or branch-circuit overcurrent protective device(s). Where the ungrounded circuit conductors are increased in size to compensate for voltage drop or for any other reason related to proper circuit operation, 250.122(B) requires that the equipment grounding conductors be increased proportionately. Increases in ungrounded circuit conductor size for the purposes of ampacity adjustment, correction, or both are not required to be considered in applying the provisions of 250.122(B). In some cases, use of a conductor with a higher insulation temperature rating allows for compliance with

ampacity adjustment and correction requirements without having to increase the circular mil area of the conductor.

#### Calculation Example

A 240-volt, single-phase, 250-ampere load is supplied from a 300-ampere breaker located in a panelboard 500 ft away. The conductors are 250-kcmil copper, installed in rigid nonmetallic conduit, with a 4 AWG copper equipment grounding conductor. If the conductors are increased to 350 kcmil, what is the minimum size for the equipment grounding conductor based on the proportional-increase requirement?

#### Solution

STEP 1. Calculate the size ratio of the new conductors to the existing conductors:

$$\text{Size ratio} = \frac{350,000 \text{ circular mils}}{250,000 \text{ circular mils}} = 1.4$$

STEP 2. Calculate the cross-sectional area of the new equipment grounding conductor:

$$41,740 \text{ cm} \times 1.4 = 58,436 \text{ cm}$$

According to Chapter 9, Table 8, 4 AWG, the size of the existing grounding conductor, has a cross-sectional area of 41,740 circular mils.

STEP 3. Determine the size of the new equipment grounding conductor. Again, referring to Chapter 9, Table 8, we find that 58,436 circular mils is larger than 3 AWG. The next larger size is 66,360 circular mils, which converts to a 2 AWG copper equipment grounding conductor.

**(C) Multiple Circuits.** Where a single equipment grounding conductor is run with multiple circuits in the same raceway, cable, or cable tray, it shall be sized for the largest overcurrent device protecting conductors in the raceway, cable, or cable tray. Equipment grounding conductors installed in cable trays shall meet the minimum requirements of 392.10(B)(1)(c).

According to 250.122(C), a single equipment grounding conductor must be sized for the largest overcurrent device. It is not required to be sized for the composite of all the circuits in the raceway because it is not anticipated that all circuits will develop faults at the same time. For example, three 3-phase circuits in the same raceway, protected by overcurrent devices rated 30, 60, and 100 amperes, would require only one equipment grounding conductor, sized according to the largest overcurrent device (in this case, 100 amperes). Therefore, an 8 AWG copper or 6 AWG aluminum conductor or copper-clad aluminum conductor is required, according to Table 250.122.

**(D) Motor Circuits.** Equipment grounding conductors for motor circuits shall be sized in accordance with (D)(1) or (D)(2).

**(1) General.** The equipment grounding conductor size shall not be smaller than determined by 250.122(A) based on the rating of the branch-circuit short-circuit and ground-fault protective device.

**(2) Instantaneous-Trip Circuit Breaker and Motor Short-Circuit Protector.** Where the overcurrent device is an instantaneous-trip circuit breaker or a motor short-circuit protector, the equipment grounding conductor shall be sized not smaller than that given by 250.122(A) using the maximum permitted rating of a dual element time-delay fuse selected for branch-circuit short-circuit and ground-fault protection in accordance with 430.52(C)(1), Exception No. 1.

**(E) Flexible Cord and Fixture Wire.** The equipment grounding conductor in a flexible cord with the largest circuit conductor 10 AWG or smaller, and the equipment grounding conductor used with fixture wires of any size in accordance with 240.5, shall not be smaller than 18 AWG copper and shall not be smaller than the circuit conductors. The equipment grounding conductor in a flexible cord with a circuit conductor larger than 10 AWG shall be sized in accordance with Table 250.122.

**(F) Conductors in Parallel.** Where conductors are installed in parallel in multiple raceways or cables as permitted in 310.10(H), the equipment grounding conductors, where used, shall be installed in parallel in each raceway or cable. Where conductors are installed in parallel in the same raceway, cable, or cable tray as permitted in 310.10(H), a single equipment grounding conductor shall be permitted. Equipment grounding conductors installed in cable tray shall meet the minimum requirements of 392.10(B)(1)(c).

Each equipment grounding conductor shall be sized in compliance with 250.122.

Where wire-type equipment grounding conductors are installed in multiple raceways or cables used in parallel conductor arrangements, 250.122(F) requires a full-sized equipment grounding conductor selected from Table 250.122 based on the rating or setting of the overcurrent device protecting the paralleled circuit conductors.

The full-sized equipment grounding conductor is required to prevent overloading and possible burnout of the conductor should a ground fault occur along one of the parallel branches. The installation conditions for paralleled conductors prescribed in 310.10(H) result in proportional distribution of the current-time duty among the several par-

alleled grounding conductors only for overcurrent conditions downstream of the paralleled set of circuit conductors.

Exhibit 250.51 shows a parallel arrangement with two nonmetallic conduits installed underground. For clarity, a one-line diagram with equipment grounding conductors is shown. A ground fault at the enclosure will cause the equipment grounding conductor in the top conduit to carry more than its proportionate share of fault current. The fault is fed by two different conductors of the same phase, one from the left and one from the right. The shortest and lowest-impedance path to ground from the fault to the supply panel-board is through the equipment grounding conductor in the top conduit. The grounding path from the fault through the bottom conduit is longer and of higher impedance. Therefore, the equipment grounding conductor in each raceway must be capable of carrying a major portion of the fault current without burning open.

**EXHIBIT 250.51** Grounding paths for ground fault at the load supplied by parallel conductors in two nonmetallic raceways, illustrating the reason for the requirement of 250.122(F).

Where an installation is made using raceways, compliance with 250.122(F) is accomplished by simply installing a properly sized (based on Table 250.122) equipment grounding conductor selected from in the raceway. Cables, on the other hand are manufactured with the conductors already installed including the equipment grounding conductor. Therefore it is necessary to ascertain that the equipment grounding conductor installed in the cable meets the minimum size per Table 250.122 based on the rating or setting of the overcurrent protective device protecting the ungrounded conductors in the cable. Where cables are used in parallel, the equipment grounding conductor in each cable is required to be sized in accordance with 250.122 based on the rating or setting of the overcurrent protective device that is protecting the conductors connected in parallel. In large capacity circuits this may result in the equipment grounding conductor having to be larger than the ungrounded conductor in an individual cable that is used as part of a larger parallel set.

Equipment grounding conductors are permitted to be connected in parallel per 310.10(H), but each parallel equipment grounding conductor is required to be fully sized per 250.122. The cross-sectional area of sectioned equipment grounding conductors in an individual cable are permitted to be added together to meet the requirement of a fully sized equipment grounding conductor in each cable.

Where parallel conductors are installed in a single raceway or cable tray, it is permitted to install a single equipment grounding conductor in the raceway or cable tray that is sized based on the rating of the overcurrent protective device protecting the parallel circuit conductors.

**(G) Feeder Taps.** Equipment grounding conductors run with feeder taps shall not be smaller than shown in Table 250.122 based on the rating of the overcurrent device ahead of the feeder but shall not be required to be larger than the tap conductors.

Section 250.122(G) clarifies how to size a wire-type equipment grounding conductor for feeder tap installations covered in 240.21(B). This requirement specifies that it is the rating of the overcurrent protective device on the line or supply side of the supply feeder and the tap conductors that is the basis for selection from Table 250.122, rather than the rating of the overcurrent or other device at the load or termination end of the tap conductors. In reviewing how a tapped feeder circuit is arranged, the sizing requirement stands to reason because it is the overcurrent protective device on the supply side of the tap conductors that will respond to a ground-fault condition between the point at which the tap conductors are supplied and the point at which they terminate. In accordance with this paragraph and 250.122(A), the equipment grounding conductor is not required to be larger than the ungrounded conductors. This provision applies only where a wire-type equipment grounding conductor is run with the feeder tap conductors. Other equipment grounding conductors permitted in 250.118 can be used where they meet the requirements for tap conductor wiring methods specified in 240.21(B)(1) through (B)(5).

#### Application Example

A 600-kcmil copper conductor is tapped to a 1200-ampere feeder and supplies a fusible switch with 400-ampere fuses. Where the 400-ampere overcurrent protection is installed at the point the 600-kcmil conductors receive their supply, the equipment grounding conductor from Table 250.122 is a 3 AWG copper or 1 AWG aluminum conductor. However, in this tap conductor application, it is the 1200-ampere device that is on the line side of the 600-kcmil tap conductors, and the equipment grounding conductor from Table 250.122 is based on the 1200-ampere device. In this case, the equip-

ment grounding conductor is required to be a 3/0 AWG copper or 250-kcmil aluminum conductor. This provision applies only where a wire-type equipment grounding conductor is run with the feeder tap conductors.

### 250.124 Equipment Grounding Conductor Continuity

**(A) Separable Connections.** Separable connections such as those provided in drawout equipment or attachment plugs and mating connectors and receptacles shall provide for first-make, last-break of the equipment grounding conductor. First-make, last-break shall not be required where interlocked equipment, plugs, receptacles, and connectors preclude energization without grounding continuity.

**(B) Switches.** No automatic cutout or switch shall be placed in the equipment grounding conductor of a premises wiring system unless the opening of the cutout or switch disconnects all sources of energy.

### 250.126 Identification of Wiring Device Terminals

The terminal for the connection of the equipment grounding conductor shall be identified by one of the following:

- (1) A green, not readily removable terminal screw with a hexagonal head.
- (2) A green, hexagonal, not readily removable terminal nut.
- (3) A green pressure wire connector. If the terminal for the grounding conductor is not visible, the conductor entrance hole shall be marked with the word *green* or *ground*, the letters *G* or *GR*, a grounding symbol, or otherwise identified by a distinctive green color. If the terminal for the equipment grounding conductor is readily removable, the area adjacent to the terminal shall be similarly marked.

Informational Note: See Informational Note Figure 250.126.

**INFORMATIONAL NOTE FIGURE 250.126** One Example of a Symbol Used to Identify the Grounding Termination Point for an Equipment Grounding Conductor.

## VII. Methods of Equipment Grounding

### 250.130 Equipment Grounding Conductor Connections

Equipment grounding conductor connections at the source of separately derived systems shall be made in accordance with 250.30(A)(1). Equipment grounding conductor connec-

tions at service equipment shall be made as indicated in 250.130(A) or (B). For replacement of non-grounding-type receptacles with grounding-type receptacles and for branch-circuit extensions only in existing installations that do not have an equipment grounding conductor in the branch circuit, connections shall be permitted as indicated in 250.130(C).

**(A) For Grounded Systems.** The connection shall be made by bonding the equipment grounding conductor to the grounded service conductor and the grounding electrode conductor.

The grounding and bonding arrangement required by 250.130(A) for a grounded system is illustrated in Exhibit 250.52.

**EXHIBIT 250.52** Grounding and bonding arrangement for grounded systems, per 250.130(A), illustrating connection of the equipment grounding conductor (bus) to the enclosures and the grounded service conductor.

**(B) For Ungrounded Systems.** The connection shall be made by bonding the equipment grounding conductor to the grounding electrode conductor.

**(C) Nongrounding Receptacle Replacement or Branch Circuit Extensions.** The equipment grounding conductor of a grounding-type receptacle or a branch-circuit extension shall be permitted to be connected to any of the following:

- (1) Any accessible point on the grounding electrode system as described in 250.50
- (2) Any accessible point on the grounding electrode conductor
- (3) The equipment grounding terminal bar within the enclosure where the branch circuit for the receptacle or branch circuit originates
- (4) For grounded systems, the grounded service conductor within the service equipment enclosure
- (5) For ungrounded systems, the grounding terminal bar within the service equipment enclosure

Informational Note: See 406.4(D) for the use of a ground-fault circuit-interrupting type of receptacle.

Section 250.130(C) applies to both ungrounded and grounded systems but its most common application is for receptacle replacement of branch circuit extensions in single phase, 120 volt, 15- and 20-ampere, branch circuits, which are required to be supplied by a grounded system per 250.20(B). This section permits a nongrounding-type receptacle to be replaced with a grounding-type receptacle under the following conditions.

1. The branch circuit does not contain an equipment ground.
2. An existing branch circuit is being extended for additional receptacle outlets.
3. An equipment grounding conductor is connected from the receptacle grounding terminal to any accessible point on the grounding electrode system, to any accessible point on the grounding electrode conductor, to the grounded service conductor within the service equipment enclosure, or to the equipment grounding terminal bar in the enclosure from which the circuit is supplied.

The requirement in 250.68(C)(1) does not permit this separate equipment grounding conductor to be connected to the metal water piping of a building or structure beyond the first 5 ft of where the piping enters the building or structure unless the conditions of the exception to 250.68(C)(1) can be met.

Exhibit 250.53 shows a branch-circuit extension made from an existing installation. This method is also permitted to ground a replacement 3-wire receptacle in the existing ungrounded box on the left, where no grounding conductor is available.

**EXHIBIT 250.53** Branch-circuit extension to an existing installation, per 250.130(C), illustrating a separate equipment grounding conductor connected to the grounding electrode system.

### 250.132 Short Sections of Raceway

Isolated sections of metal raceway or cable armor, where required to be grounded, shall be connected to an equipment grounding conductor in accordance with 250.134.

### 250.134 Equipment Fastened in Place or Connected by Permanent Wiring Methods (Fixed) — Grounding

Unless grounded by connection to the grounded circuit conductor as permitted by 250.32, 250.140, and 250.142, non-current-carrying metal parts of equipment, raceways, and other enclosures, if grounded, shall be connected to an equipment grounding conductor by one of the methods specified in 250.134(A) or (B).

Section 250.134 eliminates any conflict between 250.134(A), which requires an equipment grounding conductor to be used for equipment grounding, and 250.32(B)(1), Exception, 250.140, and 250.142, which permit the grounded circuit conductor to be used for equipment grounding if certain specified conditions are met.

**(A) Equipment Grounding Conductor Types.** By connecting to any of the equipment grounding conductors permitted by 250.118.

**(B) With Circuit Conductors.** By connecting to an equipment grounding conductor contained within the same raceway, cable, or otherwise run with the circuit conductors.

To keep the impedance on the equipment grounding conductor at a minimum, 250.134(B) requires the equipment grounding conductor to be run in the same raceway or cable as the circuit conductor(s). This practice allows the magnetic field developed by the circuit conductor and the equipment grounding conductor to cancel, reducing their impedance.

Magnetic flux strength is inversely proportional to the square of the distance between the two conductors. By placing an equipment grounding conductor away from the conductor delivering the fault current, the magnetic flux cancellation decreases. This increases the impedance of the fault path and delays operation of the protective device contrary to the performance requirements specified in 250.4(A)(5) and (B)(4) for the ground-fault current return path.

*Exception No. 1: As provided in 250.130(C), the equipment grounding conductor shall be permitted to be run separately from the circuit conductors.*

Exception No. 1 to 250.134(B) permits an equipment grounding conductor to be run to the grounding electrode separately from the other conductors of an ac circuit. This practice applies only where a grounding-type receptacle is used on a circuit that does not include an equipment grounding conductor. See the commentary following 250.130(C) for further explanation.

*Exception No. 2: For dc circuits, the equipment grounding conductor shall be permitted to be run separately from the circuit conductors.*

Informational Note No. 1: See 250.102 and 250.168 for equipment bonding jumper requirements.

Informational Note No. 2: See 400.7 for use of cords for fixed equipment.

### 250.136 Equipment Considered Grounded

Under the conditions specified in 250.136(A) and (B), the normally non-current-carrying metal parts of the equipment shall be considered grounded.

**(A) Equipment Secured to Grounded Metal Supports.** Electrical equipment secured to and in electrical contact with a metal rack or structure provided for its support and connected to an equipment grounding conductor by one of the means indicated in 250.134. The structural metal frame of a building shall not be used as the required equipment grounding conductor for ac equipment.

In lieu of installing one of the equipment grounding conductor types specified in 250.118 to each piece of equipment supported by a common metal rack, 250.136(A) permits the equipment to be grounded via its mechanical attachment to a rack that is grounded through one or more connections to an equipment grounding conductor or equipment bonding conductor (size of conductor is based on largest overcurrent protective device protecting equipment mounted on the rack). Equipment bolted or securely clamped to the rack will typically provide the necessary electrical contact to ensure that there is a low impedance connection between the rack and the equipment. If the rack has been painted, the provisions of 250.12 have to be followed to ensure that the connection is not impeded by the paint or other nonconductive coating.

Exhibit 250.54 illustrates an example of electrical equipment secured to and in electrical contact with a metal rack that is effectively grounded by the equipment bonding jumper installed between the safety switch and the rack. The permission to use this method for grounding equipment does not extend to equipment support by the structural metal of a

**EXHIBIT 250.54** Mounting equipment to a grounded support structure or rack, an acceptable means of providing the required equipment grounding connection.

building. The physical separation between the circuit conductors and the building steel raises the impedance of the equipment grounding and bonding path and is contrary to the requirements of 250.134(B) and 300.3(B).

**(B) Metal Car Frames.** Metal car frames supported by metal hoisting cables attached to or running over metal sheaves or drums of elevator machines that are connected to an equipment grounding conductor by one of the methods indicated in 250.134.

### 250.138 Cord-and-Plug-Connected Equipment

Non-current-carrying metal parts of cord-and-plug-connected equipment, if grounded, shall be connected to an equipment grounding conductor by one of the methods in 250.138(A) or (B).

#### (A) By Means of an Equipment Grounding Conductor.

By means of an equipment grounding conductor run with the power supply conductors in a cable assembly or flexible cord properly terminated in a grounding-type attachment plug with one fixed grounding contact.

*Exception: The grounding contacting pole of grounding-type plug-in ground-fault circuit interrupters shall be permitted to be of the movable, self-restoring type on circuits operating at not over 150 volts between any two conductors or over 150 volts between any conductor and ground.*

**(B) By Means of a Separate Flexible Wire or Strap.** By means of a separate flexible wire or strap, insulated or bare, connected to an equipment grounding conductor, and protected as well as practicable against physical damage, where part of equipment.

### 250.140 Frames of Ranges and Clothes Dryers

Frames of electric ranges, wall-mounted ovens, counter-mounted cooking units, clothes dryers, and outlet or junction boxes that are part of the circuit for these appliances shall be connected to the equipment grounding conductor in the manner specified by 250.134 or 250.138.

*Exception: For existing branch-circuit installations only where an equipment grounding conductor is not present in the outlet or junction box, the frames of electric ranges, wall-mounted ovens, counter-mounted cooking units, clothes dryers, and outlet or junction boxes that are part of the circuit for these appliances shall be permitted to be connected to the grounded circuit conductor if all the following conditions are met.*

- (1) The supply circuit is 120/240-volt, single-phase, 3-wire; or 208Y/120-volt derived from a 3-phase, 4-wire, wye-connected system.
- (2) The grounded conductor is not smaller than 10 AWG copper or 8 AWG aluminum.
- (3) The grounded conductor is insulated, or the grounded conductor is uninsulated and part of a Type SE service-entrance cable and the branch circuit originates at the service equipment.
- (4) Grounding contacts of receptacles furnished as part of the equipment are bonded to the equipment.

The exception to 250.140 applies only to existing branch circuits supplying the appliances specified in 250.140. The grounded conductor (neutral) of newly installed branch circuits supplying ranges and clothes dryers is not permitted to be used for grounding the non-current-carrying metal parts of the appliances. Branch circuits installed for new appliance installations are required to provide an equipment grounding conductor sized in accordance with 250.122 for grounding the non-current-carrying metal parts.

Prior to the 1996 *Code*, use of the grounded circuit conductor as a grounding conductor was permitted for all installations. In many instances, the wiring method was service-entrance cable with an uninsulated neutral conductor covered by the cable jacket. Where Type SE cable was used to supply ranges and dryers, the branch circuit was required to originate at the service equipment to avoid neutral current from downstream panelboards being imposed on metal objects, such as pipes or ducts.

Caution should be exercised to ensure that new appliances connected to an existing branch circuit are properly grounded. An older appliance connected to a new branch circuit must have its 3-wire cord and plug replaced with a 4-conductor cord, with one of those conductors being an equipment grounding conductor. The bonding jumper be-

tween the neutral and the frame of the appliance must be removed. Where a new range or clothes dryer is connected to an existing branch circuit without an equipment grounding conductor, in which the neutral conductor is used for grounding the appliance frame, it must be ensured that a bonding jumper is in place between the neutral terminal of the appliance and the frame of the appliance.

The grounded circuit conductor of an existing branch circuit is permitted to be used to ground the frame of an electric range, wall-mounted oven, or counter-mounted cooking unit, provided all four conditions of 250.140, Exception, are met. The exception can be applied only where the existing branch-circuit wiring method does not provide an equipment grounding conductor. There are many existing branch circuits in which nonmetallic sheath cable with three insulated circuit conductors and a bare equipment grounding conductor was used to supply a range or clothes dryer. The bare equipment grounding conductor was simply not used because it was permitted to ground the equipment with the insulated neutral conductor of the NM cable. This “extra” conductor results because the bare conductor in a Type NM cable is to be used only as an equipment grounding conductor and cannot be used as a grounded (neutral) conductor in the same manner as is permitted for the uninsulated conductor in Type SE cable.

In addition to grounding the frame of the range or clothes dryer, the grounded circuit conductor of these existing branch circuits is also permitted to be used to ground any junction boxes in the circuit supplying the appliance, and a 3-wire pigtail and range receptacle are permitted to be used.

Exhibit 250.55 shows two examples of existing installations in which Type SE service-entrance cable is used to supply ranges, dryers, wall-mounted ovens, and counter-mounted cooking units. Junction boxes in the supply circuit are also permitted to be grounded from the grounded neutral conductor. In the bottom diagram the service-entrance cable installed from the feeder panelboard to the range or clothes dryer outlet contains an insulated grounded conductor to prevent incidental contact between the conductor and metal enclosures. Such contact could result in current being introduced onto circuit paths other than on the intended path, which is the grounded (neutral) conductor.

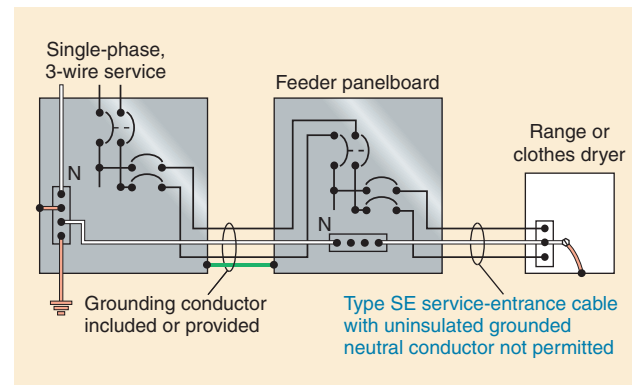

### 250.142 Use of Grounded Circuit Conductor for Grounding Equipment

**(A) Supply-Side Equipment.** A grounded circuit conductor shall be permitted to ground non-current-carrying metal parts of equipment, raceways, and other enclosures at any of the following locations:

- (1) On the supply side or within the enclosure of the ac service-disconnecting means

From Service Equipment

From Feeder Panelboard

**EXHIBIT 250.55** Two existing installations in which the grounded conductor in Type SE service-entrance cable is used for grounding the frames of ranges and clothes dryers, plus associated metal junction boxes, in accordance with 250.140.

- (2) On the supply side or within the enclosure of the main disconnecting means for separate buildings as provided in 250.32(B)
- (3) On the supply side or within the enclosure of the main disconnecting means or overcurrent devices of a separately derived system where permitted by 250.30(A)(1)

On the supply side of a separately derived system disconnecting means, the grounded circuit conductor is permitted by 250.142(A) to ground non-current-carrying metal parts of equipment, raceways, and other enclosures, which is similar to the grounding and bonding of the same types of equipment on the line side of a service-supplied system.

**(B) Load-Side Equipment.** Except as permitted in 250.30(A)(1) and 250.32(B) **Exception**, a grounded circuit conductor shall not be used for grounding non-current-carrying metal parts of equipment on the load side of the

service disconnecting means or on the load side of a separately derived system disconnecting means or the overcurrent devices for a separately derived system not having a main disconnecting means.

*Exception No. 1: The frames of ranges, wall-mounted ovens, counter-mounted cooking units, and clothes dryers under the conditions permitted for existing installations by 250.140 shall be permitted to be connected to the grounded circuit conductor.*

*Exception No. 2: It shall be permissible to ground meter enclosures by connection to the grounded circuit conductor on the load side of the service disconnect where all of the following conditions apply:*

- (1) No service ground-fault protection is installed.
- (2) All meter enclosures are located immediately adjacent to the service disconnecting means.
- (3) The size of the grounded circuit conductor is not smaller than the size specified in Table 250.122 for equipment grounding conductors.

*Exception No. 3: Direct-current systems shall be permitted to be grounded on the load side of the disconnecting means or overcurrent device in accordance with 250.164.*

*Exception No. 4: Electrode-type boilers operating at over 600 volts shall be grounded as required in 490.72(E)(1) and 490.74.*

An important reason why the grounded circuit conductor is not permitted to be grounded on the load side of the service [except as permitted in 250.30, 250.32(B)(1), Exception, and the four exceptions to 250.142(B)] is that, should the grounded service conductor become disconnected at any point on the line side of the ground, the equipment grounding conductor and all conductive parts connected to it would carry the neutral current. Under this condition, the potential to ground of exposed metal parts not normally intended to carry current is raised. This rise in potential on non-current-carrying conductive parts could result in arcing in concealed spaces and could pose a severe shock hazard, particularly if the path is inadvertently opened by a person servicing or repairing piping or ductwork.

Even without an open grounded conductor (usually referred to as an open neutral), a connection between the grounded conductor and the equipment grounding conductor on the load side of the service places the equipment grounding conductor in a parallel circuit path with the grounded conductor. There would be some potential drop on exposed and concealed dead metal parts. The magnitude of this potential difference would be determined by the relative impedances of the equipment grounding path and the grounded

conductor circuits. Not only would the equipment grounding conductor path be affected, but all parallel paths not intended as equipment grounding conductors would be affected as well. The parallel current paths could be metal building structures, metal piping, and metal ducts. The requirements of 250.30 and 250.32(B) have been revised in recent editions of the *Code* to prohibit the creation of parallel paths for normal neutral current.

## 250.144 Multiple Circuit Connections

Where equipment is grounded and is supplied by separate connection to more than one circuit or grounded premises wiring system, an equipment grounding conductor termination shall be provided for each such connection as specified in 250.134 and 250.138.

## 250.146 Connecting Receptacle Grounding Terminal to Box

An equipment bonding jumper shall be used to connect the grounding terminal of a grounding-type receptacle to a grounded box unless grounded as in 250.146(A) through (D). The equipment bonding jumper shall be sized in accordance with Table 250.122 based on the rating of the overcurrent device protecting the circuit conductors.

**(A) Surface-Mounted Box.** Where the box is mounted on the surface, direct metal-to-metal contact between the device yoke and the box or a contact yoke or device that complies with 250.146(B) shall be permitted to ground the receptacle to the box. At least one of the insulating washers shall be removed from receptacles that do not have a contact yoke or device that complies with 250.146(B) to ensure direct metal-to-metal contact. This provision shall not apply to cover-mounted receptacles unless the box and cover combination are listed as providing satisfactory ground continuity between the box and the receptacle. A listed exposed work cover shall be permitted to be the grounding and bonding means when (1) the device is attached to the cover with at least two fasteners that are permanent (such as a rivet) or have a thread locking or screw or nut locking means and (2) when the cover mounting holes are located on a flat non-raised portion of the cover.

The main rule of 250.146 requires an equipment bonding jumper to be installed between the device box and the receptacle grounding terminal. However, 250.146(A) permits the equipment bonding jumper to be omitted where the metal yoke of the device is in direct metal-to-metal contact with the metal device box and at least one of the fiber retention washers for the receptacle mounting screws is removed, as illustrated in Exhibit 250.56.

Bonding jumper not required where direct metal-to-metal contact and at least one screw-retention washer removed

**EXHIBIT 250.56** An example of a box-mounted receptacle attached to a surface box where a bonding jumper from the grounded metal box to the receptacle is not required provided at least one of the insulating washers is removed in accordance with 250.146(A).

Cover-mounted wiring devices, such as on 4-in. square covers, are not considered grounded. Section 250.146(A) does not apply to cover-mounted receptacles, such as the one illustrated in Exhibit 250.57. Box-cover and device combinations listed as providing grounding continuity are permitted. The mounting holes for the cover must be located on a flat, non-raised portion of the cover to provide the best possible surface-to-surface contact and the receptacle must be secured to the cover using not less than two rivets or locking means for threaded attachment means.

**EXHIBIT 250.57** An example of a cover-mounted receptacle attached to a surface box where a bonding jumper from the grounded metal box to the receptacle is not required in accordance with 250.146(A).

**(B) Contact Devices or Yokes.** Contact devices or yokes designed and listed as self-grounding shall be permitted in conjunction with the supporting screws to establish the grounding circuit between the device yoke and flush-type boxes.

An example of the contact devices permitted in 250.146(B) is illustrated in Exhibit 250.58, which shows a receptacle designed with a spring-type grounding strap for holding the mounting screw and establishing the grounding circuit so that an equipment bonding jumper is not required. Such devices are listed as “self-grounding” and are permitted to be used for bonding the flush-mounted receptacle to a grounded metal box.

**EXHIBIT 250.58** A receptacle designed with a listed spring-type grounding strap. The clip holding the bottom mounting screw captive establishes a grounding circuit and eliminates the need to provide a wire-type equipment bonding jumper from the grounded metal box to the receptacle, in accordance with 250.146(B).

**(C) Floor Boxes.** Floor boxes designed for and listed as providing satisfactory ground continuity between the box and the device shall be permitted.

**(D) Isolated Receptacles.** Where installed for the reduction of electrical noise (electromagnetic interference) on the grounding circuit, a receptacle in which the grounding terminal is purposely insulated from the receptacle mounting

means shall be permitted. The receptacle grounding terminal shall be connected to an insulated equipment grounding conductor run with the circuit conductors. This equipment grounding conductor shall be permitted to pass through one or more panelboards without a connection to the panelboard grounding terminal bar as permitted in 408.40, Exception, so as to terminate within the same building or structure directly at an equipment grounding conductor terminal of the applicable derived system or service. Where installed in accordance with the provisions of this section, this equipment grounding conductor shall also be permitted to pass through boxes, wireways, or other enclosures without being connected to such enclosures.

**Informational Note:** Use of an isolated equipment grounding conductor does not relieve the requirement for grounding the raceway system and outlet box.

Section 250.146(D) allows an isolated-ground-type receptacle to be installed without a bonding jumper between the metal device box and the receptacle grounding terminal. However, the performance requirement specified by 250.4(A)(5) has to be complied with, and the isolated equipment grounding conductor must create an effective path for ground-fault current between the receptacle grounding terminal and the source of the branch circuit supplying the receptacle. An insulated equipment grounding conductor, as shown in Exhibit 250.59, is installed with the branch-circuit conductors. This conductor may originate in the service panel, pass through any number of subpanels without being connected to the equipment grounding bus, and terminate at the isolated-ground-type receptacle ground terminal. How-

**EXHIBIT 250.59** An isolated-ground-type receptacle with an insulated equipment grounding conductor and with the device box grounded through the metal raceway.

ever, this isolated equipment grounding conductor arrangement does not exempt the metal device box from being grounded. The metal device box must be grounded either by an equipment grounding conductor run with the circuit conductors or by a wiring method that serves as an equipment grounding conductor. See 250.118 for types of equipment grounding conductors.

According to 250.146(D), where isolated-ground-type receptacles are used, the isolated equipment grounding conductor can terminate at an equipment grounding terminal of the applicable service or derived system in the same building as the receptacle. If the isolated equipment grounding conductor terminates at a separate building, a large voltage difference may exist between buildings during lightning transients. Such transients could cause damage to equipment connected to an isolated-ground-type receptacle and present a shock hazard between the isolated equipment frame and other grounded surfaces.

The informational note to 250.146(D) is a reminder that metallic raceways and boxes are required to be grounded by one of the equipment grounding conductor types specified in 250.118. A wire-type equipment grounding conductor (EGC), in addition to the isolated equipment grounding conductor, could be installed where a nonmetallic raceway is used and the isolated ground receptacle is installed in a metal outlet box that is required to be grounded per 250.148. Similarly, an additional wire-type EGC could be installed where metal outlet boxes are used and flexible metal conduit installed in lengths exceeding 6 ft is the wiring method. Where an ordinary grounding-type receptacle is being replaced with an isolated-ground-type receptacle, use of an existing insulated EGC as the isolated EGC could effectively defeat or seriously compromise the required grounding of the box and raceway if the wiring method does not also qualify as an EGC per 250.118.

## 250.148 Continuity and Attachment of Equipment Grounding Conductors to Boxes

Where circuit conductors are spliced within a box, or terminated on equipment within or supported by a box, any equipment grounding conductor(s) associated with those circuit conductors shall be connected within the box or to the box with devices suitable for the use in accordance with 250.148(A) through (E).

*Exception:* The equipment grounding conductor permitted in 250.146(D) shall not be required to be connected to the other equipment grounding conductors or to the box.

**(A) Connections.** Connections and splices shall be made in accordance with 110.14(B) except that insulation shall not be required.

**(B) Grounding Continuity.** The arrangement of grounding connections shall be such that the disconnection or the removal of a receptacle, luminaire, or other device fed from the box does not interfere with or interrupt the grounding continuity.

**(C) Metal Boxes.** A connection shall be made between the one or more equipment grounding conductors and a metal box by means of a grounding screw that shall be used for no other purpose, equipment listed for grounding, or a listed grounding device.

**(D) Nonmetallic Boxes.** One or more equipment grounding conductors brought into a nonmetallic outlet box shall be arranged such that a connection can be made to any fitting or device in that box requiring grounding.

**(E) Solder.** Connections depending solely on solder shall not be used.

Where a metal box is used in a metal raceway system and there is a wire-type equipment grounding conductor installed in the raceway, 250.148 does not require that the wire-type equipment grounding conductor be connected to the box, provided the box is grounded by the metal raceway and the circuit conductors are not spliced or terminated to equipment in the metal box. A metal box installed at a point in a metal conduit or tubing system to provide a point at which to pull conductors into the raceway system is covered by this section as long as the conductors are not spliced or otherwise terminated in the box. In this respect, the box is treated the same as a metal conduit body such as an “L” or “T” type installed to provide a conductor pull point in a conduit or tubing system.

## VIII. Direct-Current Systems

### 250.160 General

Direct-current systems shall comply with Part VIII and other sections of Article 250 not specifically intended for ac systems.

### 250.162 Direct-Current Circuits and Systems to Be Grounded

Direct-current circuits and systems shall be grounded as provided for in 250.162(A) and (B).

**(A) Two-Wire, Direct-Current Systems.** A 2-wire, dc system supplying premises wiring and operating at greater than 50 volts but not greater than 300 volts shall be grounded.

*Exception No. 1: A system equipped with a ground detector and supplying only industrial equipment in limited areas shall not be required to be grounded.*

*Exception No. 2: A rectifier-derived dc system supplied from an ac system complying with 250.20 shall not be required to be grounded.*

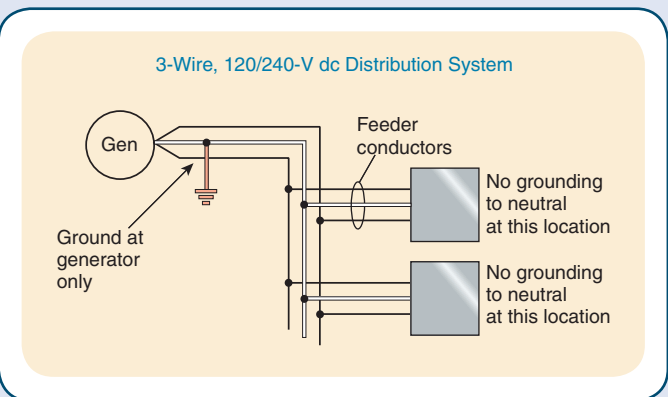

*Exception No. 3: Direct-current fire alarm circuits having a maximum current of 0.030 ampere as specified in Article 760, Part III, shall not be required to be grounded.*

**(B) Three-Wire, Direct-Current Systems.** The neutral conductor of all 3-wire, dc systems supplying premises wiring shall be grounded.

### 250.164 Point of Connection for Direct-Current Systems

**(A) Off-Premises Source.** Direct-current systems to be grounded and supplied from an off-premises source shall have the grounding connection made at one or more supply stations. A grounding connection shall not be made at individual services or at any point on the premises wiring.

As shown in Exhibit 250.60, the neutral of the 3-wire dc distribution system is grounded at the off-premises generator site. Grounding of a 2-wire dc system would be accomplished in the same manner. For an on-premises generator, a grounding connection is required and is to be located at the source of the first system disconnecting means or overcurrent protective device. Other equivalent means that use equipment listed and identified for such use are permitted.

**EXHIBIT 250.60** A 3-wire, 120/240-volt dc distribution system with the neutral grounded at the off-premises generator site.

**(B) On-Premises Source.** Where the dc system source is located on the premises, a grounding connection shall be made at one of the following:

- (1) The source
- (2) The first system disconnection means or overcurrent device
- (3) By other means that accomplish equivalent system protection and that utilize equipment listed and identified for the use

### 250.166 Size of the Direct-Current Grounding Electrode Conductor

The size of the grounding electrode conductor for a dc system shall be as specified in 250.166(A) and (B), except as permitted by 250.166(C) through (E).

**(A) Not Smaller Than the Neutral Conductor.** Where the dc system consists of a 3-wire balancer set or a balancer winding with overcurrent protection as provided in 445.12(D), the grounding electrode conductor shall not be smaller than the neutral conductor and not smaller than 8 AWG copper or 6 AWG aluminum.

**(B) Not Smaller Than the Largest Conductor.** Where the dc system is other than as in 250.166(A), the grounding electrode conductor shall not be smaller than the largest conductor supplied by the system, and not smaller than 8 AWG copper or 6 AWG aluminum.

**(C) Connected to Rod, Pipe, or Plate Electrodes.** Where connected to rod, pipe, or plate electrodes as in 250.52(A)(5) or (A)(7), that portion of the grounding electrode conductor that is the sole connection to the grounding electrode shall not be required to be larger than 6 AWG copper wire or 4 AWG aluminum wire.

**(D) Connected to a Concrete-Encased Electrode.** Where connected to a concrete-encased electrode as in 250.52(A)(3), that portion of the grounding electrode conductor that is the sole connection to the grounding electrode shall not be required to be larger than 4 AWG copper wire.

**(E) Connected to a Ground Ring.** Where connected to a ground ring as in 250.52(A)(4), that portion of the grounding electrode conductor that is the sole connection to the grounding electrode shall not be required to be larger than the conductor used for the ground ring.

### 250.168 Direct-Current System Bonding Jumper

For direct-current systems that are to be grounded, an unspliced bonding jumper shall be used to connect the equipment grounding conductor(s) to the grounded conductor at the source or the first system disconnecting means where the system is grounded. The size of the bonding jumper shall not be smaller than the system grounding electrode conduc-

tor specified in 250.166 and shall comply with the provisions of 250.28(A), (B), and (C).

### 250.169 Ungrounded Direct-Current Separately Derived Systems

Except as otherwise permitted in 250.34 for portable and vehicle-mounted generators, an ungrounded dc separately derived system supplied from a stand-alone power source (such as an engine-generator set) shall have a grounding electrode conductor connected to an electrode that complies with Part III of this article to provide for grounding of metal enclosures, raceways, cables, and exposed non-current-carrying metal parts of equipment. The grounding electrode conductor connection shall be to the metal enclosure at any point on the separately derived system from the source to the first system disconnecting means or overcurrent device, or it shall be made at the source of a separately derived system that has no disconnecting means or overcurrent devices.

The size of the grounding electrode conductor shall be in accordance with 250.166.

## IX. Instruments, Meters, and Relays

### 250.170 Instrument Transformer Circuits

Secondary circuits of current and potential instrument transformers shall be grounded where the primary windings are connected to circuits of 300 volts or more to ground and, where on switchboards, shall be grounded irrespective of voltage.

*Exception No. 1: Circuits where the primary windings are connected to circuits of less than 1000 volts with no live parts or wiring exposed or accessible to other than qualified persons.*

*Exception No. 2: Current transformer secondaries connected in a three-phase delta configuration shall not be required to be grounded.*

### 250.172 Instrument Transformer Cases

Cases or frames of instrument transformers shall be connected to the equipment grounding conductor where accessible to other than qualified persons.

*Exception: Cases or frames of current transformers, the primaries of which are not over 150 volts to ground and that are used exclusively to supply current to meters.*

### 250.174 Cases of Instruments, Meters, and Relays Operating at Less Than 1000 Volts

Instruments, meters, and relays operating with windings or working parts at less than 1000 volts shall be connected to the equipment grounding conductor as specified in 250.174(A), (B), or (C).

**(A) Not on Switchboards.** Instruments, meters, and relays not located on switchboards, operating with windings or working parts at 300 volts or more to ground, and accessible to other than qualified persons, shall have the cases and other exposed metal parts connected to the equipment grounding conductor.

**(B) On Dead-Front Switchboards.** Instruments, meters, and relays (whether operated from current and potential transformers or connected directly in the circuit) on switchboards having no live parts on the front of the panels shall have the cases connected to the equipment grounding conductor.

**(C) On Live-Front Switchboards.** Instruments, meters, and relays (whether operated from current and potential transformers or connected directly in the circuit) on switchboards having exposed live parts on the front of panels shall not have their cases connected to the equipment grounding conductor. Mats of insulating rubber or other suitable floor insulation shall be provided for the operator where the voltage to ground exceeds 150.

### 250.176 Cases of Instruments, Meters, and Relays — Operating Voltage 1 kV and Over

Where instruments, meters, and relays have current-carrying parts of 1 kV and over to ground, they shall be isolated by elevation or protected by suitable barriers, grounded metal, or insulating covers or guards. Their cases shall not be connected to the equipment grounding conductor.

*Exception: Cases of electrostatic ground detectors where the internal ground segments of the instrument are connected to the instrument case and grounded and the ground detector is isolated by elevation.*

### 250.178 Instrument Equipment Grounding Conductor

The equipment grounding conductor for secondary circuits of instrument transformers and for instrument cases shall not be smaller than 12 AWG copper or 10 AWG aluminum. Cases of instrument transformers, instruments, meters, and relays that are mounted directly on grounded metal surfaces of enclosures or grounded metal switchboard panels shall be considered to be grounded, and no additional equipment grounding conductor shall be required.

## X. Grounding of Systems and Circuits of over 1 kV

### 250.180 General

Where systems over 1 kV are grounded, they shall comply with all applicable provisions of the preceding sections of

this article and with 250.182 through 250.190, which supplement and modify the preceding sections.

Part X of Article 250 contains requirements unique to the grounding and bonding of systems and circuits operating at 1 kV and above. The general requirements in Parts I through IX [including the performance requirements in 250.4(A) and (B)] for systems operating under 1 kV also apply to systems 1 kV and over except as modified in Part X. As a general rule, Tables 250.66 (for sizing grounding electrode conductors) and 250.122 (for sizing equipment grounding conductors) apply to systems operating over 1 kV; however, there are special provisions in Part X for equipment grounding conductors for electrical systems utilizing shielded solid dielectric insulated cables rated 2001 to 35,000 volts. These electrical systems are commonly referred as medium and high voltage systems.

### 250.182 Derived Neutral Systems

A system neutral point derived from a grounding transformer shall be permitted to be used for grounding systems over 1 kV.

### 250.184 Solidly Grounded Neutral Systems

Solidly grounded neutral systems shall be permitted to be either single point grounded or multigrounded neutral.

#### (A) Neutral Conductor.

**(1) Insulation Level.** The minimum insulation level for neutral conductors of solidly grounded systems shall be 600 volts.

*Exception No. 1: Bare copper conductors shall be permitted to be used for the neutral conductor of the following:*

- (1) Service-entrance conductors
- (2) Service laterals
- (3) Direct-buried portions of feeders.

*Exception No. 2: Bare conductors shall be permitted for the neutral conductor of overhead portions installed outdoors.*

*Exception No. 3: The grounded neutral conductor shall be permitted to be a bare conductor if isolated from phase conductors and protected from physical damage.*

Informational Note: See 225.4 for conductor covering where within 3.0 m (10 ft) of any building or other structure.

**(2) Ampacity.** The neutral conductor shall be of sufficient ampacity for the load imposed on the conductor but not less than 33⅓ percent of the ampacity of the phase conductors.

*Exception: In industrial and commercial premises under engineering supervision, it shall be permissible to size the ampacity of the neutral conductor to not less than 20 percent of the ampacity of the phase conductor.*

**(B) Single-Point Grounded Neutral System.** Where a single-point grounded neutral system is used, the following shall apply:

- (1) A single-point grounded neutral system shall be permitted to be supplied from (a) or (b):
  - a. A separately derived system
  - b. A multigrounded neutral system with an equipment grounding conductor connected to the multigrounded neutral conductor at the source of the single-point grounded neutral system
- (2) A grounding electrode shall be provided for the system.
- (3) A grounding electrode conductor shall connect the grounding electrode to the system neutral conductor.
- (4) A bonding jumper shall connect the equipment grounding conductor to the grounding electrode conductor.
- (5) An equipment grounding conductor shall be provided to each building, structure, and equipment enclosure.
- (6) A neutral conductor shall only be required where phase-to-neutral loads are supplied.
- (7) The neutral conductor, where provided, shall be insulated and isolated from earth except at one location.
- (8) An equipment grounding conductor shall be run with the phase conductors and shall comply with (a), (b), and (c):
  - a. Shall not carry continuous load
  - b. May be bare or insulated
  - c. Shall have sufficient ampacity for fault current duty

**(C) Multigrounded Neutral Systems.** Where a multigrounded neutral system is used, the following shall apply:

- (1) The neutral conductor of a solidly grounded neutral system shall be permitted to be grounded at more than one point. Grounding shall be permitted at one or more of the following locations:
  - a. Transformers supplying conductors to a building or other structure
  - b. Underground circuits where the neutral conductor is exposed
  - c. Overhead circuits installed outdoors
- (2) The multigrounded neutral conductor shall be grounded at each transformer and at other additional locations by connection to a grounding electrode.
- (3) At least one grounding electrode shall be installed and connected to the multigrounded neutral conductor every 400 m (1300 ft).

- (4) The maximum distance between any two adjacent electrodes shall not be more than 400 m (1300 ft).
- (5) In a multigrounded shielded cable system, the shielding shall be grounded at each cable joint that is exposed to personnel contact.

Sections 250.184(B) and (C) provide two methods, single-point or multigrounded, to solidly ground the neutral in systems operating over 1000 volts. Circuits supplied from a single-point grounded system are required to have an equipment grounding conductor run with the circuit conductors, and this conductor is not to be used as a conductor for continuous line-to-neutral load.

## 250.186 Impedance Grounded Neutral Systems

Impedance grounded neutral systems in which a grounding impedance, usually a resistor, limits the ground-fault current shall be permitted where all of the following conditions are met:

- (1) The conditions of maintenance and supervision ensure that only qualified persons service the installation.
- (2) Ground detectors are installed on the system.
- (3) Line-to-neutral loads are not served.

Impedance grounded neutral systems shall comply with the provisions of 250.186(A) through (D).

**(A) Location.** The grounding impedance shall be inserted in the grounding electrode conductor between the grounding electrode of the supply system and the neutral point of the supply transformer or generator.

**(B) Identified and Insulated.** The neutral conductor of an impedance grounded neutral system shall be identified, as well as fully insulated with the same insulation as the phase conductors.

**(C) System Neutral Conductor Connection.** The system neutral conductor shall not be connected to ground, except through the neutral grounding impedance.

**(D) Equipment Grounding Conductors.** Equipment grounding conductors shall be permitted to be bare and shall be electrically connected to the ground bus and grounding electrode conductor.

## 250.188 Grounding of Systems Supplying Portable or Mobile Equipment

Systems supplying portable or mobile equipment over 1 kV, other than substations installed on a temporary basis, shall comply with 250.188(A) through (F).

**(A) Portable or Mobile Equipment.** Portable or mobile equipment over 1 kV shall be supplied from a system having its neutral conductor grounded through an impedance. Where a delta-connected system over 1 kV is used to supply portable or mobile equipment, a system neutral point and associated neutral conductor shall be derived.

**(B) Exposed Non-Current-Carrying Metal Parts.** Exposed non-current-carrying metal parts of portable or mobile equipment shall be connected by an equipment grounding conductor to the point at which the system neutral impedance is grounded.

**(C) Ground-Fault Current.** The voltage developed between the portable or mobile equipment frame and ground by the flow of maximum ground-fault current shall not exceed 100 volts.

**(D) Ground-Fault Detection and Relaying.** Ground-fault detection and relaying shall be provided to automatically de-energize any component of a system over 1 kV that has developed a ground fault. The continuity of the equipment grounding conductor shall be continuously monitored so as to de-energize automatically the circuit of the system over 1 kV to the portable or mobile equipment upon loss of continuity of the equipment grounding conductor.

**(E) Isolation.** The grounding electrode to which the portable or mobile equipment system neutral impedance is connected shall be isolated from and separated in the ground by at least 6.0 m (20 ft) from any other system or equipment grounding electrode, and there shall be no direct connection between the grounding electrodes, such as buried pipe and fence, and so forth.

**(F) Trailing Cable and Couplers.** Trailing cable and couplers of systems over 1 kV for interconnection of portable or mobile equipment shall meet the requirements of Part III of Article 400 for cables and 490.55 for couplers.

Section 250.188 provides the requirements for portable and mobile high-voltage equipment. *Portable* describes equipment that is easily carried from one location to another. *Mobile* describes equipment that is easily moved on wheels, treads, skids, or similar means.

## 250.190 Grounding of Equipment

**(A) Equipment Grounding.** All non-current-carrying metal parts of fixed, portable, and mobile equipment and associated fences, housings, enclosures, and supporting structures shall be grounded.

*Exception: Where isolated from ground and located such that any person in contact with ground cannot contact such*

*metal parts when the equipment is energized, the metal parts shall not be required to be grounded.*

Informational Note: See 250.110, Exception No. 2, for pole-mounted distribution apparatus.

**(B) Grounding Electrode Conductor.** If a grounding electrode conductor connects non-current-carrying metal parts to ground, the grounding electrode conductor shall be sized in accordance with Table 250.66, based on the size of the largest ungrounded service, feeder, or branch-circuit conductors supplying the equipment. The grounding electrode conductor shall not be smaller than 6 AWG copper or 4 AWG aluminum.

**(C) Equipment Grounding Conductor.** Equipment grounding conductors shall comply with 250.190(C)(1) through (C)(3).

**(1) General.** Equipment grounding conductors that are not an integral part of a cable assembly shall not be smaller than 6 AWG copper or 4 AWG aluminum.

**(2) Shielded Cables.** The metallic insulation shield encircling the current carrying conductors shall be permitted to be used as an equipment grounding conductor, if it is rated for clearing time of ground fault current protective device operation without damaging the metallic shield. The metallic tape insulation shield and drain wire insulation shield shall not be used as an equipment grounding conductor for solidly grounded systems.

Section 250.190(C)(2) permits the metallic shield of a shielded cable to be used as an equipment grounding conductor if it is rated to carry system ground-fault current without damage for the time it takes the ground-fault protective device to clear the fault. However, shields comprised of copper tape and drain wires cannot be used as the equipment grounding conductor in solidly grounded systems. It is necessary to be familiar with different types of shielded cable construction in order to properly apply this provision. The use of shielded cables is specified in 310.10(E) and these provisions are based on the system voltage, installation conditions, and cable construction. As explained in the informational note to 310.10(E), the cable shield provides several different functions related to the safe operation of insulated cables used in medium and high voltage systems. Grounding and bonding are included in those functions.

Exhibit 250.61 shows three different types of single conductor shielded cable construction. Shielded cables are also available in multiconductor configurations such as Type MV (Article 328) or Type MC (Article 330) cables. Where the ground-fault current is relatively low, as is the case with the impedance grounded neutral systems permitted in

**EXHIBIT 250.61** Three examples of single-conductor shielded cable each having a different type of shielding. (Courtesy of Chuck Mello)

250.186, the metallic shield of any of the cable types pictured in Exhibit 250.61 is permitted to serve as the equipment grounding conductor when it is rated for clearing time of ground-fault current without being damaged. Cable manufacturers can provide permissible short-circuit currents for a metallic shield based on fault clearing time of the overcurrent protective device.

However, where the system is solidly grounded, neither the metallic tape insulation shield (top cable shown in Exhibit 250.61) nor the drain wire insulation shield (middle cable shown in Exhibit 250.61) can be used as the equipment grounding conductor, because they do not have sufficient circular mil area to provide the *effective ground fault return path* required by 250.4(A)(5). A metallic insulation shield encircling the conductor (bottom cable shown in Exhibit 250.61) commonly called *concentric neutral cable* has larger conductor strands in the concentric wrap. Because of its larger overall circular mil area, this concentric neutral cable is permitted to be used as an equipment grounding conductor in a solidly grounded system if the metallic shield will not be damaged during the time it takes to open the circuit overcurrent protective device. The copper metallic tape is typically 5 mils thick and is helically applied with a 12.5 percent or larger overlap over the insulation shield. Drain wires are typically 24 AWG bare copper wires. The concentric neutral wires are normally bare or tinned wires with the conductance equivalent of neutral-to-phase conductor for single-conductor cables and typically one-third of the phase conductor for 3-conductor cables.

Where the cable shield cannot (because it is not large enough to carry ground-fault current without damage to shield) or is not permitted to (such as the case with tape or drain wire-type shields) be used as the equipment grounding

conductor, a separate equipment grounding conductor must be installed. The equipment grounding conductor can be integral to a cable assembly, can be run as a separate conductor in a raceway or cable tray, or can be a wiring method-type equipment grounding conductor of one of the types specified in 250.118, such as rigid metal conduit or intermediate metal conduit. Wire-type equipment grounding conductors are sized in accordance with 250.122. See the informational note to 250.190(C)(3) for more information on how the rating of overcurrent protective devices used in systems operating over 1000 volts is determined.

**(3) Sizing.** Equipment grounding conductors shall be sized in accordance with Table 250.122 based on the current rating of the fuse or the overcurrent setting of the protective relay.

**Informational Note:** The overcurrent rating for a circuit breaker is the combination of the current transformer ratio and the current pickup setting of the protective relay.

Section 250.190(C)(3) applies to equipment grounding conductors that are separately installed as specified in 250.190(C)(1) and to a conductor installed in a cable assembly, other than the cable shield, that is used as an equipment grounding conductor. An equipment grounding conductor contained within a cable assembly may be a single conductor or it may be sectioned (comprised of multiple conductors within the cable jacket or sheath to form a single EGC) as permitted by 310.10(H)(5).

## 250.191 Grounding System at Alternating-Current Substations

For ac substations, the grounding system shall be in accordance with Part III of Article 250.

**Informational Note:** For further information on outdoor ac substation grounding, see ANSI/IEEE 80-2000, *IEEE Guide for Safety in AC Substation Grounding*.

  - 280.25 Grounding Electrode Conductor Connections and Enclosures

## I. General

### 280.1 Scope

This article covers general requirements, installation requirements, and connection requirements for surge arresters installed on premises wiring systems over 1 kV.

Voltage surges with peaks of several thousand volts, even on 120-volt circuits, are not uncommon. These surges occur because of induced voltages in power and transmission lines resulting from lightning strikes in the vicinity of the line. Surges also occur as a result of switching inductive circuits on the premises. Surge arresters for installation as part of a premises wiring system are commercially available. The basic standard on surge arresters is ANSI/IEEE C62.11, *Standard for Metal-Oxide Surge Arresters for Alternating-Current Power Systems (> 1 kV)*.

### 280.2 Uses Not Permitted

A surge arrester shall not be installed where the rating of the surge arrester is less than the maximum continuous phase-to-ground power frequency voltage available at the point of application.

### 280.3 Number Required

Where used at a point on a circuit, a surge arrester shall be connected to each ungrounded conductor. A single installation of such surge arresters shall be permitted to protect a number of interconnected circuits, provided that no circuit is exposed to surges while disconnected from the surge arresters.

Means must be provided for protection of circuits that may be disconnected from the generating station bus. A switch

with double-throw action used to disconnect the outside circuits from the station generator and alternatively connect those circuits to ground would satisfy the condition of a single set of arresters protecting more than one circuit.

### 280.4 Surge Arrester Selection

The surge arresters shall comply with 280.4(A) and (B).

**(A) Rating.** The rating of a surge arrester shall be equal to or greater than the maximum continuous operating voltage available at the point of application.

**(1) Solidly Grounded Systems.** The maximum continuous operating voltage shall be the phase-to-ground voltage of the system.

**(2) Impedance or Ungrounded System.** The maximum continuous operating voltage shall be the phase-to-phase voltage of the system.

**(B) Silicon Carbide Types.** The rating of a silicon carbide-type surge arrester shall be not less than 125 percent of the rating specified in 280.4(A).

Informational Note No. 1: For further information on surge arresters, see ANSI/IEEE C62.11-2005, *Standard for Metal-Oxide Surge Arresters for Alternating-Current Power Circuits (>1 kV)*; and ANSI/IEEE C62.22-1997, *Guide for the Application of Metal-Oxide Surge Arresters for Alternating-Current Systems*.

Informational Note No. 2: The selection of a properly rated metal oxide arrester is based on considerations of maximum continuous operating voltage and the magnitude and duration of overvoltages at the arrester location as affected by phase-to-ground faults, system grounding techniques, switching surges, and other causes. See the manufacturer's application rules for selection of the specific arrester to be used at a particular location.

## II. Installation

### 280.11 Location

Surge arresters shall be permitted to be located indoors or outdoors. Surge arresters shall be made inaccessible to unqualified persons, unless listed for installation in accessible locations.

Section 280.11 permits surge arresters to be installed at either an indoor or outdoor location. The location should be chosen to maximize the protection provided by the arrester. Maximum protection is achieved where the surge protective device is located as close as practicable to the equipment

being protected. When a surge passes through an arrester, a wave is reflected in both directions on the conductors connected to the surge arrester. The magnitude of the reflected wave increases as the distance from the arrester increases. If the length of the conductor between the protected equipment and the surge arrester is short, the magnitude of the wave reflected through the equipment is minimized.

### 280.12 Routing of Surge Arrester Grounding Conductors

The conductor used to connect the surge arrester to line, bus, or equipment and to a grounding conductor connection point as provided in 280.21 shall not be any longer than necessary and shall avoid unnecessary bends.

To provide as direct a path to ground as possible, Section 280.12 requires arrester grounding conductors to be as short and as straight as practicable, avoiding any sharp bends and turns, which increase the impedance of the grounding conductor.

## III. Connecting Surge Arresters

### 280.21 Connection

The arrester shall be connected to one of the following:

- (1) Grounded service conductor
- (2) Grounding electrode conductor
- (3) Grounding electrode for the service
- (4) Equipment grounding terminal in the service equipment

### 280.23 Surge-Arrester Conductors

The conductor between the surge arrester and the line and the surge arrester and the grounding connection shall not be smaller than 6 AWG copper or aluminum.

### 280.24 Interconnections

The surge arrester protecting a transformer that supplies a secondary distribution system shall be interconnected as specified in 280.24(A), (B), or (C).

**(A) Metallic Interconnections.** A metallic interconnection shall be made to the secondary grounded circuit conductor or the secondary circuit grounding electrode conductor provided that, in addition to the direct grounding connection at the surge arrester, the following occurs:

**(1) Additional Grounding Connection.** The grounded conductor of the secondary has elsewhere a grounding con-

nection to a continuous metal underground water piping system. In urban water-pipe areas where there are at least four water-pipe connections on the neutral conductor and not fewer than four such connections in each mile of neutral conductor, the metallic interconnection shall be permitted to be made to the secondary neutral conductor with omission of the direct grounding connection at the surge arrester.

**(2) Multigrounded Neutral System Connection.** The grounded conductor of the secondary system is a part of a multigrounded neutral system or static wire of which the primary neutral conductor or static wire has at least four grounding connections in each mile of line in addition to a grounding connection at each service.

**(B) Through Spark Gap or Device.** Where the surge arrester grounding electrode conductor is not connected as in 280.24(A), or where the secondary is not grounded as in 280.24(A) but is otherwise grounded as in 250.52, an interconnection shall be made through a spark gap or listed device as required by 280.24(B)(1) or (B)(2).

**(1) Ungrounded or Unigrounded Primary System.** For ungrounded or unigrounded primary systems, the spark gap or listed device shall have a 60-Hz breakdown voltage of at least twice the primary circuit voltage but not necessarily more than 10 kV, and there shall be at least one other ground on the grounded conductor of the secondary that is not less than 6.0 m (20 ft) distant from the surge-arrester grounding electrode.

**(2) Multigrounded Neutral Primary System.** For multigrounded neutral primary systems, the spark gap or listed device shall have a 60-Hz breakdown of not more than 3 kV, and there shall be at least one other ground on the grounded conductor of the secondary that is not less than 6.0 m (20 ft) distant from the surge-arrester grounding electrode.

**(C) By Special Permission.** An interconnection of the surge-arrester ground and the secondary neutral conductor, other than as provided in 280.24(A) or (B), shall be permitted to be made only by special permission.

### 280.25 Grounding Electrode Conductor Connections and Enclosures

Except as indicated in this article, surge-arrester grounding electrode conductor connections shall be made as specified in Article 250, Parts III and X. Grounding electrode conductors installed in metal enclosures shall comply with 250.64(E).

#### I. General

##### 285.1 Scope

This article covers general requirements, installation requirements, and connection requirements for SPDs [surge arresters and transient voltage surge suppressors (TVSSs)] permanently installed on premises wiring systems 1 kV or less.

Informational Note No. 1: Surge arresters less than 1 kV are also known as Type 1 SPDs.

Informational Note No. 2: Transient voltage surge suppressors (TVSSs) are also known as Type 2 and Type 3 SPDs.

*Surge-protective devices or SPDs covered in Article 285 protect electrical systems operating at 1 kV or less against the effects of surges. Where the SPD will be installed in the premises' wiring system determines the appropriate selection of SPD. Historically, the primary distinction between the devices covered in Articles 280 and 285 was line side*

and load side. Surge arresters were installed on the line side of service or other supply system disconnecting means while TVSSs (the term formerly used for the devices covered in Article 285) were installed on the load side or downstream of the main disconnecting means.

Now the delineation is the voltage rating of the supply system. The designations of SPDs are varied, depending on their location in the premises wiring system. For instance, a Type 1 SPD is permitted to be connected on the supply side of the service or building disconnecting means. These devices were formerly covered by the Article 280 requirements for surge arresters rated 1000 volts or less. Types 2 and 3 SPDs must be installed on the load side of overcurrent protective devices and are the devices formerly referred to by this article as *transient voltage surge suppressors*. Two examples of SPDs are shown in Exhibit 285.1.

**EXHIBIT 285.1** Two SPDs suitable for service-entrance installation, one for direct connection to panelboard busbars and one for mounting in a cabinet or enclosure knockout. (Courtesy of General Electric)

##### 285.3 Uses Not Permitted

An SPD (surge arrester or TVSS) device shall not be installed in the following:

- (1) Circuits exceeding 1 kV
- (2) On ungrounded systems, impedance grounded systems, or corner grounded delta systems unless listed specifically for use on these systems
- (3) Where the rating of the SPD (surge arrester or TVSS) is less than the maximum continuous phase-to-ground power frequency voltage available at the point of application

Informational Note: For further information on SPDs (TVSSs), see NEMA LS 1-1992, *Standard for Low Voltage Surge Suppression Devices*. The selection of a properly rated SPD (TVSS) is based on criteria such as maximum continuous operating voltage, the magnitude and duration of overvoltages at the suppressor location as affected by phase-

to-ground faults, system grounding techniques, and switching surges.

### 285.4 Number Required

Where used at a point on a circuit, the SPD (surge arrester or TVSS) shall be connected to each ungrounded conductor.

### 285.5 Listing

An SPD (surge arrester or TVSS) shall be a listed device.

Section 285.5 requires SPD devices to be listed and UL 1449, *Standard for Surge Protective Devices*, covers Types 1, 2, 3, and 4 devices. SPD devices are permitted to be installed on ungrounded systems, impedance grounded systems, and corner grounded systems where the device is listed for the specific characteristic of the system per 285.3(2).

### 285.6 Short-Circuit Current Rating

The SPD (surge arrester or TVSS) shall be marked with a short-circuit current rating and shall not be installed at a point on the system where the available fault current is in excess of that rating. This marking requirement shall not apply to receptacles.

As specified in 285.6, the marked short-circuit current rating of the SPD has to be equal to or less than the available fault current at the location in the electrical system where the device is installed. In residential and smaller commercial electrical systems, the first SPD is commonly installed either as an integral component of or near to the service-entrance equipment.

Depending on the system voltage, surge protection in larger commercial and industrial electrical systems can be provided by installing a Type 1 SPD (a surge arrester for systems 1 kV and less) or surge arrester (the devices covered in Article 280 for systems over 1 kV) on the line side of the service equipment. Subsequent levels of SPDs are then provided at intermediate points in the distribution system (such as at panelboards that serve loads susceptible to transients) and at the point where utilization equipment connects to the electrical system.

Point-of-use SPDs (e.g., receptacles and permanently installed power strips) may be installed at the equipment (computers, equipment with electronic controls, etc.). The function of a point-of-use SPD is to remove small transients that pass through the more robust surge devices located at the service. Point-of-use SPD devices are also useful in removing small transients that have been generated within the building. See Exhibit 285.2 for a point of use or Type 3 SPD.

**EXHIBIT 285.2** An SPD as an integral component of a receptacle, providing local point-of-use protection of equipment when transient events occur within the facility. (Courtesy of Legrand/Pass & Seymour®)

## II. Installation

### 285.11 Location

SPDs (surge arresters or TVSSs) shall be permitted to be located indoors or outdoors and shall be made inaccessible to unqualified persons, unless listed for installation in accessible locations.

### 285.12 Routing of Connections

The conductors used to connect the SPD (surge arrester or TVSS) to the line or bus and to ground shall not be any longer than necessary and shall avoid unnecessary bends.

In order to optimize performance of SPDs, 285.12 limits the length and routing of the conductor that connects the device to ground. High-frequency currents, such as those common to lightning discharges, tend to reduce the effectiveness of a conductor that connects the device to ground. In addition, as the length of the conductor increases, so does the impedance in the conduction path. This increase drives the clamping voltage higher and reduces the protection provided by the SPD unit. Maximum protection is achieved where the SPD is located as close as practicable to the equipment being protected, as shown in Exhibit 285.3.

**EXHIBIT 285.3** A Type 2 SPD mounted as an integral component of a panelboard, which minimizes conductor length between the electrical system and the SPD. (Courtesy of Schneider Electric)

### III. Connecting SPDs

#### 285.21 Connection

Where an SPD (surge arrester or TVSS) device is installed, it shall comply with 285.23 through 285.28.

Part III of Article 285 covers the location in the electrical system where SPDs are connected. The point in the electrical system where SPDs are connected is dependent on the type of SPD. UL 1449, *Standard for Surge Protection Devices*, is the product standard used to evaluate safe performance of SPDs. In accordance with the scope of UL 1449, a Type 2 SPD must be installed on the load side of the service disconnect overcurrent protection and a Type 3 SPD must be installed on the load side of a branch-circuit overcurrent protective device. The requirement for Type 2 SPDs to be con-

nected on the load side of the first overcurrent protection device in a feeder-supplied structure is necessary due to the exposure of external feeder conductors to a more hostile surge environment such as lightning.

Two requirements in Article 230 permit the installation of SPDs on the line side of the service disconnecting means. First, 230.71(A) permits an additional disconnecting means at the service equipment for surge protective devices installed as part of listed equipment. The disconnecting means for the SPD does not count as one of the six permitted by 230.71(A) where the SPD and its disconnecting means are provided in the listed equipment by the manufacturer. The second is in 230.82(8), in which Type 2 SPDs installed in listed equipment are permitted to be connected on the line side of the service disconnecting means where the SPD is provided with a disconnecting means and overcurrent protection.

#### 285.23 Type 1 SPDs (Surge Arresters)

Type 1 SPDs shall be installed in accordance with 285.23(A) and (B).

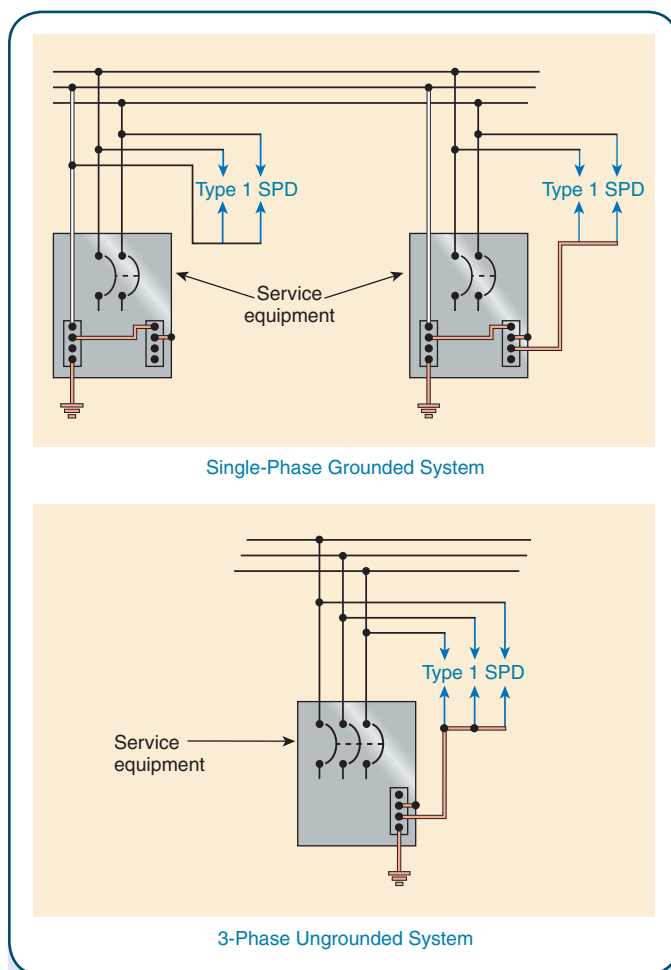

**(A) Installation.** Type 1 SPDs (surge arresters) shall be installed as follows:

- (1) Type 1 SPDs (surge arresters) shall be permitted to be connected to the supply side of the service disconnect as permitted in 230.82(4) or
- (2) Type 1 SPDs (surge arresters) shall be permitted to be connected as specified in 285.24.

**(B) At the Service.** When installed at services, Type 1 SPDs shall be connected to one of the following:

- (1) Grounded service conductor
- (2) Grounding electrode conductor
- (3) Grounding electrode for the service
- (4) Equipment grounding terminal in the service equipment

Single-phase or 3-phase grounded or ungrounded services are permitted by 285.23(A) to have a Type 1 SPD (surge arrester) installed on the line side of the service disconnecting means. Section 285.23(B) then specifies the permitted points of connection for an SPD grounding lead. Although there are four acceptable locations for connecting the SPD grounding lead, it is always necessary to follow the requirement in 285.12 covering the length and physical routing of the conductor that connects the device to ground. See the commentary following 285.12 for more information on the importance of controlling the length and physical routing of the conductor that connects the SPD to ground. Exhibit 285.4 shows three permitted methods of connecting the

**EXHIBIT 285.4** Three methods of connecting Type 1 SPDs (surge arresters) at service equipment.

grounding conductor of a Type 1 SPD at the service equipment. In the upper left diagram, the Type 1 SPD grounding lead is connected to the grounded conductor terminal. In the upper right diagram, the Type 1 SPD grounding lead is connected to the equipment grounding terminal. The lower diagram shows a Type 1 SPD grounding lead connected to the equipment grounding terminal of an ungrounded system. Where used in ungrounded systems, the SPD has to be specifically listed for the application in accordance with 285.3(2).

### 285.24 Type 2 SPDs (TVSSs)

Type 2 SPDs (TVSSs) shall be installed in accordance with 285.24(A) through (C).

**(A) Service-Supplied Building or Structure.** Type 2 SPDs (TVSSs) shall be connected anywhere on the load side of a service disconnect overcurrent device required in 230.91, unless installed in accordance with 230.82(8).

**(B) Feeder-Supplied Building or Structure.** Type 2 SPDs (TVSSs) shall be connected at the building or structure anywhere on the load side of the first overcurrent device at the building or structure.

**(C) Separately Derived System.** The SPD (TVSS) shall be connected on the load side of the first overcurrent device in a separately derived system.

### 285.25 Type 3 SPDs

Type 3 SPDs (TVSSs) shall be permitted to be installed on the load side of branch-circuit overcurrent protection up to the equipment served. If included in the manufacturer's instructions, the Type 3 SPD connection shall be a minimum 10 m (30 ft) of conductor distance from the service or separately derived system disconnect.

### 285.26 Conductor Size

Line and grounding conductors shall not be smaller than 14 AWG copper or 12 AWG aluminum.

### 285.27 Connection Between Conductors

An SPD (surge arrester or TVSS) shall be permitted to be connected between any two conductors — ungrounded conductor(s), grounded conductor, equipment grounding conductor, or grounding electrode conductor. The grounded conductor and the equipment grounding conductor shall be interconnected only by the normal operation of the SPD (surge arrester or TVSS) during a surge.

### 285.28 Grounding Electrode Conductor Connections and Enclosures

Except as indicated in this article, SPD grounding connections shall be made as specified in Article 250, Part III. Grounding electrode conductors installed in metal enclosures shall comply with 250.64(E).

Part III of Article 250, referenced by 285.28, contains the connection rules for grounding electrode conductors and other components of the grounding electrode system. Sections 250.64, 250.68, and 250.70 cover various connections within the grounding electrode system. Section 250.64(E), which is referred to in this section, contains the installation requirements for grounding conductors installed in metal raceway, including the bonding provisions where grounding electrode conductors are installed in ferrous metal raceways. Where routed in a ferrous metal raceway, a grounding electrode conductor associated with an SPD shall be bonded to each end of the raceway if the raceway is not continuous from the enclosure containing the SPD to the grounding electrode. See the commentary following 250.64(E) and Exhibit 250.28.

## I. General Requirements

### 300.1 Scope

**(A) All Wiring Installations.** This article covers wiring methods for all wiring installations unless modified by other articles.

**(B) Integral Parts of Equipment.** The provisions of this article are not intended to apply to the conductors that form an integral part of equipment, such as motors, controllers, motor control centers, or factory assembled control equipment or listed utilization equipment.

Article 300 is one of the fundamental articles of the *NEC*. It covers the wiring requirements for all installations. Requirements for specific wiring methods can be found in the article governing that wiring method in Chapter 3. Chapters 5 through 7 have rules that modify some of the requirements of Article 300. Chapter 8 is not subject to the requirements of Article 300, except where specifically referenced. Article 300 does not have a definitions section. Many of the terms in this article are defined in Article 100.

Section 300.1(B) clarifies that wiring within equipment is not within the scope of this article. Integral wiring of equipment is generally covered by product standards. For example, integral wiring of motors is covered by NEMA MG 1, *Motors and Generators*; integral wiring of industrial control panels by UL 508A, *Standard for Industrial Control Panels*; and wiring that forms an integral part of industrial machinery by NFPA 79, *Electrical Standard for Industrial Machinery*.

**(C) Metric Designators and Trade Sizes.** Metric designators and trade sizes for conduit, tubing, and associated fittings and accessories shall be as designated in Table 300.1(C).

Metric designators for conduits are based on IEC 60981, *Extra-Heavy Duty Rigid Steel Conduits for Electrical Installations*. The metric designators are used for traditional trade size threaded conduit. They do not change the physical dimensions or the traditional “NPT type” threads of the conduit. Metric designators are simply another method of identifying the size of a circular raceway.

Table 300.1(C) identifies a distinct metric designator for each circular raceway trade size. Dimensions or descriptions of circular raceways have traditionally included an inch size as a unit of measure. The unit of measure associated with a circular raceway has not been included in Table 300.1(C) or throughout the *NEC* because it reflects a “modular” or “relative” measure rather than an exact dimension. Many examples of modular or relative measures can be found in the building trades. For example, in North America, items such as a 2 ft × 4 ft drop-in luminaire, an 8 ft fluorescent lamp, and a 2 in. × 4 in. piece of lumber do not reflect true dimensions but rather are loosely associated dimensions common in modular construction. As stated in the footnote to Table 300.1(C), the metric designators and trade sizes are not actual dimensions.

TABLE 300.1(C) Metric Designators and Trade Sizes

Metric Designator	Trade Size
12	3⁄8
16	1⁄2
21	3⁄4
27	1
35	1¼
41	1½
53	2
63	2½
78	3
91	3½
103	4
129	5
155	6

Note: The metric designators and trade sizes are for identification purposes only and are not actual dimensions.

According to Table 4 of Chapter 9, each metric designator sized circular raceway is identical in internal and external dimensions (including manufacturing tolerances) to its trade size counterpart. Therefore, the Informative Annex C wire fill tables are applicable to both metric designator and trade size circular raceways, and so for installation practices, introducing an associated metric designator for traditional circular raceway trade sizes should not be a concern.

However, threaded joints on circular raceways are a concern where the threads do not comply with the product standard. For example, rigid metal conduit (RMC) is required to be listed, according to 344.6, and the appropriate product standard for this listing is UL 6, *Electrical Rigid Metal Conduit — Steel*. Intermediate metal conduit (IMC) is required to be listed, according to 342.6, and the appropriate product standard for this listing is UL 1242, *Standard for Electrical Intermediate Metal Conduit — Steel*. Both listed conduits must be threaded in accordance with ANSI/ASME B.1.20.1-(R 2006), *Pipe Threads, General Purpose (Inch)*. Therefore, only conduits threaded to the traditional dimension of 3⁄4-in. taper per foot are acceptable. Simply stated, although conduit with a metric designator is permitted, an installation using metric threaded conduit is not permitted by the *NEC*. However, an installation using threads according to ANSI/ASME B1.20.1-(R 2006) is in compliance with the *NEC*.

300.2 Limitations

(A) **Voltage.** Wiring methods specified in Chapter 3 shall be used for 600 volts, nominal, or less where not specifically limited in some section of Chapter 3. They shall be permitted for over 600 volts, nominal, where specifically permitted elsewhere in this *Code*.

(B) **Temperature.** Temperature limitation of conductors shall be in accordance with 310.15(A)(3).

Maintaining the temperature of the conductor below its temperature rating depends on environmental factors, as well as not exceeding the termination temperature ratings. See 110.14(C) and its commentary for information on temperature limitations of conductor terminations.

300.3 Conductors

(A) **Single Conductors.** Single conductors specified in Table 310.104(A) shall only be installed where part of a recognized wiring method of Chapter 3.

*Exception: Individual conductors shall be permitted where installed as separate overhead conductors in accordance with 225.6.*

Section 300.3(A) clearly states that building wire, such as individual insulated conductors identified as THHN, is prohibited from use outside of recognized wiring methods. The exception points out two long-time permissions: first, allowing individual conductors as overhead spans and, second, allowing individual conductors as festoon lighting.

(B) **Conductors of the Same Circuit.** All conductors of the same circuit and, where used, the grounded conductor and all equipment grounding conductors and bonding conductors shall be contained within the same raceway, auxiliary gutter, cable tray, cablebus assembly, trench, cable, or cord, unless otherwise permitted in accordance with 300.3(B)(1) through (B)(4).

Section 300.3(B) requires all circuit conductors of an individual circuit to be grouped in order to reduce inductive heating and to avoid increases in overall circuit impedance. A similar rule is found in 300.5(I).

(1) **Paralleled Installations.** Conductors shall be permitted to be run in parallel in accordance with the provisions of 310.10(H). The requirement to run all circuit conductors within the same raceway, auxiliary gutter, cable tray, trench, cable, or cord shall apply separately to each portion of the paralleled installation, and the equipment grounding conductors shall comply with the provisions of 250.122. Parallel runs in cable tray shall comply with the provisions of 392.20(C).

*Exception: Conductors installed in nonmetallic raceways run underground shall be permitted to be arranged as iso-*

*lated phase installations. The raceways shall be installed in close proximity, and the conductors shall comply with the provisions of 300.20(B).*

**(2) Grounding and Bonding Conductors.** Equipment grounding conductors shall be permitted to be installed outside a raceway or cable assembly where in accordance with the provisions of 250.130(C) for certain existing installations or in accordance with 250.134(B), Exception No. 2, for dc circuits. Equipment bonding conductors shall be permitted to be installed on the outside of raceways in accordance with 250.102(E).

**(3) Nonferrous Wiring Methods.** Conductors in wiring methods with a nonmetallic or other nonmagnetic sheath, where run in different raceways, auxiliary gutters, cable trays, trenches, cables, or cords, shall comply with the provisions of 300.20(B). Conductors in single-conductor Type MI cable with a nonmagnetic sheath shall comply with the provisions of 332.31. Conductors of single-conductor Type MC cable with a nonmagnetic sheath shall comply with the provisions of 330.31, 330.116, and 300.20(B).

**(4) Enclosures.** Where an auxiliary gutter runs between a column-width panelboard and a pull box, and the pull box includes neutral terminations, the neutral conductors of circuits supplied from the panelboard shall be permitted to originate in the pull box.

Section 300.3(B)(4) recognizes the practice of supplying a narrow, column-type or column-width panelboard through an auxiliary gutter from an overhead pull box and running only the ungrounded conductors down from the pull box to the panelboard.

### (C) Conductors of Different Systems.

**(1) 600 Volts, Nominal, or Less.** Conductors of ac and dc circuits, rated 600 volts, nominal, or less, shall be permitted to occupy the same equipment wiring enclosure, cable, or raceway. All conductors shall have an insulation rating equal to at least the maximum circuit voltage applied to any conductor within the enclosure, cable, or raceway.

Informational Note No. 1: See 725.136(A) for Class 2 and Class 3 circuit conductors.

Informational Note No. 2: See 690.4(B) for photovoltaic source and output circuits.

Section 300.3(C)(1) makes it clear that the maximum circuit voltage in the raceway, not the maximum insulation voltage rating of the conductors in the raceway, is what determines the minimum voltage rating required for the insulation of conductors for systems of 600 volts or less.

### Application Example

The conductors of a 3-phase, 4-wire, 208Y/120-volt ac circuit; a 3-phase, 4-wire, 480Y/277-volt ac circuit; and a 3-wire, 120/240-volt dc circuit may occupy the same equipment wiring enclosure, cable, or raceway if all the conductors are insulated for the maximum circuit voltage of any conductor. In this case, the maximum circuit voltage is 480 volts, and 600-volt insulation would be suitable for all the conductors.

If a 2-wire, 120-volt circuit is included in the same raceway with a 3-wire, 120/240-volt circuit having 600-volt conductors, the 2-wire, 120-volt circuit conductors could use 300-volt insulation because the maximum circuit voltage is only 240 volts.

Informational Note No. 2 to 300.3(C)(1) references 690.4(B), which prohibits the location of solar photovoltaic circuits within the same enclosure as conductors of other systems unless the conductors are separated by a partition or are connected together. Additionally, 700.10(B) requires circuit wiring for emergency systems to be kept entirely independent of all other wiring and equipment.

**(2) Over 600 Volts, Nominal.** Conductors of circuits rated over 600 volts, nominal, shall not occupy the same equipment wiring enclosure, cable, or raceway with conductors of circuits rated 600 volts, nominal, or less unless otherwise permitted in (C)(2)(a) through (C)(2)(e).

(a) Secondary wiring to electric-discharge lamps of 1000 volts or less, if insulated for the secondary voltage involved, shall be permitted to occupy the same luminaire, sign, or outline lighting enclosure as the branch-circuit conductors.

(b) Primary leads of electric-discharge lamp ballasts insulated for the primary voltage of the ballast, where contained within the individual wiring enclosure, shall be permitted to occupy the same luminaire, sign, or outline lighting enclosure as the branch-circuit conductors.

(c) Excitation, control, relay, and ammeter conductors used in connection with any individual motor or starter shall be permitted to occupy the same enclosure as the motor-circuit conductors.

(d) In motors, switchgear and control assemblies, and similar equipment, conductors of different voltage ratings shall be permitted.

(e) In manholes, if the conductors of each system are permanently and effectively separated from the conductors of the other systems and securely fastened to racks, insulators, or other approved supports, conductors of different voltage ratings shall be permitted.

Conductors having nonshielded insulation and operating at different voltage levels shall not occupy the same enclosure, cable, or raceway.

### 300.4 Protection Against Physical Damage

Where subject to physical damage, conductors, raceways, and cables shall be protected.

#### (A) Cables and Raceways Through Wood Members.

This section was revised for the 2011 *Code* to make it clear that raceways and cables must be protected where subject to physical damage.

**(1) Bored Holes.** In both exposed and concealed locations, where a cable- or raceway-type wiring method is installed through bored holes in joists, rafters, or wood members, holes shall be bored so that the edge of the hole is not less than 32 mm (1¼ in.) from the nearest edge of the wood member. Where this distance cannot be maintained, the cable or raceway shall be protected from penetration by screws or nails by a steel plate(s) or bushing(s), at least 1.6 mm (⅙ in.) thick, and of appropriate length and width installed to cover the area of the wiring.

*Exception No. 1: Steel plates shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.*

*Exception No. 2: A listed and marked steel plate less than 1.6 mm (⅙ in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.*

The intent of 300.4(A)(1) is to prevent nails and screws from being driven into conductors, cables, and raceways. As shown in Exhibit 300.1, where the edge of a drilled hole is less than 1¼ in. from the nearest edge of a wood stud, a ⅙ in. thick steel plate, or a listed steel plate less than ⅙ in. thick but providing equivalent protection, is required to prevent screws or nails from penetrating the stud far enough to injure a cable. Where a single metal plate does not provide for the protection of a cable, multiple steel plates are required. Building codes limit the maximum size of bored or notched holes in studs, and 300.4(A)(2) indicates that consideration should be given to the size of notches in studs, so as not to affect the strength of the structure.

Exception No. 1 to 300.4(A)(1) and Exception No. 1 to 300.4(A)(2) permit intermediate metal conduit, rigid metal conduit, rigid polyvinyl chloride conduit, and electrical metallic tubing to be installed through bored holes or laid in notches less than 1¼ in. from the nearest edge of the stud, without using a steel plate or bushing. Exception No. 2 to

**EXHIBIT 300.1** A listed and marked steel plate used to protect a nonmetallic-sheathed cable less than 1¼ in. from the edge of a wood stud. A steel plate is permitted to be less than ⅙ in. only if it is listed and marked, thus meeting the requirements of Exception No. 2 to both 300.4(A)(1) and (A)(2). (Courtesy of Hubbell RACO)

300.4(A)(1) and Exception No. 2 to 300.4(A)(2) permit steel plates thinner than ⅙ in. to protect cables and raceways, but only if the plates are specifically listed and marked.

**(2) Notches in Wood.** Where there is no objection because of weakening the building structure, in both exposed and concealed locations, cables or raceways shall be permitted to be laid in notches in wood studs, joists, rafters, or other wood members where the cable or raceway at those points is protected against nails or screws by a steel plate at least 1.6 mm (⅙ in.) thick, and of appropriate length and width, installed to cover the area of the wiring. The steel plate shall be installed before the building finish is applied.

*Exception No. 1: Steel plates shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.*

*Exception No. 2: A listed and marked steel plate less than 1.6 mm (⅙ in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.*

#### (B) Nonmetallic-Sheathed Cables and Electrical Nonmetallic Tubing Through Metal Framing Members.

**(1) Nonmetallic-Sheathed Cable.** In both exposed and concealed locations where nonmetallic-sheathed cables pass through either factory- or field-punched, cut, or drilled slots or holes in metal members, the cable shall be protected by listed bushings or listed grommets covering all metal edges

that are securely fastened in the opening prior to installation of the cable.

The requirements of 300.4(B) afford physical protection for nonmetallic-sheathed cables as the cables are pulled through the openings in metal studs. This section also mandates that all metal studs be positioned in place before cable is pulled through protected openings. Fastening the listed grommet or listed bushing in place prior to installing cable is also mandatory. Should additional metal studs become necessary after installation of a cable, the cable must be removed before the stud is added. Field notching of metal studs and then installing the stud around a nonmetallic sheathed cable already installed or in place can lead to cable damage and can result in insulation failure.

**(2) Nonmetallic-Sheathed Cable and Electrical Nonmetallic Tubing.** Where nails or screws are likely to penetrate nonmetallic-sheathed cable or electrical nonmetallic tubing, a steel sleeve, steel plate, or steel clip not less than 1.6 mm ( $\frac{1}{16}$  in.) in thickness shall be used to protect the cable or tubing.

*Exception: A listed and marked steel plate less than 1.6 mm ( $\frac{1}{16}$  in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.*

This exception permits the use of steel plates thinner than  $\frac{1}{16}$  in. to protect cables and raceways, but only if the plates are specifically listed and marked.

**(C) Cables Through Spaces Behind Panels Designed to Allow Access.** Cables or raceway-type wiring methods, installed behind panels designed to allow access, shall be supported according to their applicable articles.

Cable- or raceway-type wiring installed above suspended ceilings with lift-up panels must not be laid on the suspended ceiling so as to inhibit access. Such wiring is required to be supported according to 300.11(A), 300.23, and the requirements of the article applicable to the wiring method involved.

Similarly, low-voltage, optical fiber, broadband, and communications cables are not permitted to block access to equipment above the suspended ceiling. Examples of this requirement are also found in 725.21, 760.21, 770.21, 800.21, 820.21, and 830.21. For support of low-voltage cables, optical fiber, broadband, and communications cables, see 720.11, 725.24, 760.24, 770.24, 800.24, 820.24, and 830.24.

**(D) Cables and Raceways Parallel to Framing Members and Furring Strips.** In both exposed and concealed locations, where a cable- or raceway-type wiring method is installed parallel to framing members, such as joists, rafters, or studs, or is installed parallel to furring strips, the cable or raceway shall be installed and supported so that the nearest outside surface of the cable or raceway is not less than 32 mm ( $1\frac{1}{4}$  in.) from the nearest edge of the framing member or furring strips where nails or screws are likely to penetrate. Where this distance cannot be maintained, the cable or raceway shall be protected from penetration by nails or screws by a steel plate, sleeve, or equivalent at least 1.6 mm ( $\frac{1}{16}$  in.) thick.

The intent of 300.4(D) is to prevent mechanical damage to cables and raceways from nails and screws. This section recognizes that cables and raceways need the same level of physical protection at furring strips as they do at framing members, and offers two means of protection that generally apply to exposed or concealed work. The first method, shown in Exhibit 300.2, is to position the NM cables to equal or exceed the minimum clear distance of  $1\frac{1}{4}$  in. that is required between the furring strip (wood strapping in this case) and the nearest edge of the NM cable. Exhibit 300.3 illustrates the NM cable installed parallel to framing members and fastened to maintain at least  $1\frac{1}{4}$  in. clear space from the edge. The second method permits the cable or raceway to be installed closer than  $1\frac{1}{4}$  in. from the edge of the framing member if physical protection, such as a steel plate, its equivalent, or a sleeve, is provided. (A steel plate is illustrated in Exhibit 300.1.)

**EXHIBIT 300.2** Nonmetallic sheathed cables adjacent to furring strips in a wood frame structure in accordance with 300.4(D).

**EXHIBIT 300.3** Cables and raceways installed parallel to framing members in accordance with 300.4(D).

*Exception No. 1: Steel plates, sleeves, or the equivalent shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.*

*Exception No. 2: For concealed work in finished buildings, or finished panels for prefabricated buildings where such supporting is impracticable, it shall be permissible to fish the cables between access points.*

*Exception No. 3: A listed and marked steel plate less than 1.6 mm ( $\frac{1}{16}$  in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.*

As stated in Exception No. 1 to 300.4(D), the steel plate requirement does not apply to rigid metal conduit, rigid non-metallic conduit, intermediate metal conduit, or electrical metallic tubing wiring methods because those wiring methods provide physical protection for the conductors. Exception No. 3 permits the use of steel plates thinner than  $\frac{1}{16}$  in.

to protect cables and raceways, but only if the plates are specifically listed and marked.

**(E) Cables, Raceways, or Boxes Installed in or Under Roof Decking.** A cable, raceway, or box, installed in exposed or concealed locations under metal-corrugated sheet roof decking, shall be installed and supported so there is not less than 38 mm ( $1\frac{1}{2}$  in.) measured from the lowest surface of the roof decking to the top of the cable, raceway, or box. A cable, raceway, or box shall not be installed in concealed locations in metal-corrugated, sheet decking-type roof.

**Informational Note:** Roof decking material is often repaired or replaced after the initial raceway or cabling and roofing installation and may be penetrated by the screws or other mechanical devices designed to provide “hold down” strength of the waterproof membrane or roof insulating material.

*Exception: Rigid metal conduit and intermediate metal conduit shall not be required to comply with 300.4(E).*

This section was revised for the 2011 *Code* to recognize that boxes may also be damaged by nail penetration. For cables, raceways, and boxes installed below a metal-corrugated sheet roof decking installation, 300.4(E) requires at least  $1\frac{1}{2}$  in. of separation from any of the roof decking surface, as illustrated in Exhibit 300.4. The  $1\frac{1}{2}$  in. dimension is measured from the lowest point of the roof deck to the top surface of the cable, raceway, or box. The section was also revised to prohibit the cables, raceways, or boxes from being installed above in the space between the metal deck and the roofing material.

The informational note clarifies that this spacing is required to avoid future damage when the roofing is repaired

1. Roofing material
2. Metal-corrugated sheet roof decking
3. Only RMC and IMC permitted within  $1\frac{1}{2}$  in. of roof decking
4. Steel or wood joists
5. Any wiring method or box permitted within or below the roof framing where installed not less than  $1\frac{1}{2}$  in. below the nearest point of the metal corrugated roof decking surface.

**EXHIBIT 300.4** Placement of cables and raceways under metal-corrugated sheet roof decking to avoid physical damage according to 300.4(E).

or replaced. Roof replacement materials are fastened in place with long screws from atop the roof. These fasteners usually penetrate the roof decking installation and could continue into cables and raceways installed below. Adequate space between the corrugated sheet metal roof deck installation and the cables and raceways below the deck will prevent future damage to the cable or raceway installation. The exception to 300.4(E) clarifies that this requirement does not apply to more robust metal raceways such as rigid metal conduit (RMC) and intermediate metal conduit (IMC).

**(F) Cables and Raceways Installed in Shallow Grooves.**

Cable- or raceway-type wiring methods installed in a groove, to be covered by wallboard, siding, paneling, carpeting, or similar finish, shall be protected by 1.6 mm ( $\frac{1}{16}$  in.) thick steel plate, sleeve, or equivalent or by not less than 32-mm ( $1\frac{1}{4}$ -in.) free space for the full length of the groove in which the cable or raceway is installed.

*Exception No. 1: Steel plates, sleeves, or the equivalent shall not be required to protect rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing.*

*Exception No. 2: A listed and marked steel plate less than 1.6 mm ( $\frac{1}{16}$  in.) thick that provides equal or better protection against nail or screw penetration shall be permitted.*

**(G) Insulated Fittings.** Where raceways contain 4 AWG or larger insulated circuit conductors, and these conductors enter a cabinet, a box, an enclosure, or a raceway, the conductors shall be protected by an **identified** fitting providing a smoothly rounded insulating surface, unless the conductors are separated from the fitting or raceway by **identified** insulating material that is securely fastened in place.

*Exception: Where threaded hubs or bosses that are an integral part of a cabinet, box, enclosure, or raceway provide a smoothly rounded or flared entry for conductors.*

Heavy conductors and cables tend to stress the conductor insulation at raceway terminating points. Section 300.4(G) requires insulated bushing or smooth rounded entries at raceway and cable terminations to reduce the risk of insulation failure at conductor insulation stress points. The temperature ratings of insulating bushing must coordinate with the insulation of the conductor to ensure that the protection remains intact over the life cycle of the insulated conductor.

Listed insulating bushings, whether provided separately or as part of a fitting, are colored black or brown if they are suitable for a temperature of 150°C, and any other color for

90°C, unless specifically marked for a higher temperature. Exhibit 300.5 shows an insulated thermoplastic or fiber bushing used to protect the conductors from chafing against a metal conduit fitting. Note the use of a double locknut, one on the inside and one on the outside of the enclosure. The locknuts are necessary because the raceway cannot be secured by the fiber or plastic bushing.

**EXHIBIT 300.5** An insulated bushing used to protect conductors from chafing against a metal conduit fitting in accordance with 300.4(G).

The main rule in 300.4(G) applies generally to all wiring methods and all enclosures. See also 342.46, 344.46, and 352.46 for further information relating to bushings.

Conduit bushings constructed wholly of insulating material shall not be used to secure a fitting or raceway. The insulating fitting or insulating material shall have a temperature rating not less than the insulation temperature rating of the installed conductors.

**(H) Structural Joints.** A listed expansion/deflection fitting or other approved means shall be used where a raceway crosses a structural joint intended for expansion, contraction or deflection, used in buildings, bridges, parking garages, or other structures.

Section 300.4(H) is new in the 2011 Code. Raceways can be damaged when improperly installed in structural construction joints leaving conductors or cables exposed. Structural construction joints can experience shear and lateral loads due to gravity, expansion and contraction, and movement of the structure. Listed expansion/deflection fittings are available for use at structural joints. However, other approved means of protecting the integrity of the raceways system are also permitted.

### 300.5 Underground Installations

**(A) Minimum Cover Requirements.** Direct-buried cable or conduit or other raceways shall be installed to meet the minimum cover requirements of Table 300.5.

The requirements for direct-buried conductors and raceways are given in 300.5(A) and Table 300.5. As noted in Column 4 of Table 300.5, conductors under residential driveways must be at least 18 in. below grade. However, if the conductors are protected by an overcurrent device rated at not more than 20 amperes and provided with ground-fault circuit-interrupter (GFCI) protection for personnel, the burial depth may be reduced to 12 in. Exhibits 300.6 and 300.7 show examples of underground installations of 18 in. and 12 in., respectively. See 300.50 where circuits exceed 600 volts.

**EXHIBIT 300.6** Rigid polyvinyl chloride conduit, Type PVC, buried in compliance with Column 3 of Table 300.5 and 300.5(A).

**(B) Wet Locations.** The interior of enclosures or raceways installed underground shall be considered to be a wet location. Insulated conductors and cables installed in these enclosures or raceways in underground installations shall be listed for use in wet locations and shall comply with 310.10(C). Any connections or splices in an underground installation shall be approved for wet locations.

Section 300.5(B) requires that the inside of all raceways and enclosures installed underground be classified as a wet loca-

**EXHIBIT 300.7** A 20-ampere, GFCI-protected residential branch circuit installed with a minimum burial depth of 12 in. beneath a residential driveway per Table 300.5.

tion. Conductors installed in such underground locations must be listed for use in wet locations and comply with 310.10(C).

**(C) Underground Cables Under Buildings.** Underground cable installed under a building shall be in a raceway.

*Exception No. 1: Type MI Cable shall be permitted under a building without installation in a raceway where embedded in concrete, fill, or other masonry in accordance with 332.10(6) or in underground runs where suitably protected against physical damage and corrosive conditions in accordance with 332.10(10).*

*Exception No. 2: Type MC Cable listed for direct burial or concrete encasement shall be permitted under a building without installation in a raceway in accordance with 330.10(A)(5) and in wet locations in accordance with 330.10(11).*

This section was revised for the 2011 Code with the addition of the two exceptions. The main rule is that underground cable installed under a building must be installed in a suitable raceway.

**(D) Protection from Damage.** Direct-buried conductors and cables shall be protected from damage in accordance with 300.5(D)(1) through (D)(4).

**TABLE 300.5 Minimum Cover Requirements, 0 to 600 Volts, Nominal, Burial in Millimeters (Inches)**

Type of Wiring Method or Circuit										
Location of Wiring Method or Circuit	Column 1 Direct Burial Cables or Conductors		Column 2 Rigid Metal Conduit or Intermediate Metal Conduit		Column 3 Nonmetallic Raceways Listed for Direct Burial Without Concrete Encasement or Other Approved Raceways		Column 4 Residential Branch Circuits Rated 120 Volts or Less with GFCI Protection and Maximum Overcurrent Protection of 20 Amperes		Column 5 Circuits for Control of Irrigation and Landscape Lighting Limited to Not More Than 30 Volts and Installed with Type UF or in Other Identified Cable or Raceway	
	mm	in.	mm	in.	mm	in.	mm	in.	mm	in.
All locations not specified below	600	24	150	6	450	18	300	12	150	6
In trench below 50-mm (2-in.) thick concrete or equivalent	450	18	150	6	300	12	150	6	150	6
Under a building	0 (in raceway or Type MC or Type MI cable identified for direct burial)	0	0	0	0	0	0 (in raceway or Type MC or Type MI cable identified for direct burial) )	0	0 (in raceway or Type MC or Type MI cable identified for direct burial) )	0
Under minimum of 102-mm (4-in.) thick concrete exterior slab with no vehicular traffic and the slab extending not less than 152 mm (6 in.) beyond the underground installation	450	18	100	4	100	4	150 (direct burial) 100 (in raceway)	6 4	150 (direct burial) 100 (in raceway)	6 4

One- and two-family dwelling driveways and outdoor parking areas, and used only for dwelling-related purposes	450	18	450	18	450	18	300	12	450	18
In or under airport runways, including adjacent areas where trespassing prohibited	450	18	450	18	450	18	450	18	450	18

**Notes:**

1. Cover is defined as the shortest distance in millimeters (inches) measured between a point on the top surface of any direct-buried conductor, cable, conduit, or other raceway and the top surface of finished grade, concrete, or similar cover.
2. Raceways approved for burial only where concrete encased shall require concrete envelope not less than 50 mm (2 in.) thick.
3. Lesser depths shall be permitted where cables and conductors rise for terminations or splices or where access is otherwise required.
4. Where one of the wiring method types listed in Columns 1–3 is used for one of the circuit types in Columns 4 and 5, the shallowest depth of burial shall be permitted.
5. Where solid rock prevents compliance with the cover depths specified in this table, the wiring shall be installed in metal or nonmetallic raceway permitted for direct burial. The raceways shall be covered by a minimum of 50 mm (2 in.) of concrete extending down to rock.

**(1) Emerging from Grade.** Direct-buried conductors and cables emerging from grade and specified in columns 1 and 4 of Table 300.5 shall be protected by enclosures or raceways extending from the minimum cover distance below grade required by 300.5(A) to a point at least 2.5 m (8 ft) above finished grade. In no case shall the protection be required to exceed 450 mm (18 in.) below finished grade.

**(2) Conductors Entering Buildings.** Conductors entering a building shall be protected to the point of entrance.

**(3) Service Conductors.** Underground service conductors that are not encased in concrete and that are buried 450 mm (18 in.) or more below grade shall have their location identified by a warning ribbon that is placed in the trench at least 300 mm (12 in.) above the underground installation.

The warning ribbon required in 300.5(D)(3) reduces the risk of an accident, an electrocution, or an arc-flash incident during excavation near underground service conductors that are not encased in concrete. This provision does not extend to feeders and branch circuits, because these circuits contain short-circuit and overload protection.

**(4) Enclosure or Raceway Damage.** Where the enclosure or raceway is subject to physical damage, the conductors shall be installed in rigid metal conduit, intermediate metal conduit, Schedule 80 PVC conduit, or equivalent.

**(E) Splices and Taps.** Direct-buried conductors or cables shall be permitted to be spliced or tapped without the use of splice boxes. The splices or taps shall be made in accordance with 110.14(B).

Underground splices are not required to be in a box where made in accordance with 110.14(B), which requires the splicing means to be listed for underground use. Sealed wire connector systems are listed for underground splicing. They restore the insulation integrity of the spliced conductors in a permanent joint. Sealed wire connectors are used where it will not be necessary to access the splices in the future.

A difference exists between multiconductor cables labeled for direct burial and single conductors labeled for direct burial. Because direct-burial multiconductor cables may or may not contain individual conductors labeled for direct burial, the overall cable jacket may be the only underground protection technique for the contained conductors. Although the direct-burial splicing techniques used on multiconductor cables can differ widely from the techniques used on direct-

burial single-conductor cables, the *Code* requirements are generally the same. The splicing technique must be listed for the cable type and listed for direct burial. See 250.8 for spliced grounding and bonding conductors. An example of a sealed wire connector system listed for direct burial used to splice single-conductor installed underground cables is shown in Exhibit 300.8.

**EXHIBIT 300.8** One underground splicing method in accordance with 300.5(E) as well as 110.14(C). (Courtesy of 3M Co., Electrical Markets Division)

**(F) Backfill.** Backfill that contains large rocks, paving materials, cinders, large or sharply angular substances, or corrosive material shall not be placed in an excavation where materials may damage raceways, cables, or other substructures or prevent adequate compaction of fill or contribute to corrosion of raceways, cables, or other substructures.

Where necessary to prevent physical damage to the raceway or cable, protection shall be provided in the form of granular or selected material, suitable running boards, suitable sleeves, or other approved means.

**(G) Raceway Seals.** Conduits or raceways through which moisture may contact live parts shall be sealed or plugged at either or both ends.

**Informational Note:** Presence of hazardous gases or vapors may also necessitate sealing of underground conduits or raceways entering buildings.

Section 300.5(G) requires either or both ends of conduits and raceways subject to moisture to be sealed or plugged. One method, shown in Exhibit 300.9, is a conduit sealing bushing that prevents the entrance of gas or moisture. See 230.8 for sealing service raceways.

**EXHIBIT 300.9** A conduit sealing bushing used to prevent the entrance of gas or moisture, in compliance with 300.5(G). (Redrawn courtesy of O-Z/Gedney, a division of EGS Electrical Group)

**(H) Bushing.** A bushing, or terminal fitting, with an integral bushed opening shall be used at the end of a conduit or other raceway that terminates underground where the conductors or cables emerge as a direct burial wiring method. A seal incorporating the physical protection characteristics of a bushing shall be permitted to be used in lieu of a bushing.

Where a conduit or raceway terminates underground and emerges as a direct-burial wiring method, 300.5(H) requires a protective fitting. Exhibit 300.10 shows such a fitting with a Type UF cable buried in compliance with Table 300.5. Note the protective bushing where the cable is used with metal conduit. The bushing will protect the cable from damage by the conduit. Metal conduit is usually used as this fitting because of the potential to damage a nonmetallic conduit when pulling conductors in an underground installa-

**EXHIBIT 300.10** A Type UF cable buried in compliance with Table 300.5.

tion. See 300.10, Exception No. 1. See also the commentary following 300.4(G).

**(I) Conductors of the Same Circuit.** All conductors of the same circuit and, where used, the grounded conductor and all equipment grounding conductors shall be installed in the same raceway or cable or shall be installed in close proximity in the same trench.

*Exception No. 1: Conductors shall be permitted to be installed in parallel in raceways, multiconductor cables, or direct-buried single conductor cables. Each raceway or multiconductor cable shall contain all conductors of the same circuit, including equipment grounding conductors. Each direct-buried single conductor cable shall be located in close proximity in the trench to the other single conductor cables in the same parallel set of conductors in the circuit, including equipment grounding conductors.*

Keeping all circuit conductors together reduces inductive heating and reduces circuit impedance. Section 300.5(I), Exception No. 1, permits the installation of paralleled conductors in different raceways provided all circuit conductors, including equipment grounding conductors, are installed in each of the parallel raceways. Conductors of the same circuit are addressed in 300.3(B). Also see 310.10(H) for conductors in parallel. This exception was revised for the 2011 Code to make it clear that it covers single conductors, as well as multiconductor underground cables.

*Exception No. 2: Isolated phase, polarity, grounded conductor, and equipment grounding and bonding conductor installations shall be permitted in nonmetallic raceways or cables with a nonmetallic covering or nonmagnetic sheath in close proximity where conductors are paralleled as permitted in 310.10(H), and where the conditions of 300.20(B) are met.*

Isolated phase installations contain only one phase per raceway or cable. The spacing between isolated phase raceways and cables should be as small as possible, and the length of the run limited, to avoid increased circuit impedance and the resulting increase in voltage drop inherent in an installation involving ac circuits. Isolated phase installations may be used in ac circuits to limit available fault current at downstream equipment.

Isolated phase installations present an inherent hazard of overheating, a risk that must be understood and carefully controlled. This hazard results from induced currents in metal surrounding a raceway that contains only one phase

conductor. [See 300.20(A) and (B) for more information on induced currents in raceways.] The surrounding metal acts as a shorted transformer turn. In underground installations, a single conductor is unlikely to be installed in a metal raceway or, if it were, is unlikely to present a fire hazard. This is not true, however, for aboveground raceways, and it is the reason isolated phase installations have limited application for aboveground installations.

See 300.3(B)(3) together with 330.31 and 332.31, which recognize single-conductor Type MI cable and single-conductor Type MC cable.

**(J) Earth Movement.** Where direct-buried conductors, raceways, or cables are subject to movement by settlement or frost, direct-buried conductors, raceways, or cables shall be arranged so as to prevent damage to the enclosed conductors or to equipment connected to the raceways.

**Informational Note:** This section recognizes “S” loops in underground direct burial to raceway transitions, expansion fittings in raceway risers to fixed equipment, and, generally, the provision of flexible connections to equipment subject to settlement or frost heaves.

Section 300.5(J) requires that an installation be designed to allow for movement of direct-buried equipment, cables, and raceways. Slack must be allowed in cables or expansion joints, or other measures must be taken, if earth movement due to frost or settlement is anticipated.

**(K) Directional Boring.** Cables or raceways installed using directional boring equipment shall be approved for the purpose.

Metal and nonmetallic raceways for underground boring-type installations are required by 300.5(K) to be approved for such use. There are a number of metal and nonmetallic raceways that are suitable for boring installations, such as high density polyethylene conduit (Type HDPE). See Article 353 for more information.

### 300.6 Protection Against Corrosion and Deterioration

Raceways, cable trays, cablebus, auxiliary gutters, cable armor, boxes, cable sheathing, cabinets, elbows, couplings, fittings, supports, and support hardware shall be of materials suitable for the environment in which they are to be installed.

Section 300.6 correlates with the requirement in 110.11 that equipment be suitable for the environment in which it is in-

stalled. Section 300.6 applies generally. For specific applications, it is necessary to review manufacturers' information as well as the particular *Code* article that addresses the wiring method and equipment under consideration.

**(A) Ferrous Metal Equipment.** Ferrous metal raceways, cable trays, cablebus, auxiliary gutters, cable armor, boxes, cable sheathing, cabinets, metal elbows, couplings, nipples, fittings, supports, and support hardware shall be suitably protected against corrosion inside and outside (except threads at joints) by a coating of approved corrosion-resistant material. Where corrosion protection is necessary and the conduit is threaded in the field, the threads shall be coated with an approved electrically conductive, corrosion-resistant compound.

Section 300.6(A) requires ferrous metal equipment be protected from corrosion with an approved anti-corrosion compound, such as the example shown in Exhibit 300.11.

**EXHIBIT 300.11** KOPR-Shield® (a registered trademark of Jet Lube), a conductive anti-corrosion surface compound suitable for application on field-cut conduit threads where protection from corrosion is necessary according to 300.6(A). (Courtesy of Thomas & Betts Corp.)

*Exception: Stainless steel shall not be required to have protective coatings.*

**(1) Protected from Corrosion Solely by Enamel.** Where protected from corrosion solely by enamel, ferrous metal raceways, cable trays, cablebus, auxiliary gutters, cable armor, boxes, cable sheathing, cabinets, metal elbows, couplings, nipples, fittings, supports, and support hardware

shall not be used outdoors or in wet locations as described in 300.6(D).

**(2) Organic Coatings on Boxes or Cabinets.** Where boxes or cabinets have an approved system of organic coatings and are marked “Raintight,” “Rainproof,” or “Outdoor Type,” they shall be permitted outdoors.

**(3) In Concrete or in Direct Contact with the Earth.** Ferrous metal raceways, cable armor, boxes, cable sheathing, cabinets, elbows, couplings, nipples, fittings, supports, and support hardware shall be permitted to be installed in concrete or in direct contact with the earth, or in areas subject to severe corrosive influences where made of material approved for the condition, or where provided with corrosion protection approved for the condition.

Where ferrous or nonferrous metal conduit has corrosion protection and is judged suitable for the condition, it may be installed in concrete, in contact with the earth, or in areas exposed to severe corrosive influence. Metal raceways installed in the earth can be coated with an asphalt compound, plastic sheath, or other equivalent protection to help prevent deterioration. Also, metal raceways are available with a bonded PVC coating. Special precautions are normally necessary for installing aluminum conduits in concrete to ensure adequate corrosion protection.

Galvanized rigid steel conduit and steel intermediate metal conduit do not generally require supplementary corrosion protection.

**(B) Aluminum Metal Equipment.** Aluminum raceways, cable trays, cablebus, auxiliary gutters, cable armor, boxes, cable sheathing, cabinets, elbows, couplings, nipples, fittings, supports, and support hardware embedded or encased in concrete or in direct contact with the earth shall be provided with supplementary corrosion protection.

**(C) Nonmetallic Equipment.** Nonmetallic raceways, cable trays, cablebus, auxiliary gutters, boxes, cables with a nonmetallic outer jacket and internal metal armor or jacket, cable sheathing, cabinets, elbows, couplings, nipples, fittings, supports, and support hardware shall be made of material approved for the condition and shall comply with (C)(1) and (C)(2) as applicable to the specific installation.

**(1) Exposed to Sunlight.** Where exposed to sunlight, the materials shall be listed as sunlight resistant or shall be identified as sunlight resistant.

**(2) Chemical Exposure.** Where subject to exposure to chemical solvents, vapors, splashing, or immersion, materials or coatings shall either be inherently resistant to chemi-

cals based on their listing or be identified for the specific chemical reagent.

**(D) Indoor Wet Locations.** In portions of dairy processing facilities, laundries, canneries, and other indoor wet locations, and in locations where walls are frequently washed or where there are surfaces of absorbent materials, such as damp paper or wood, the entire wiring system, where installed exposed, including all boxes, fittings, raceways, and cable used therewith, shall be mounted so that there is at least a 6-mm (¼-in.) airspace between it and the wall or supporting surface.

*Exception: Nonmetallic raceways, boxes, and fittings shall be permitted to be installed without the airspace on a concrete, masonry, tile, or similar surface.*

Informational Note: In general, areas where acids and alkali chemicals are handled and stored may present such corrosive conditions, particularly when wet or damp. Severe corrosive conditions may also be present in portions of meatpacking plants, tanneries, glue houses, and some stables; in installations immediately adjacent to a seashore and swimming pool areas; in areas where chemical deicers are used; and in storage cellars or rooms for hides, casings, fertilizer, salt, and bulk chemicals.

The exception to 300.6(D) coincides with 547.5(B), which permits nonmetallic boxes, fittings, conduit, and cables to be installed without the airspace in corrosive locations of agricultural buildings.

### 300.7 Raceways Exposed to Different Temperatures

**(A) Sealing.** Where portions of a raceway or sleeve are known to be subjected to different temperatures, and where condensation is known to be a problem, as in cold storage areas of buildings or where passing from the interior to the exterior of a building, the raceway or sleeve shall be filled with an approved material to prevent the circulation of warm air to a colder section of the raceway or sleeve. An explosionproof seal shall not be required for this purpose.

Section 300.7(A) addresses the problem of condensation forming in raceways or sleeves that are subjected to temperature differences as a result of air circulating through the raceway from a warmer to a colder section. For example, a raceway used to supply lighting or branch-circuit conductors within a walk-in refrigerator or freezer could have condensation within the raceway. Circulation of air can be prevented by sealing the raceway with a suitable pliable compound at a conduit body or junction box, usually installed in the raceway before it enters the colder section. Special sealing

fittings, such as those used in hazardous (classified) locations, are not necessary.

**(B) Expansion Fittings.** Raceways shall be provided with expansion fittings where necessary to compensate for thermal expansion and contraction.

Informational Note: Table 352.44 and Table 355.44 provide the expansion information for polyvinyl chloride (PVC) and for reinforced thermosetting resin conduit (RTRC), respectively. A nominal number for steel conduit can be determined by multiplying the expansion length in Table 352.44 by 0.20. The coefficient of expansion for steel electrical metallic tubing, intermediate metal conduit, and rigid conduit is  $1.170 \times 10^{-5}$  (0.0000117 mm per mm of conduit for each °C in temperature change) [0.650  $\times 10^{-5}$  (0.0000065 in. per inch of conduit for each °F in temperature change)].

A nominal number for aluminum conduit and aluminum electrical metallic tubing can be determined by multiplying the expansion length in Table 352.44 by 0.40. The coefficient of expansion for aluminum electrical metallic tubing and aluminum rigid metal conduit is  $2.34 \times 10^{-5}$  (0.0000234 mm per mm of conduit for each °C in temperature change) [ $1.30 \times 10^{-5}$  (0.000013) in. per inch of conduit for each °F in temperature change].

Raceway expansion and contraction can be a destructive force placed on a raceway system by a substantial increase (or substantial decrease) in temperature. Properly designed and installed expansion fittings allow raceways to expand and contract without damage to enclosures, raceways, and their conductors.

The informational note addresses expansion of aluminum rigid metal conduit and reinforced thermosetting resin conduit, Type RTRC. This informational note also provides a few simple relationships (or ratios) of linear expansion in length of PVC conduit to other types of conduit.

Knowing the *coefficient of expansion* of the conduit material (e.g., steel, aluminum, PVC, or fiberglass) and understanding that the *change in length* for a conduit is equal to the *coefficient of expansion* times the *change in temperature* times the *initial length* of the conduit is key to determining any temperature-related change in conduit length.

Calculation Example

An installation is completed on a day when the outside air temperature is 40°F. How much will a given 40 ft run of

conduit expand when the temperature reaches 95°F? The available conduit types are PVC, RTRC, RNC, IMC, and EMT. See Commentary Table 300.1, which provides a cross reference to the coefficient of expansion for various conduit and tubing types.

If a calculation indicated a linear expansion in length of 1¼ in. for PVC conduit, the steel conduit (or steel EMT) equivalent of expansion in length would be only ¼ in. If aluminum conduit were compared to a linear expansion in length of 1¼ in. for PVC conduit, the aluminum conduit equivalent expansion in length would be ½ in. Finally, for Type RTRC conduit, the final equivalent of expansion in length would be approximately ⅙ in.

300.8 Installation of Conductors with Other Systems

Raceways or cable trays containing electrical conductors shall not contain any pipe, tube, or equal for steam, water, air, gas, drainage, or any service other than electrical.

Section 300.8 specifically prohibits installation of an electrical conductor in a raceway or cable tray that includes a drain, water, oil, air, or similar pipe.

300.9 Raceways in Wet Locations Abovegrade

Where raceways are installed in wet locations abovegrade, the interior of these raceways shall be considered to be a wet location. Insulated conductors and cables installed in raceways in wet locations abovegrade shall comply with 310.10(C).

Section 300.9 applies to raceways installed in abovegrade wet locations. The insides of these raceways are definitively considered wet locations requiring conductors and cables that are listed for use in wet locations in accordance with 310.10(C).

300.10 Electrical Continuity of Metal Raceways and Enclosures

Metal raceways, cable armor, and other metal enclosures for conductors shall be metallically joined together into a con-

COMMENTARY TABLE 300.1 Expansion Coefficients for Conduit Types

Raceway Type	Reference Table	Expansion Coefficient	Expansion Length (Inches)
PVC	352.44	2.23	0.892
RTRC	355.44	0.99	0.396
RNC, IMC, or EMT	352.44 (Times 0.2)	0.446	0.178

tinuous electrical conductor and shall be connected to all boxes, fittings, and cabinets so as to provide effective electrical continuity. Unless specifically permitted elsewhere in this *Code*, raceways and cable assemblies shall be mechanically secured to boxes, fittings, cabinets, and other enclosures.

Sections 250.4(A) and (B) set forth in detail what must be accomplished by the grounding and bonding of metal parts of the electrical system. The metal parts must form an effective low-impedance path to ground in order to safely conduct any fault current and facilitate the operation of overcurrent devices protecting the enclosed circuit conductors.

*Exception No. 1: Short sections of raceways used to provide support or protection of cable assemblies from physical damage shall not be required to be made electrically continuous.*

*Exception No. 2: Equipment enclosures to be isolated, as permitted by 250.96(B), shall not be required to be metallically joined to the metal raceway.*

### 300.11 Securing and Supporting

**(A) Secured in Place.** Raceways, cable assemblies, boxes, cabinets, and fittings shall be securely fastened in place. Support wires that do not provide secure support shall not be permitted as the sole support. Support wires and associated fittings that provide secure support and that are installed in addition to the ceiling grid support wires shall be permitted as the sole support. Where independent support wires are used, they shall be secured at both ends. Cables and raceways shall not be supported by ceiling grids.

**(1) Fire-Rated Assemblies.** Wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling assembly shall not be secured to, or supported by, the ceiling assembly, including the ceiling support wires. An independent means of secure support shall be provided and shall be permitted to be attached to the assembly. Where independent support wires are used, they shall be distinguishable by color, tagging, or other effective means from those that are part of the fire-rated design.

*Exception: The ceiling support system shall be permitted to support wiring and equipment that have been tested as part of the fire-rated assembly.*

Wiring methods of any type and all luminaires are not allowed to be supported or secured to the support wires or T-bars of a fire-rated ceiling assembly unless the assembly has been tested and listed for that use. If support wires are se-

lected as the supporting means for the electrical system within the fire-rated ceiling cavity, they must be distinguishable from the ceiling support wires and must be secured at both ends.

Generally, the rule for supporting electrical equipment is that the equipment must be “securely fastened in place.” This phrase means not only that vertical support for the weight of the equipment must be provided but also that the equipment must be secured to prevent horizontal movement or sway. The intention is to prevent the loss of grounding continuity provided by the raceway that could result from horizontal movement.

Sections 300.11(A)(1) and (A)(2) are quite similar. Unless the exceptions apply, these sections clearly prohibit all types of wiring from being attached in any way to the support wires of a ceiling assembly. Unless ceiling grids are part of the building structure, they, too, are prohibited from furnishing support for cables and raceways. However, if wiring and equipment are located within the ceiling cavity and are rigidly supported independent of the ceiling, without the use of ceiling-type hanger wire, the requirements of this section are met. This section has been revised for the 2011 *Code*. Where independent support wires are used, they are required to be distinguishable by color, tagging, or other effective means. Often support wires for the ceiling have been indistinguishable from the wires installed for independent support of electrical equipment.

Refer to the appropriate wiring method article in Chapter 3 of the *Code* for cable and raceway supporting requirements. See Article 410, Part IV, for the proper support of luminaires; 314.23 for the support of outlet boxes; and 725.24, 760.24, and 770.24 for various low-voltage fire alarm and optical fiber cable supports. See Chapter 8 for communications cable supports.

*Informational Note: One method of determining fire rating is testing in accordance with NFPA 251-2006, Standard Methods of Tests of Fire Resistance of Building Construction and Materials.*

**(2) Non-Fire-Rated Assemblies.** Wiring located within the cavity of a non-fire-rated floor-ceiling or roof-ceiling assembly shall not be secured to, or supported by, the ceiling assembly, including the ceiling support wires. An independent means of secure support shall be provided and shall be permitted to be attached to the assembly. Where independent support wires are used, they shall be distinguishable by color, tagging, or other effective means.

*Exception: The ceiling support system shall be permitted to support branch-circuit wiring and associated equipment where installed in accordance with the ceiling system manufacturer's instructions.*

**(B) Raceways Used as Means of Support.** Raceways shall be used only as a means of support for other raceways, cables, or nonelectrical equipment under any of the following conditions:

- (1) Where the raceway or means of support is identified for the purpose
- (2) Where the raceway contains power supply conductors for electrically controlled equipment and is used to support Class 2 circuit conductors or cables that are solely for the purpose of connection to the equipment control circuits
- (3) Where the raceway is used to support boxes or conduit bodies in accordance with 314.23 or to support luminaires in accordance with 410.36(E)

As a general rule, 300.11(B) prohibits supporting cables by securing them to the exterior of a raceway. Electrical, telephone, and data cables wrapped around a raceway impede dissipation of heat from the raceway, thus affecting the temperature of the conductors contained in the raceway. The weight from large bundles of cables can also adversely affect the mechanical integrity of the raceway system. For the same reasons, this section also prohibits the use of a raceway as a means of support for nonelectrical equipment, such as suspended ceilings, water pipes, nonelectric signs, and the like.

However, 300.11(B)(2) does allow Class 2 conductors or cables to be supported by a raceway as long as the power supply conductors are inside the raceway or functionally associated with the attached Class 2 circuit conductors. For example, the thermostat conductors for heating or air-conditioner unit are permitted to be supported by the conduit supplying power to the unit. Exhibit 300.12 shows an example of this application with the Class 2 circuit cables for control of the heating equipment being secured to and supported by the electrical metallic tubing containing the power conductors for the equipment. These Class 2 circuits are functionally associated with the branch-circuit wiring method.

**(C) Cables Not Used as Means of Support.** Cable wiring methods shall not be used as a means of support for other cables, raceways, or nonelectrical equipment.

Section 300.11(C) prohibits cables from being used as a means of support for other cables, raceways, or nonelectrical equipment. Together, the requirements of 300.11(B) and (C) limit the practice of using one supported cable or raceway to support other raceways and cables.

### 300.12 Mechanical Continuity — Raceways and Cables

Metal or nonmetallic raceways, cable armors, and cable sheaths shall be continuous between cabinets, boxes, fittings, or other enclosures or outlets.

**EXHIBIT 300.12** Raceway used to support Class 2 thermostat cables specifically permitted by 300.11(B)(2).

*Exception No. 1: Short sections of raceways used to provide support or protection of cable assemblies from physical damage shall not be required to be mechanically continuous.*

*Exception No. 2: Raceways and cables installed into the bottom of open bottom equipment, such as switchboards, motor control centers, and floor or pad-mounted transformers, shall not be required to be mechanically secured to the equipment.*

Exception No. 2 to 300.12 specifically permits raceways and cables to enter switchgear from below without actually being attached to the underside of the switchboard, motor control center, or transformer where the equipment is constructed with an open-bottom feature. Where metal raceways or cables enter open-bottom-type equipment, electrical continuity between the wiring method and the equipment as required by 300.10 must be ensured.

### 300.13 Mechanical and Electrical Continuity — Conductors

**(A) General.** Conductors in raceways shall be continuous between outlets, boxes, devices, and so forth. There shall be no splice or tap within a raceway unless permitted by 300.15; 368.56(A); 376.56; 378.56; 384.56; 386.56; 388.56; or 390.7.

Section 300.13(A) prohibits splices or taps within raceways unless the raceways are equipped with hinged or removable covers. Busway conductors are exempt from this requirement. Splices and taps must be accessible according to 300.15.

**(B) Device Removal.** In multiwire branch circuits, the continuity of a grounded conductor shall not depend on device connections such as lampholders, receptacles, and so forth, where the removal of such devices would interrupt the continuity.

Grounded conductors (neutrals) of multiwire branch circuits supplying receptacles, lampholders, or other such devices are not permitted to depend on terminal connections for continuity between devices. For such installations (3- or 4-wire circuits), a splice is made and a jumper is connected to the terminal, unless the neutral is looped; that is, a receptacle or lampholder could be replaced without interrupting the continuity of energized downstream line-to-neutral loads (see the commentary following 300.14). Opening the neutral could cause unbalanced voltages, and a considerably higher voltage would be impressed on one part of a multiwire branch circuit, especially if the downstream line-to-neutral loads were appreciably unbalanced. Section 210.4(B) requires simultaneous disconnection of all ungrounded conductors for each multiwire branch circuit. See the associated commentary following 210.4(B). The requirement of 300.13(B) does not apply to individual 2-wire circuits or other circuits that do not contain a grounded (neutral) conductor.

### 300.14 Length of Free Conductors at Outlets, Junctions, and Switch Points

At least 150 mm (6 in.) of free conductor, measured from the point in the box where it emerges from its raceway or cable sheath, shall be left at each outlet, junction, and switch point for splices or the connection of luminaires or devices. Where the opening to an outlet, junction, or switch point is less than 200 mm (8 in.) in any dimension, each conductor shall be long enough to extend at least 75 mm (3 in.) outside the opening.

*Exception: Conductors that are not spliced or terminated at the outlet, junction, or switch point shall not be required to comply with 300.14.*

For a conductor that loops through an outlet box and that is intended for connection to a receptacle, switch, lampholder, or other such device, 300.14 specifies the length of slack (free conductor) required for the box size, as shown in Exhibit 300.13. The intent is to ensure enough slack for the terminal connections to be made easily. The exception excludes conductors running through a box, which should have sufficient slack to prevent physical damage from the insertion of devices or from the use of luminaire studs, hickeyes, or other luminaire supports within the box.

**EXHIBIT 300.13** Two different boxes with free conductor lengths according to 300.14.

### 300.15 Boxes, Conduit Bodies, or Fittings — Where Required

A box shall be installed at each outlet and switch point for concealed knob-and-tube wiring.

Fittings and connectors shall be used only with the specific wiring methods for which they are designed and listed.

Where the wiring method is conduit, tubing, Type AC cable, Type MC cable, Type MI cable, nonmetallic-sheathed cable, or other cables, a box or conduit body shall be installed at each conductor splice point, outlet point, switch point, junction point, termination point, or pull point, unless otherwise permitted in 300.15(A) through (L).

**(A) Wiring Methods with Interior Access.** A box or conduit body shall not be required for each splice, junction, switch, pull, termination, or outlet points in wiring methods with removable covers, such as wireways, multioutlet

assemblies, auxiliary gutters, and surface raceways. The covers shall be accessible after installation.

**(B) Equipment.** An integral junction box or wiring compartment as part of approved equipment shall be permitted in lieu of a box.

**(C) Protection.** A box or conduit body shall not be required where cables enter or exit from conduit or tubing that is used to provide cable support or protection against physical damage. A fitting shall be provided on the end(s) of the conduit or tubing to protect the cable from abrasion.

Section 300.15(C) permits conduit or tubing to be used as a sleeve that provides support and protection against physical damage for the wires or cables without terminating in a box. It also permits conduit or tubing to be used as physical protection for underground cables that exit from buildings or that are located outdoors on poles, without a box being required on the end of the conduit. A fitting to protect the wires or cables against physical damage is required on the ends of the conduit or tubing.

**(D) Type MI Cable.** A box or conduit body shall not be required where accessible fittings are used for straight-through splices in mineral-insulated metal-sheathed cable.

**(E) Integral Enclosure.** A wiring device with integral enclosure identified for the use, having brackets that securely fasten the device to walls or ceilings of conventional on-site frame construction, for use with nonmetallic-sheathed cable, shall be permitted in lieu of a box or conduit body.

Informational Note: See 334.30(C); 545.10; 550.15(I); 551.47(E), Exception No. 1; and 552.48(E), Exception No. 1.

Section 300.15(E) applies to a device with an integral enclosure (boxless device) such as the one shown in Exhibit 300.14.

**(F) Fitting.** A fitting identified for the use shall be permitted in lieu of a box or conduit body where conductors are not spliced or terminated within the fitting. The fitting shall be accessible after installation.

Where a cable system makes a transition to a raceway to provide mechanical protection against damage, 300.15(F) permits the use of a fitting instead of a box. For example, where nonmetallic-sheathed cable that runs overhead on floor joists and drops down on a masonry wall to supply a receptacle needs to be protected from physical damage, a

**EXHIBIT 300.14** A self-contained device (SCD) receptacle, one example of a boxless device permitted by 300.15(E). (Courtesy of Legrand/Pass & Seymour®)

short length of raceway is installed to the outlet device box. The cable is then inserted in the raceway and secured by a combination fitting that is fastened to the end of the raceway.

**(G) Direct-Buried Conductors.** As permitted in 300.5(E), a box or conduit body shall not be required for splices and taps in direct-buried conductors and cables.

**(H) Insulated Devices.** As permitted in 334.40(B), a box or conduit body shall not be required for insulated devices supplied by nonmetallic-sheathed cable.

**(I) Enclosures.** A box or conduit body shall not be required where a splice, switch, terminal, or pull point is in a cabinet or cutout box, in an enclosure for a switch or over-current device as permitted in 312.8, in a motor controller as permitted in 430.10(A), or in a motor control center.

**(J) Luminaires.** A box or conduit body shall not be required where a luminaire is used as a raceway as permitted in 410.64.

**(K) Embedded.** A box or conduit body shall not be required for splices where conductors are embedded as per-

mitted in 424.40, 424.41(D), 426.22(B), 426.24(A), and 427.19(A).

**(L) Manholes and Handhole Enclosures.** A box or conduit body shall not be required for conductors in manholes or handhole enclosures, except where connecting to electrical equipment. The installation shall comply with the provisions of Part V of Article 110 for manholes, and 314.30 for handhole enclosures.

### 300.16 Raceway or Cable to Open or Concealed Wiring

**(A) Box, Conduit Body, or Fitting.** A box, conduit body, or terminal fitting having a separately bushed hole for each conductor shall be used wherever a change is made from conduit, electrical metallic tubing, electrical nonmetallic tubing, nonmetallic-sheathed cable, Type AC cable, Type MC cable, or mineral-insulated, metal-sheathed cable and surface raceway wiring to open wiring or to concealed knob-and-tube wiring. A fitting used for this purpose shall contain no taps or splices and shall not be used at luminaire outlets. A conduit body used for this purpose shall contain no taps or splices, unless it complies with 314.16(C)(2).

**(B) Bushing.** A bushing shall be permitted in lieu of a box or terminal where the conductors emerge from a raceway and enter or terminate at equipment, such as open switchboards, unenclosed control equipment, or similar equipment. The bushing shall be of the insulating type for other than lead-sheathed conductors.

### 300.17 Number and Size of Conductors in Raceway

The number and size of conductors in any raceway shall not be more than will permit dissipation of the heat and ready installation or withdrawal of the conductors without damage to the conductors or to their insulation.

**Informational Note:** See the following sections of this *Code*: intermediate metal conduit, 342.22; rigid metal conduit, 344.22; flexible metal conduit, 348.22; liquidtight flexible metal conduit, 350.22; PVC conduit, 352.22; HDPE conduit, 353.22; RTRC, 355.22; liquidtight nonmetallic flexible conduit, 356.22; electrical metallic tubing, 358.22; flexible metallic tubing, 360.22; electrical nonmetallic tubing, 362.22; cellular concrete floor raceways, 372.11; cellular metal floor raceways, 374.5; metal wireways, 376.22; nonmetallic wireways, 378.22; surface metal raceways, 386.22; surface nonmetallic raceways, 388.22; underfloor raceways, 390.6; fixture wire, 402.7; theaters, 520.6; signs, 600.31(C); elevators, 620.33; audio signal processing, amplification, and reproduction equipment, 640.23(A) and 640.24; Class 1, Class 2, and Class 3 circuits, Article 725; fire alarm circuits, Article 760; and optical fiber cables and raceways, Article 770.

Listed wire-pulling compounds are available to assist in the process of pulling wires into raceways. As pointed out in 310.10(G) wire-pulling compounds should not be used if they have a harmful effect on either the conductor or the conductor insulation.

### 300.18 Raceway Installations

**(A) Complete Runs.** Raceways, other than busways or exposed raceways having hinged or removable covers, shall be installed complete between outlet, junction, or splicing points prior to the installation of conductors. Where required to facilitate the installation of utilization equipment, the raceway shall be permitted to be initially installed without a terminating connection at the equipment. Prewired raceway assemblies shall be permitted only where specifically permitted in this *Code* for the applicable wiring method.

*Exception:* Short sections of raceways used to contain conductors or cable assemblies for protection from physical damage shall not be required to be installed complete between outlet, junction, or splicing points.

One of the primary functions of a raceway is to provide physical protection for conductors. If raceways are incomplete at the time of conductor installation, a greater possibility exists for damage to the conductors.

Section 300.18(A) permits the installation of conductors in a raceway prior to the complete installation of the raceway, up to the point of utilization. The motor installation shown in Exhibit 300.15 is a typical example, where the motor will be supplied through liquidtight flexible metal

**EXHIBIT 300.15** An application of 300.18(A), which permits the conductors supplying a motor through liquidtight flexible metal conduit to be installed prior to the connection of the raceway to the motor terminal box.

conduit that terminates in the motor terminal box through a 90-degree angle connector. Wiring a luminaire whip prior to connecting a luminaire is also permitted by this section.

**(B) Welding.** Metal raceways shall not be supported, terminated, or connected by welding to the raceway unless specifically designed to be or otherwise specifically permitted to be in this *Code*.

300.19 Supporting Conductors in Vertical Raceways

**(A) Spacing Intervals — Maximum.** Conductors in vertical raceways shall be supported if the vertical rise exceeds the values in Table 300.19(A). One cable support shall be provided at the top of the vertical raceway or as close to the top as practical. Intermediate supports shall be provided as necessary to limit supported conductor lengths to not greater than those values specified in Table 300.19(A).

Conductors in long vertical runs must be supported if the vertical rise exceeds the values in Table 300.19(A). This requirement prevents the weight of the conductors from damaging the insulation where they leave the conduit and prevents the conductors from being pulled out of the terminals. Support bushings or cleats such as those shown in Exhibits 300.16 and 300.17 may be used, in addition to many other types of grips manufactured for this purpose.

Application Example

A vertical raceway contains 1/0 AWG copper conductors. Using Table 300.19(A), if the vertical run is not greater than 100 ft, 300.19(A) requires one cable support near the top of the run. For longer vertical runs, 300.19(A) requires intermediate supports to limit the supported length to the table values. If the vertical run is less than 100 ft, cable supports are not required.

**EXHIBIT 300.16** A support bushing, located at the top of a vertical conduit at a cabinet or pull box, used to prevent the weight of the conductors from damaging insulation or placing strain on termination points.

*Exception:* Steel wire armor cable shall be supported at the top of the riser with a cable support that clamps the steel wire armor. A safety device shall be permitted at the lower end of the riser to hold the cable in the event there is slippage of the cable in the wire-armored cable support. Addi-

TABLE 300.19(A) Spacings for Conductor Supports

		Conductors			
Conductor Size	Support of Conductors in Vertical Raceways	Aluminum or Copper-Clad Aluminum		Copper	
		m	ft	m	ft
18 AWG through 8 AWG	Not greater than	30	100	30	100
6 AWG through 1/0 AWG	Not greater than	60	200	30	100
2/0 AWG through 4/0 AWG	Not greater than	55	180	25	80
Over 4/0 AWG through 350 kcmil	Not greater than	41	135	18	60
Over 350 kcmil through 500 kcmil	Not greater than	36	120	15	50
Over 500 kcmil through 750 kcmil	Not greater than	28	95	12	40
Over 750 kcmil	Not greater than	26	85	11	35

**EXHIBIT 300.17** Support cleats used to prevent the weight of vertical conductors from damaging insulation or placing strain on termination points.

tional wedge-type supports shall be permitted to relieve the strain on the equipment terminals caused by expansion of the cable under load.

**(B) Fire-Rated Cables and Conductors.** Support methods and spacing intervals for fire-rated cables and conductors shall comply with any restrictions provided in the listing of the electrical circuit protective system used and in no case shall exceed the values in Table 300.19(A).

Electrical circuit protective systems using fire-rated cable assemblies, generally require more frequent and robust support systems. For example, one manufacturer of Type MI fire-rated cable requires that vertical runs of a two-hour fire-rated assembly be supported every 4 ft, varying substantially from the support requirements of Table 300.19(A).

**(C) Support Methods.** One of the following methods of support shall be used:

- (1) By clamping devices constructed of or employing insulating wedges inserted in the ends of the raceways. Where clamping of insulation does not adequately support the cable, the conductor also shall be clamped.
- (2) By inserting boxes at the required intervals in which insulating supports are installed and secured in a satisfactory manner to withstand the weight of the conductors attached thereto, the boxes being provided with covers.
- (3) In junction boxes, by deflecting the cables not less than 90 degrees and carrying them horizontally to a distance not less than twice the diameter of the cable, the cables

being carried on two or more insulating supports and additionally secured thereto by tie wires if desired. Where this method is used, cables shall be supported at intervals not greater than 20 percent of those mentioned in the preceding tabulation.

- (4) By a method of equal effectiveness.

### 300.20 Induced Currents in Ferrous Metal Enclosures or Ferrous Metal Raceways

**(A) Conductors Grouped Together.** Where conductors carrying alternating current are installed in ferrous metal enclosures or ferrous metal raceways, they shall be arranged so as to avoid heating the surrounding ferrous metal by induction. To accomplish this, all phase conductors and, where used, the grounded conductor and all equipment grounding conductors shall be grouped together.

Nonferrous metals are defined as those with little or no iron in their composition. Some of the more common nonferrous (nonmagnetic) metals include aluminum, brass, bronze, copper, lead, tin, and zinc. Section 300.20(A) addresses the problem of induction from ac conductors into ferrous (magnetic) metal enclosures and ferrous raceways. Induction into raceways and enclosures can lead to overheating. It is also a shock hazard.

*Exception No. 1: Equipment grounding conductors for certain existing installations shall be permitted to be installed separate from their associated circuit conductors where run in accordance with the provisions of 250.130(C).*

*Exception No. 2: A single conductor shall be permitted to be installed in a ferromagnetic enclosure and used for skin-effect heating in accordance with the provisions of 426.42 and 427.47.*

**(B) Individual Conductors.** Where a single conductor carrying alternating current passes through metal with magnetic properties, the inductive effect shall be minimized by (1) cutting slots in the metal between the individual holes through which the individual conductors pass or (2) passing all the conductors in the circuit through an insulating wall sufficiently large for all of the conductors of the circuit.

*Exception: In the case of circuits supplying vacuum or electric-discharge lighting systems or signs or X-ray apparatus, the currents carried by the conductors are so small that the inductive heating effect can be ignored where these conductors are placed in metal enclosures or pass through metal.*

**Informational Note:** Because aluminum is not a magnetic metal, there will be no heating due to hysteresis; however, induced currents will be present. They will not be of suffi-

cient magnitude to require grouping of conductors or special treatment in passing conductors through aluminum wall sections.

### 300.21 Spread of Fire or Products of Combustion

Electrical installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around electrical penetrations **into or** through fire-resistant-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

**Informational Note:** Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made. Building codes also contain restrictions on membrane penetrations on opposite sides of a fire-resistance-rated wall assembly. An example is the 600-mm (24-in.) minimum horizontal separation that usually applies between boxes installed on opposite sides of the wall. Assistance in complying with 300.21 can be found in building codes, fire resistance directories, and product listings.

Section 300.21 requires cables, cable trays, and raceways be installed through fire-rated walls, floors, and ceiling assemblies using an approved firestop method so that they do not contribute to the spread of fire or the products of combustion. In the *UL Guide Information for Electrical Equipment — The White Book-2010*, Category XHEZ covers through-penetration firestop systems and Category XHLI covers fire-stop devices. These two category sections provide valuable information concerning application, installation, and use of firestop systems and firestop devices. A firestop system, the seals for which are shown in Exhibit 300.18, meets the requirements of 300.21.

Using the proper protection techniques is crucial in limiting or stopping products of combustion such as flame, excessive temperature, and smoke from passing through fire-rated construction. The structural integrity of the floor or wall assembly needs to be evaluated when providing openings for the penetrating items.

First, the rating of the building assembly being penetrated by electrical cables or conduits must be determined. This information is available from construction documents or building codes. Once the fire-resistance rating of the penetrated wall or floor or ceiling-floor assembly has been determined, the properties and types of electrical penetration required, such as metal or nonmetallic cable(s) or conduit(s) or even cable trays, must be identified. Next, the method of fire stopping must be selected. Remember, according to 300.21, the selected method must first be approved and satisfactory to the authority having jurisdiction. The building

**EXHIBIT 300.18** Fire seals used in a through-penetration fire-stop system to maintain the fire resistance rating of the wall, as required by 300.21. (Courtesy of O-Z/Gedney, a division of EGS Electrical Group)

codes generally require that a firestop system or device be tested in accordance with ASTM E 814-2006, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*, or ANSI/UL 1479-2006, *Fire Tests of Through-Penetration Firestops*. But, as an alternative to these tested systems or devices, NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls* (as well as some building codes), contains a statement somewhat similar to the following:

Where concrete, grout, or mortar has been used to fill the annular spaces around . . . steel conduit or tubing that penetrates one or more concrete or masonry walls, the nominal diameter of each penetrating item shall not exceed 6 in., the opening size shall not exceed 144 in.<sup>2</sup> and the thickness of the concrete, grout, or mortar shall be the full thickness of the assembly.

### 300.22 Wiring in Ducts Not Used for Air Handling, Fabricated Ducts for Environmental Air, and Other Spaces for Environmental Air (Plenums)

The provisions of this section shall apply to the installation and uses of electrical wiring and equipment in ducts **used for dust, loose stock, or vapor removal; ducts specifically fabricated for environmental air; and other spaces used for environmental air (plenums).**

**Informational Note:** See Article 424, Part VI, for duct heaters.

This section was revised for the 2011 *Code* to clarify the use of the terms *duct*, *plenum*, and *other spaces used for environmental air*. Other codes and standards refer to all spaces

that move air as *plenums*, including spaces that the *NEC* identifies as *other spaces*. Some of the terms used to describe this space include *plenum*, *ceiling cavity plenum*, and *raised floor plenum*. Products are often required to be marked as “suitable for use in other spaces for environmental air” or equivalent language to comply with requirements in the *NEC*.

The term *plenum* was removed from 300.22(B) to clarify that the section addresses ducts and spaces being used solely for the movement of environmental air. The term *other spaces used for environmental air* was revised to make it clear that it applies to structures that were not fabricated specifically to handle environmental air as the primary purpose, but handle the air nonetheless. Such spaces are plenums.

**(A) Ducts for Dust, Loose Stock, or Vapor Removal.** No wiring systems of any type shall be installed in ducts used to transport dust, loose stock, or flammable vapors. No wiring system of any type shall be installed in any duct, or shaft containing only such ducts, used for vapor removal or for ventilation of commercial-type cooking equipment.

**(B) Ducts Specifically Fabricated for Environmental Air.** Only wiring methods consisting of Type MI cable, Type MC cable employing a smooth or corrugated impervious metal sheath without an overall nonmetallic covering, electrical metallic tubing, flexible metallic tubing, intermediate metal conduit, or rigid metal conduit without an overall nonmetallic covering shall be installed in **ducts specifically** fabricated to transport environmental air. Flexible metal conduit shall be permitted, in lengths not to exceed 1.2 m (4 ft), to connect physically adjustable equipment and devices permitted to be in these **fabricated ducts**. The connectors used with flexible metal conduit shall effectively close any openings in the connection. Equipment and devices shall be permitted within such **ducts only** if necessary for the direct action upon, or sensing of, the contained air. Where equipment or devices are installed and illumination is necessary to facilitate maintenance and repair, enclosed gasketed-type luminaires shall be permitted.

Section 300.22 limits the use of materials that would contribute smoke and products of combustion during a fire in an area that handles environmental air. Section 300.22(B) provides for an effective barrier against the spread of products of combustion through ducts specifically fabricated for environmental air.

Section 300.22(B) applies to sheet metal ducts and other ducts specifically constructed to transport environmental air. Because equipment and devices such as luminaires and motors are not normally permitted in ducts or plenums,

the wiring methods in 300.22(B) differ from those permitted in 300.22(C).

**(C) Other Spaces Used for Environmental Air (Plenums).** This section shall apply to spaces not specifically fabricated for environmental air-handling purposes but used for air-handling purposes as a plenum. This section shall not apply to habitable rooms or areas of buildings, the prime purpose of which is not air handling.

Informational Note No. 1: The space over a hung ceiling used for environmental air-handling purposes is an example of the type of other space to which this section applies.

Informational Note No. 2: The phrase “Other Spaces Used for Environmental Air (Plenum)” as used in this section correlates with the use of the term “plenum” in NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, and other mechanical codes where the plenum is used for return air purposes, as well as some other air-handling spaces.

Section 300.22(C) applies to other spaces or plenums — such as the space or cavity between a structural floor or roof and a suspended (hung) ceiling — that are used to transport environmental air and that are not specifically manufactured as ducts. Many spaces above suspended ceilings are intended to transport return air. Some spaces are also used for supply air, but they are far less common than those used for return air. This section does not apply to habitable rooms and other areas whose prime purpose is other than air handling. Such an area is shown in Exhibit 300.19. If the prime

**EXHIBIT 300.19** An application of 300.22(C). Ordinary wiring methods are permitted in habitable areas that are not used primarily for air handling. Only wiring methods described in 300.22(C)(1) are permitted in rooms or spaces that are primarily used for air handling.

purpose of the room or space is air handling as depicted in Exhibit 300.19, the restrictions in 300.22(C) apply, whether or not electrical equipment is located in the room. This section was revised and Informational Note No. 2 was added to correlate the term *other spaces used with environmental air* with the term *plenum* as used in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

*Exception: This section shall not apply to the joist or stud spaces of dwelling units where the wiring passes through such spaces perpendicular to the long dimension of such spaces.*

The exception to 300.22(C) permits cable to pass through joist or stud spaces of a dwelling unit, where the joist space is used as a return for a forced-air central heating or air-conditioning system. As shown in Exhibit 300.20, the joist space is covered with appropriate material, and the cable passes through the space perpendicular to the vertical run. The exception does not permit equipment such as junction boxes or device enclosures within this space unless the wiring method employed and enclosure type used meet the requirements of both 300.22(C)(1) and (C)(2).

**EXHIBIT 300.20** A cable passing through joist spaces of a dwelling unit, as permitted by 300.22(C), Exception.

**(1) Wiring Methods.** The wiring methods for such other space shall be limited to totally enclosed, nonventilated, insulated busway having no provisions for plug-in connections, Type MI cable, Type MC cable without an overall nonmetallic covering, Type AC cable, or other factory-assembled multiconductor control or power cable that is specifically listed for use within an air-handling space, or listed prefabricated cable assemblies of metallic manufactured wiring systems without nonmetallic sheath. Other

types of cables, conductors, and raceways shall be permitted to be installed in electrical metallic tubing, flexible metallic tubing, intermediate metal conduit, rigid metal conduit without an overall nonmetallic covering, flexible metal conduit, or, where accessible, surface metal raceway or metal wireway with metal covers.

**(2) Cable Tray Systems.** The provisions in (a) or (b) shall apply to the use of metallic cable tray systems in other spaces used for environmental air (plenums), where accessible, as follows:

This section was added for the 2011 *Code* to clarify requirements for cable tray installation. Cable trays are a support system. They are permitted to support any wiring permitted to be installed in plenums per 300.22(C)(1). Solid bottom cable trays with solid metal covers and solid sides can support any system allowed in 392.10 because they would completely enclose the wiring method.

(a) **Metal Cable Tray Systems.** Metal cable tray systems shall be permitted to support the wiring methods in 300.22(C)(1).

(b) **Solid Side and Bottom Metal Cable Tray Systems.** Solid side and bottom metal cable tray systems with solid metal covers shall be permitted to enclose wiring methods and cables, not already covered in 300.22(C)(1), in accordance with 392.10(A) and (B).

**(3) Equipment.** Electrical equipment with a metal enclosure, or electrical equipment with a nonmetallic enclosure listed for use within an air-handling space and having adequate fire-resistant and low-smoke-producing characteristics, and associated wiring material suitable for the ambient temperature shall be permitted to be installed in such other space unless prohibited elsewhere in this *Code*.

**Informational Note:** One method of defining adequate fire-resistant and low-smoke producing characteristics for electrical equipment with a nonmetallic enclosure is in ANSI/UL 2043-2008, *Fire Test for Heat and Visible Smoke Release for Discrete Products and Their Accessories Installed in Air-Handling Spaces*.

*Exception: Integral fan systems shall be permitted where specifically identified for use within an air-handling space.*

Electrical equipment with metal enclosures is allowed within spaces used for environmental air. Nonmetallic enclosures are only permitted if they are specifically listed for use within air-handling spaces.

**(D) Information Technology Equipment.** Electrical wiring in air-handling areas beneath raised floors for information technology equipment shall be permitted in accordance with Article 645.

It is not intended that the requirements of 300.22(B) or (C) apply to air-handling areas beneath raised floors in information technology equipment rooms that meet the requirements specified in Article 645. See Article 645, Information Technology Equipment, for more information.

### 300.23 Panels Designed to Allow Access

Cables, raceways, and equipment installed behind panels designed to allow access, including suspended ceiling panels, shall be arranged and secured so as to allow the removal of panels and access to the equipment.

## II. Requirements for over 600 Volts, Nominal

### 300.31 Covers Required

Suitable covers shall be installed on all boxes, fittings, and similar enclosures to prevent accidental contact with energized parts or physical damage to parts or insulation.

### 300.32 Conductors of Different Systems

See 300.3(C)(2).

### 300.34 Conductor Bending Radius

The conductor shall not be bent to a radius less than 8 times the overall diameter for nonshielded conductors or 12 times the overall diameter for shielded or lead-covered conductors during or after installation. For multiconductor or multiplexed single-conductor cables having individually shielded conductors, the minimum bending radius is 12 times the diameter of the individually shielded conductors or 7 times the overall diameter, whichever is greater.

### 300.35 Protection Against Induction Heating

Metallic raceways and associated conductors shall be arranged so as to avoid heating of the raceway in accordance with the applicable provisions of 300.20.

### 300.37 Aboveground Wiring Methods

Aboveground conductors shall be installed in rigid metal conduit, in intermediate metal conduit, in electrical metallic tubing, in RTRC and PVC conduit, in cable trays, in auxiliary gutters, as busways, as cablebus, in other identified raceways, or as exposed runs of metal-clad cable suitable for the use and purpose. In locations accessible to qualified per-

sons only, exposed runs of Type MV cables, bare conductors, and bare busbars shall also be permitted. Busbars shall be permitted to be either copper or aluminum.

In transformer vaults, switch rooms, and similar areas restricted to qualified personnel, 300.37 permits any suitable wiring method to be used. Exposed wiring using bare or insulated conductors on insulators is commonly employed, as is rigid metal conduit and rigid PVC and RTRC conduit.

### 300.39 Braid-Covered Insulated Conductors — Exposed Installation

Exposed runs of braid-covered insulated conductors shall have a flame-retardant braid. If the conductors used do not have this protection, a flame-retardant saturant shall be applied to the braid covering after installation. This treated braid covering shall be stripped back a safe distance at conductor terminals, according to the operating voltage. Where practicable, this distance shall not be less than 25 mm (1 in.) for each kilovolt of the conductor-to-ground voltage of the circuit.

### 300.40 Insulation Shielding

Metallic and semiconducting insulation shielding components of shielded cables shall be removed for a distance dependent on the circuit voltage and insulation. Stress reduction means shall be provided at all terminations of factory-applied shielding.

Metallic shielding components such as tapes, wires, or braids, or combinations thereof, shall be connected to a grounding conductor, grounding busbar, or a grounding electrode.

### 300.42 Moisture or Mechanical Protection for Metal-Sheathed Cables

Where cable conductors emerge from a metal sheath and where protection against moisture or physical damage is necessary, the insulation of the conductors shall be protected by a cable sheath terminating device.

### 300.50 Underground Installations

**(A) General.** Underground conductors shall be identified for the voltage and conditions under which they are installed. Direct-burial cables shall comply with the provisions of 310.10(F). Underground cables shall be installed in accordance with 300.50(A)(1) or (A)(2), and the installation shall meet the depth requirements of Table 300.50.

Prior to backfilling a ditch or trench, a warning ribbon must be placed near underground direct-buried conductors over

TABLE 300.50 Minimum Cover<sup>a</sup> Requirements

Circuit Voltage	General Conditions (not otherwise specified)						Special Conditions (use if applicable)					
	Column 1		Column 2		Column 3		Column 4		Column 5		Column 6	
	Direct-Buried Cables <sup>d</sup>		RTRC, PVC, and HDPE Conduit <sup>b</sup>		Rigid Metal Conduit and Intermediate Metal Conduit		Raceways Under Buildings or Exterior Concrete Slabs, 100 mm (4 in.) Minimum Thickness <sup>c</sup>		Cables in Airport Runways or Adjacent Areas Where Trespass Is Prohibited		Areas Subject to Vehicular Traffic, Such as Thoroughfares and Commercial Parking Areas	
	mm	in.	mm	in.	mm	in.	mm	in.	mm	in.	mm	in.
Over 600 V through 22 kV	750	30	450	18	150	6	100	4	450	18	600	24
Over 22 kV through 40 kV	900	36	600	24	150	6	100	4	450	18	600	24
Over 40 kV	1000	42	750	30	150	6	100	4	450	18	600	24

## General Notes:

1. Lesser depths shall be permitted where cables and conductors rise for terminations or splices or where access is otherwise required.
2. Where solid rock prevents compliance with the cover depths specified in this table, the wiring shall be installed in a metal or nonmetallic raceway permitted for direct burial. The raceways shall be covered by a minimum of 50 mm (2 in.) of concrete extending down to rock.
3. In industrial establishments, where conditions of maintenance and supervision ensure that qualified persons will service the installation, the minimum cover requirements, for other than rigid metal conduit and intermediate metal conduit, shall be permitted to be reduced 150 mm (6 in.) for each 50 mm (2 in.) of concrete or equivalent placed entirely within the trench over the underground installation.

## Specific Footnotes:

<sup>a</sup> Cover is defined as the shortest distance in millimeters (inches) measured between a point on the top surface of any direct-buried conductor, cable, conduit, or other raceway and the top surface of finished grade, concrete, or similar cover.

<sup>b</sup> Listed by a qualified testing agency as suitable for direct burial without encasement. All other nonmetallic systems shall require 50 mm (2 in.) of concrete or equivalent above conduit in addition to the table depth.

<sup>c</sup> The slab shall extend a minimum of 150 mm (6 in.) beyond the underground installation, and a warning ribbon or other effective means suitable for the conditions shall be placed above the underground installation.

<sup>d</sup> Underground direct-buried cables that are not encased or protected by concrete and are buried 750 mm (30 in.) or more below grade shall have their location identified by a warning ribbon that is placed in the trench at least 300 mm (12 in.) above the cables.

600 volts, nominal, that are not encased in concrete. This requirement is intended to reduce the risk of an accident, electrocution, or arc-flash incident during excavation.

**(1) Shielded Cables and Nonshielded Cables in Metal-Sheathed Cable Assemblies.** Underground cables, including nonshielded, Type MC and moisture-impervious metal sheath cables, shall have those sheaths grounded through an effective grounding path meeting the requirements of 250.4(A)(5) or (B)(4). They shall be direct buried or installed in raceways identified for the use.

**(2) Other Nonshielded Cables.** Other nonshielded cables not covered in 300.50(A)(1) shall be installed in rigid metal

conduit, intermediate metal conduit, or rigid nonmetallic conduit encased in not less than 75 mm (3 in.) of concrete.

**(B) Wet Locations.** The interior of enclosures or raceways installed underground shall be considered to be a wet location. Insulated conductors and cables installed in these enclosures or raceways in underground installations shall be listed for use in wet locations and shall comply with 310.10(C). Any connections or splices in an underground installation shall be approved for wet locations.

This section has been revised for the 2011 *Code* to correlate with 300.5(B). Section 300.50(B) requires that the inside of

all raceways and enclosures installed underground be classified as a wet location. Conductors installed in such underground locations must be listed for use in wet locations and comply with 310.10(C).

**(C) Protection from Damage.** Conductors emerging from the ground shall be enclosed in listed raceways. Raceways installed on poles shall be of rigid metal conduit, intermediate metal conduit, **RTRC-XW**, Schedule 80 PVC conduit, or equivalent, extending from the minimum cover depth specified in Table 300.50 to a point 2.5 m (8 ft) above finished grade. Conductors entering a building shall be protected by an approved enclosure or raceway from the minimum cover depth to the point of entrance. Where direct-buried conductors, raceways, or cables are subject to movement by settlement or frost, they shall be installed to prevent damage to the enclosed conductors or to the equipment connected to the raceways. Metallic enclosures shall be grounded.

**(D) Splices.** Direct burial cables shall be permitted to be spliced or tapped without the use of splice boxes, provided they are installed using materials suitable for the application. The taps and splices shall be watertight and protected from mechanical damage. Where cables are shielded, the shielding shall be continuous across the splice or tap.

*Exception: At splices of an engineered cabling system, metallic shields of direct-buried single-conductor cables with maintained spacing between phases shall be permitted to be interrupted and overlapped. Where shields are interrupted and overlapped, each shield section shall be grounded at one point.*

**(E) Backfill.** Backfill containing large rocks, paving materials, cinders, large or sharply angular substances, or corrosive materials shall not be placed in an excavation where materials can damage or contribute to the corrosion of raceways, cables, or other substructures or where it may prevent adequate compaction of fill.

Protection in the form of granular or selected material or suitable sleeves shall be provided to prevent physical damage to the raceway or cable.

**(F) Raceway Seal.** Where a raceway enters from an underground system, the end within the building shall be sealed with an identified compound so as to prevent the entrance of moisture or gases, or it shall be so arranged to prevent moisture from contacting live parts.

## I. General

### 310.1 Scope

This article covers general requirements for conductors and their type designations, insulations, markings, mechanical

strengths, ampacity ratings, and uses. These requirements do not apply to conductors that form an integral part of equipment, such as motors, motor controllers, and similar equipment, or to conductors specifically provided for elsewhere in this *Code*.

Informational Note: For flexible cords and cables, see Article 400. For fixture wires, see Article 402.

## 310.2 Definitions

**Electrical Ducts.** Electrical conduits, or other raceways round in cross section, that are suitable for use underground or embedded in concrete.

**Thermal Resistivity.** As used in this *Code*, the heat transfer capability through a substance by conduction. It is the reciprocal of thermal conductivity and is designated Rho and expressed in the units °C-cm/W.

## II. Installation

### 310.10 Uses Permitted

The conductors described in 310.104 shall be permitted for use in any of the wiring methods covered in Chapter 3 and as specified in their respective tables or as permitted elsewhere in this *Code*.

Informational Note: Thermoplastic insulation may stiffen at temperatures lower than  $-10^{\circ}\text{C}$  ( $+14^{\circ}\text{F}$ ). Thermoplastic insulation may also be deformed at normal temperatures where subjected to pressure, such as at points of support. Thermoplastic insulation, where used on dc circuits in wet locations, may result in electroendosmosis between the conductor and insulation.

**(A) Dry Locations.** Insulated conductors and cables used in dry locations shall be any of the types identified in this *Code*.

**(B) Dry and Damp Locations.** Insulated conductors and cables used in dry and damp locations shall be Types FEP, FEPB, MTW, PFA, RHH, RHW, RHW-2, SA, THHN, THW, THW-2, THHW, THWN, THWN-2, TW, XHH, XHHW, XHHW-2, Z, or ZW.

**(C) Wet Locations.** Insulated conductors and cables used in wet locations shall comply with one of the following:

- (1) Be moisture-impervious metal-sheathed
- (2) Be types MTW, RHW, RHW-2, TW, THW, THW-2, THHW, THWN, THWN-2, XHHW, XHHW-2, ZW
- (3) Be of a type listed for use in wet locations

**(D) Locations Exposed to Direct Sunlight.** Insulated conductors or cables used where exposed to direct rays of the sun shall comply with (D)(1) or (D)(2):

- (1) Conductors and cables shall be listed, or listed and marked, as being sunlight resistant
- (2) Conductors and cables shall be covered with insulating material, such as tape or sleeving, that is listed, or listed and marked, as being sunlight resistant

**(E) Shielding.** Non-shielded, ozone-resistant insulated conductors with a maximum phase-to-phase voltage of 5000 volts shall be permitted in Type MC cables in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation. For other establishments, solid dielectric insulated conductors operated above 2000 volts in permanent installations shall have ozone-resistant insulation and shall be shielded. All metallic insulation shields shall be connected to a grounding electrode conductor, a grounding bus-bar, an equipment grounding conductor, or a grounding electrode.

This section has been revised for the 2011 *Code* to permit the use of nonshielded, ozone-resistant insulated conductors in Type MC cable with a maximum phase-to-phase voltage of 5 kV. The construction of metal-armored cable provides enhanced reliability because the conductors have a concentric lay-orientation and their insulation is protected from damage during installation. The requirements for insulation performance and the limitation to industrial establishments with qualified personnel ensure a safe installation.

Nonshielded conductors within metal raceways do not provide the same level of reliability. The inconsistencies of a conductors-into-conduit installation do not ensure a lack of insulation damage and do not assure a concentric lay-orientation of the cables.

Solid dielectric insulated conductors that are permanently installed and that operate at greater than 2000 volts are required to have ozone-resistant insulation and must be shielded with a grounded metallic shield. Shielding is accomplished by applying a metal tape or nonmetallic semi-conducting tape around the conductor surface to prevent corona from forming and to reduce high-voltage stresses.

Corona is a faint glow adjacent to the surface of the electrical conductor at high voltage. If high-voltage stresses and a charging current are flowing between the conductor and ground (usually due to moisture), the surrounding atmosphere is ionized, and ozone — generated by an electric discharge in ordinary oxygen or air — is formed and will attack the conductor jacket and insulation and may eventually break them down. The shield is at ground potential; therefore, no voltage above ground is present on the jacket outside the shield, thus preventing a discharge from the jacket and the subsequent formation of ozone.

Exhibits 310.1 and 310.2 illustrate shielded cable installations: a three-conductor cable of the shielded type, a

**EXHIBIT 310.1** A three-conductor cable of the shielded type in accordance with 310.10(E).

**EXHIBIT 310.2** (Left) A one-piece, preformed stress-relief cone for indoor cable terminations of up to 35 kV phase-to-phase according to 310.10(E). (Right) A stress cone on a single-conductor shielded cable terminating inside a pothead according to 310.10(E).

stress-relief cone for an indoor cable terminator, and a stress cone on a single-conductor shielded cable terminating inside a pothead. In Exhibit 310.2 (right), a clamping ring provides a grounding connection between the copper shielding tape and the shield to the metallic base of the pothead.

**Informational Note:** The primary purposes of shielding are to confine the voltage stresses to the insulation, dissipate insulation leakage current, drain off the capacitive charging

current, and carry ground-fault current to facilitate operation of ground-fault protective devices in the event of an electrical cable fault.

*Exception No. 1: Nonshielded insulated conductors listed by a qualified testing laboratory shall be permitted for use up to 2400 volts under the following conditions:*

- (a) *Conductors shall have insulation resistant to electric discharge and surface tracking, or the insulated conductor(s) shall be covered with a material resistant to ozone, electric discharge, and surface tracking.*
- (b) *Where used in wet locations, the insulated conductor(s) shall have an overall nonmetallic jacket or a continuous metallic sheath.*
- (c) *Insulation and jacket thicknesses shall be in accordance with Table 310.104(D).*

*Exception No. 2: Nonshielded insulated conductors listed by a qualified testing laboratory shall be permitted for use up to 5000 volts to replace existing nonshielded conductors, on existing equipment in industrial establishments only, under the following conditions:*

- (a) *Where the condition of maintenance and supervision ensures that only qualified personnel install and service the installation.*
- (b) *Conductors shall have insulation resistant to electric discharge and surface tracking, or the insulated conductor(s) shall be covered with a material resistant to ozone, electric discharge, and surface tracking.*
- (c) *Where used in wet locations, the insulated conductor(s) shall have an overall nonmetallic jacket or a continuous metallic sheath.*
- (d) *Insulation and jacket thicknesses shall be in accordance with Table 310.13(D).*

Informational Note: Relocation or replacement of equipment may not comply with the term *existing* as related to this exception.

Exception No. 1 to 310.10(E) limits the omission of shielding up to the 2.4-kV level only, which correlates with 310.10(F) for direct-burial conductors. Exception No. 2 is new for the 2011 *Code*. It recognizes that nonshielded cables with insulation ratings of up to 5000 volts were previously permitted. Where cable in an existing installation requires replacement, it may be preferable to replace a nonshielded cable with another nonshielded cable where existing raceways and termination enclosures do not provide adequate space for shielded conductors and their associated terminations.

Federal Aviation Administration Advisory Circulars for airfield lighting cable permit certain circuits up to 5 kV to be unshielded. See 310.10(F), Exception No. 2 for permitted uses of nonshielded cable in airfield lighting.

Specialized training and close adherence to manufacturers' instructions are absolutely essential for high-voltage cable installations.

*Exception No. 3: Where permitted in 310.10(F), Exception No. 2.*

**(F) Direct-Burial Conductors.** Conductors used for direct-burial applications shall be of a type identified for such use.

*Exception No. 1: Nonshielded multiconductor cables rated 2001–2400 volts shall be permitted if the cable has an overall metallic sheath or armor.*

The metallic shield, sheath, or armor shall be connected to a grounding electrode conductor, grounding busbar, or a grounding electrode.

*Exception No. 2: Airfield lighting cable used in series circuits that are rated up to 5000 volts and are powered by regulators shall be permitted to be nonshielded.*

Informational Note to Exception No. 2: Federal Aviation Administration (FAA) Advisory Circulars (ACs) provide additional practices and methods for airport lighting.

Informational Note No. 1: See 300.5 for installation requirements for conductors rated 600 volts or less.

Informational Note No. 2: See 300.50 for installation requirements for conductors rated over 600 volts.

Exception No. 1 to 310.10(F) limits the omission of shielding up to the 2.4-kV level only for direct-burial conductors. In coordination with Federal Aviation Administration Advisory Circulars for airfield lighting cable, Exception No. 2 permits certain circuits up to 5 kV to be unshielded as well. See 310.10(F), Exception No. 2 and the associated informational note for specific provisions and original source material.

**(G) Corrosive Conditions.** Conductors exposed to oils, greases, vapors, gases, fumes, liquids, or other substances having a deleterious effect on the conductor or insulation shall be of a type suitable for the application.

Nylon-jacketed conductors, such as Type THWN, for example, are suitable for use where exposed to gasoline.

The *UL Guide Information for Electrical Equipment — The White Book-2010* states in the category for Thermoplastic-Insulated Wire (ZLGR) in part:

THWN — wire that is suitable for exposure to mineral oil, and to liquid gasoline and gasoline vapors at ordinary

ambient temperature, is marked “Gasoline and Oil Resistant I” if suitable for exposure to mineral oil at 60°C, or “Gasoline and Oil Resistant II” if the compound is suitable for exposure to mineral oil at 75°C. Gasoline-resistant wire has been tested at 23°C when immersed in gasoline. It is considered inherently resistant to gasoline vapors within the limits of the temperature rating of the wire type.

Before using a wire-pulling compound, it should first be investigated to determine compliance with 310.10(G).

## (H) Conductors in Parallel.

**(1) General.** Aluminum, copper-clad aluminum, or copper conductors, for each phase, polarity, neutral, or grounded circuit shall be permitted to be connected in parallel (electrically joined at both ends) only in sizes 1/0 AWG and larger where installed in accordance with 310.10(H)(2) through (H)(6).

Conductors connected in parallel, in accordance with 310.10(H), are treated by the *Code* as a single conductor with a total cross-sectional area of all conductors in parallel. The use of parallel conductors is a practical and cost effective means of installing large-capacity feeders or services. Using conductors larger than 1000 kcmil in raceways is neither economical nor practical unless the conductor size is governed by voltage drop. The ampacity of larger sizes would increase very little in proportion to the increase in the size of the conductor. Where the cross-sectional area of a conductor increases 50 percent (e.g., from 1000 to 1500 kcmil), a Type THW conductor ampacity increases only 80 amperes (less than 15 percent). A 100 percent increase (from 1000 to 2000 kcmil) causes an increase of only 120 amperes (approximately 2 percent). Generally, where cost is a factor, installation of two (or more) paralleled conductors per phase may be beneficial.

The parallel connection of two or more conductors in place of using one large conductor depends on compliance with 310.10(H)(2) to ensure equal current division in order to prevent overloading any of the individual paralleled conductors.

Where individual conductors are tapped from conductors in parallel, the tap connection must include all the conductors in parallel for that particular phase. Tapping into only one of the parallel conductors would result in unbalanced distribution of tap load current between parallel conductors, resulting in one of the conductors carrying more than its share of the load, which could cause overheating and conductor insulation failure. For example, if a 250-kcmil conductor is tapped from a set of two 500-kcmil conductors in parallel, the splicing device must include both 500-kcmil conductors and the single 250-kcmil tap conductor.

*Exception No. 1: Conductors in sizes smaller than 1/0 AWG shall be permitted to be run in parallel to supply control power to indicating instruments, contactors, relays, solenoids, and similar control devices, or for frequencies of 360 Hz and higher, provided all of the following apply:*

- (a) *They are contained within the same raceway or cable.*
- (b) *The ampacity of each individual conductor is sufficient to carry the entire load current shared by the parallel conductors.*
- (c) *The overcurrent protection is such that the ampacity of each individual conductor will not be exceeded if one or more of the parallel conductors become inadvertently disconnected.*

In control wiring and circuits that operate at frequencies greater than 360 Hz, it may be necessary to reduce cable capacitance or voltage drop in long lengths of wire. A 14 AWG conductor might have more than sufficient capacity to carry the load, but by installing two conductors in parallel, the voltage drop can be reduced to acceptable limits. The presence of the word *polarity* in 310.10(H)(1) specifically allows the inclusion of dc circuits.

*Exception No. 2: Under engineering supervision, 2 AWG and 1 AWG grounded neutral conductors shall be permitted to be installed in parallel for existing installations.*

Informational Note to Exception No. 2: Exception No. 2 can be used to alleviate overheating of neutral conductors in existing installations due to high content of triplen harmonic currents.

The word *triplen* refers to a third-order harmonic current, such as the third, sixth, ninth, and so on. The concern is limited to odd-number triplen harmonic currents, such as the third, ninth, and fifteenth, since these are additive currents in the neutral conductor and do not cancel. See Chapter 10 of NFPA 70B-2010, *Recommended Practice for Electrical Equipment Maintenance*, for additional information on power quality and harmonics.

**(2) Conductor Characteristics.** The paralleled conductors in each phase, polarity, neutral, grounded circuit conductor, equipment grounding conductor, or equipment bonding jumper shall comply with all of the following:

- (1) Be the same length
- (2) Consist of the same conductor material
- (3) Be the same size in circular mil area
- (4) Have the same insulation type
- (5) Be terminated in the same manner

To avoid excessive voltage drop and also to ensure equal division of current, it is essential that different phase conductors be located close together and that each phase conductor, grounded conductor, and the grounding conductor (if used) be grouped together in each raceway or cable. However, isolated phase installations are permitted underground where the phase conductors are run in nonmetallic raceways that are in close proximity.

The impedance of a circuit in an aluminum raceway or aluminum-sheathed cable differs from the impedance of the same circuit in a steel raceway or steel-sheathed cable; therefore, separate raceways and cables must have the same physical characteristics. Also, the same number of conductors must be used in each raceway or cable. See 300.20 regarding induced currents in metal enclosures or raceways.

All conductors of the same phase or neutral are required by 310.10(H)(2) to be of the same conductor material. For example, if 12 conductors are paralleled for a 3-phase, 4-wire, 480Y/277-volt ac circuit, 4 conductors could be installed in each of three raceways. The *Code* does not intend that all 12 conductors be copper or aluminum but does intend that the individual conductors in parallel for each phase, grounded conductor, and neutral be the same material, insulation type, length, and so on. Also, the three raceways are intended to have the same physical characteristics (e.g., three rigid aluminum conduits, three steel IMC conduits, three EMTs, or three nonmetallic conduits), not a mixture (e.g., two rigid aluminum conduits and one rigid steel conduit).

The presence of the word *polarity* throughout the section specifically allows the inclusion of dc circuits.

**(3) Separate Cables or Raceways.** Where run in separate cables or raceways, the cables or raceways with conductors shall have the same number of conductors and shall have the same electrical characteristics. Conductors of one phase, polarity, neutral, grounded circuit conductor, or equipment grounding conductor shall not be required to have the same physical characteristics as those of another phase, polarity, neutral, grounded circuit conductor, or equipment grounding conductor.

All raceways or cables are required to be of the same size, material, and length. *Cables*, in this case, means wiring method type cables such as Type MC. For example, the conductors in phases A and B may be copper, and those in phase C may be aluminum.

**(4) Ampacity Adjustment.** Conductors installed in parallel shall comply with the provisions of 310.15(B)(3)(a).

**(5) Equipment Grounding Conductors.** Where parallel equipment grounding conductors are used, they shall be

sized in accordance with 250.122. Sectioned equipment grounding conductors smaller than 1/0 AWG shall be permitted in multiconductor cables in accordance with 310.104, provided the combined circular mil area of the sectioned equipment grounding conductors in each cable complies with 250.122.

**(6) Equipment Bonding Jumpers.** Where parallel equipment bonding jumpers are installed in raceways, they shall be sized and installed in accordance with 250.102.

Item (6) in this list was added to the 2011 *Code* to address the paralleling of equipment bonding jumpers. The equipment bonding jumper size requirements may be different from the requirements for equipment grounding conductors. On the supply side of the service, the size of the bonding jumper is based on 250.66, which is the same requirement as for grounding electrode conductors. On the load side of the service, the size is based on 250.122, which is also the size requirement for equipment grounding conductors. The 1/0 minimum size limitation on paralleled conductors does not apply to the equipment bonding jumper.

### 310.15 Ampacities for Conductors Rated 0–2000 Volts

#### (A) General.

**(1) Tables or Engineering Supervision.** Ampacities for conductors shall be permitted to be determined by tables as provided in 310.15(B) or under engineering supervision, as provided in 310.15(C).

Informational Note No. 1: Ampacities provided by this section do not take voltage drop into consideration. See 210.19(A), Informational Note No. 4, for branch circuits and 215.2(A), Informational Note No. 2, for feeders.

Informational Note No. 2: For the allowable ampacities of Type MTW wire, see Table 13.5.1 in NFPA 79-2007, *Electrical Standard for Industrial Machinery*.

Section 310.15(A)(1) permits two methods for determining conductor ampacity for conductors rated 0 through 2000 volts: selecting the ampacity from a table, using correction factors in the table or notes where necessary, or calculating the ampacity. The latter method can be complex and time consuming and requires engineering supervision. It can, however, result in lower installation costs in some cases, and if calculated properly, it provides a mathematically exact ampacity. See the commentary following 310.15(C) and Informative Annex B for further explanation.

**(2) Selection of Ampacity.** Where more than one ampacity applies for a given circuit length, the lowest value shall be used.

*Exception: Where two different ampacities apply to adjacent portions of a circuit, the higher ampacity shall be permitted to be used beyond the point of transition, a distance equal to 3.0 m (10 ft) or 10 percent of the circuit length figured at the higher ampacity, whichever is less.*

Informational Note: See 110.14(C) for conductor temperature limitations due to termination provisions.

#### Calculation Example

Three 500-kcmil THW conductors in a rigid conduit are run from a motor control center for 12 ft past a heat-treating furnace to a pump motor located 150 ft from the motor control center. Where run in a 78°F to 86°F ambient temperature, the conductors have an ampacity of 380 amperes, per Table 310.15(B)(16). The ambient temperature near the furnace, where the conduit is run, is found to be 113°F, and the length of this particular part of the run is greater than 10 ft and more than 10 percent of the total length of the run at the 78°F to 86°F ambient. Determine the ampacity of the total run in accordance with 310.15(A)(2).

#### Solution

Using the ambient temperature correction factors in Table 310.15(B)(2)(a), the ampacity is calculated:

$$0.82 \times 380 \text{ amperes} = 311.6 \text{ amperes}$$

which is the ampacity of the total run, in accordance with 310.15(A)(2).

Had the run near the furnace at the 113°F ambient been 10 ft or less in length, the ampacity of the entire run would have been 380 amperes, according to the exception to 310.15(A)(2). The heat-sinking effect of the run at the lower ambient temperature would have been sufficient to reduce the temperature of the conductor near the furnace.

**(3) Temperature Limitation of Conductors.** No conductor shall be used in such a manner that its operating temperature exceeds that designated for the type of insulated conductor involved. In no case shall conductors be associated together in such a way, with respect to type of circuit, the wiring method employed, or the number of conductors, that the limiting temperature of any conductor is exceeded.

Most terminations are normally designed for 60°C and/or 75°C maximum temperatures. Because many “over 600 volt” terminations are designed for 90°C, the higher-rated ampacities for conductors of 90°C, 105°C, and so on cannot be used unless the terminals at which the conductors terminate have comparable ratings.

Ambient temperature must also be considered in determining the allowable ampacity of conductors. Tables

310.15(B)(16) through 310.15(B)(20) have ampacity correction factors for ambient temperatures greater or less than the ambient temperature identified in the table heading. To assign the proper ampacity to a conductor in an ambient temperature above 30°C (86°F), the appropriate temperature correction factor must be used. This correction factor is applied in addition to any adjustment factor, such as in 310.15(B)(3)(a).

Conductors that have a rating above the anticipated maximum ambient temperature should be chosen. The operating temperature of conductors should be controlled at or below the conductor rating by coordinating conductor size, number of associated conductors, and ampacity for the particular conductor rating and ambient temperature. All tabulations should be corrected for the anticipated ambient temperature, using the correction factors at the bottom of the ampacity tables. If more than three conductors are associated together, the additional adjustment shown in 310.15(B)(3)(a) must be applied.

#### Calculation Example

Determine the ampacity of 2 AWG THHN copper conductors to be installed in a raceway in an ambient temperature of 50°C (122°F).

#### Solution

Table 310.15(B)(16) shows that the allowable ampacity of the conductor at 30°C is 130 amperes, which is multiplied by 0.82 [taken from the ambient temperature correction factors in Table 310.15(B)(2)(a)]. Thus, the allowable ampacity of the 2 AWG conductor at 50°C is reduced to 106.6 amperes:

$$130 \text{ amperes} \times 0.82 = 106.6 \text{ amperes}$$

For six of these conductors run in the raceway, 310.15(B)(3)(a) requires the allowable ampacity to be further reduced to 80 percent:

$$106.6 \text{ amperes} \times 0.8 = 85.28 \text{ amperes}$$

Under these conditions, the 2 AWG conductors would be suitable for an 80-ampere circuit, based on the standard ampere ratings of circuit breaker and fuses in 240.6(A).

The basis for determining the ampacities of conductors for Tables 310.15(B)(16) and 310.15(B)(17) was the *NEMA Report of Determination of Maximum Permissible Current-Carrying Capacity of Code Insulated Wires and Cables for Building Purposes*, dated June 27, 1938. The basis for determining the ampacities of conductors for Tables 310.15(B)(18) and 310.15(B)(19) and the ampacity tables in Informative Annex B was the Neher–McGrath method. See the commentary following 310.15(C) for further explanation.

Informational Note No. 1: The temperature rating of a conductor [see Table 310.104(A) and Table 310.104(C)] is the maximum temperature, at any location along its length, that the conductor can withstand over a prolonged time period without serious degradation. The allowable ampacity tables, the ampacity tables of Article 310 and the ampacity tables of Informative Annex B, the ambient temperature correction factors in 310.15(B)(2), and the notes to the tables provide guidance for coordinating conductor sizes, types, allowable ampacities, ambient temperatures, and number of associated conductors. The principal determinants of operating temperature are as follows:

- (1) Ambient temperature — ambient temperature may vary along the conductor length as well as from time to time.
- (2) Heat generated internally in the conductor as the result of load current flow, including fundamental and harmonic currents.
- (3) The rate at which generated heat dissipates into the ambient medium. Thermal insulation that covers or surrounds conductors affects the rate of heat dissipation.
- (4) Adjacent load-carrying conductors — adjacent conductors have the dual effect of raising the ambient temperature and impeding heat dissipation.

Informational Note No. 1 to 310.15(A)(3) focuses attention on the necessity for derating conductors where high ambient temperatures are encountered. It also provides helpful information in coordinating ampacities, ambient temperatures, conductor size and number, and so on, to ensure operation at or below the temperature rating.

Item (2) of the informational note explains that heating due to harmonic current should also be considered in determinations of operating temperature. In certain cases, larger-sized conductors may be required. For existing installations, see 310.10(H)(1), Exception No. 2, the following informational note, and the associated commentary.

Informational Note No. 2: Refer to 110.14(C) for the temperature limitation of terminations.

**(B) Tables.** Ampacities for conductors rated 0 to 2000 volts shall be as specified in the Allowable Ampacity Table 310.15(B)(16) through Table 310.15(B)(19), and Ampacity Table 310.15(B)(20) and Table 310.15(B)(21) as modified by 310.15(B)(1) through (B)(7).

The temperature correction and adjustment factors shall be permitted to be applied to the ampacity for the temperature rating of the conductor, if the corrected and adjusted ampacity does not exceed the ampacity for the temperature rating of the termination in accordance with the provisions of 110.14(C).

The ampacity tables in this section have been revised and renumbered for the 2011 *Code*. Each of the tables is identified with a table number that closely ties it to the corre-

sponding *Code* section. For example, former Table 310.16 is now Table 310.15(B)(16). In addition, there are now separate tables for ambient temperature correction factors. Table 310.15(B)(2)(a) is utilized for ambient temperature correction based on 30°C, for use with Tables 310.15(B)(16) and 310.15(B)(17). Table 310.15(B)(2)(b) is employed for ambient temperature correction based on 40°C for use with Tables 310.15(B)(18) and 310.15(B)(19).

Informational Note: Table 310.15(B)(16) through Table 310.15(B)(19) are application tables for use in determining conductor sizes on loads calculated in accordance with Article 220. Allowable ampacities result from consideration of one or more of the following:

- (1) Temperature compatibility with connected equipment, especially the connection points.
- (2) Coordination with circuit and system overcurrent protection.
- (3) Compliance with the requirements of product listings or certifications. See 110.3(B).
- (4) Preservation of the safety benefits of established industry practices and standardized procedures.

Ampacity tables, particularly Table 310.15(B)(16), do not take into account all the many factors affecting ampacity. However, experience over many years has proved the table values to be adequate for loads calculated in accordance with Article 220, because not all of the load diversity occurring in most actual installations is specifically provided for in Article 220. If loads are not calculated in accordance with the requirements of Article 220, the table ampacities, even when corrected in accordance with ambient correction factors and the notes to the tables, might be too high. This result can be particularly true where many cables or raceways are routed close to one another underground. However, load diversity and thermal conductance fill around buried cable could result in increased ampacity. See the commentary following 310.15(C) and Informative Annex B for further information.

The factors in the second column of Table 310.15(B)(3) (a) are based on no diversity, meaning that all conductors in the raceway or cable are loaded to their maximum rated load. The table values can be used, even if there is diversity because the table values would represent a worst case scenario. If there is diversity and a more favorable adjustment factor is desired, a calculation can be performed in accordance with Informative Annex B.

Specific cross references for raceway fill and adjustment factors of 310.15(B)(2) can be found in the informational note following 300.17. For Class 1 conductors, see 725.51; for fire alarm systems, 760.51 and 760.130; for optical fiber cables and raceways, 770.110; and for communications wires and cables within buildings, 800.110.

(1) **General.** For explanation of type letters used in tables and for recognized sizes of conductors for the various conductor insulations, see Table 310.104(A) and Table 310.104(B). For installation requirements, see 310.1 through 310.15(A)(3) and the various articles of this *Code*. For flexible cords, see Table 400.4, Table 400.5(A)(1), and Table 400.5(A)(2).

(2) **Ambient Temperature Correction Factors.** Ampacities for ambient temperatures other than those shown in the ampacity tables shall be corrected in accordance with Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b), or shall be permitted to be calculated using the following equation:

$$I' = I \sqrt{\frac{T_c - T'_a}{T_c - T_a}}$$

where:

- $I'$  = ampacity corrected for ambient temperature
- $I$  = ampacity shown in the tables
- $T_c$  = temperature rating of conductor (°C)
- $T'_a$  = new ambient temperature (°C)
- $T_a$  = ambient temperature used in the table (°C)

(3) **Adjustment Factors.**

(a) *More Than Three Current-Carrying Conductors in a Raceway or Cable.* Where the number of current-carrying

conductors in a raceway or cable exceeds three, or where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a). Each current-carrying conductor of a paralleled set of conductors shall be counted as a current-carrying conductor.

Where conductors of different systems, as provided in 300.3, are installed in a common raceway or cable, the adjustment factors shown in Table 310.15(B)(3)(a) shall apply only to the number of power and lighting conductors (Articles 210, 215, 220, and 230).

The basis for the last paragraph of 310.15(B)(3)(a) is the assumption that the watt loss (heating) from any control and signal conductors in the same raceway or cable will not be enough to significantly increase the temperature of the power and lighting conductors. See 725.48 and 725.133 for limitations on the installation of control and signal conductors in the same raceway or cable as power and lighting conductors.

Informational Note No. 1: See Annex B, Table B.310.15(B)(2)(11), for adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity.

**TABLE 310.15(B)(2)(A) Ambient Temperature Correction Factors Based on 30°C (86°F)**

For ambient temperatures other than 30°C (86°F), multiply the allowable ampacities specified in the ampacity tables by the appropriate correction factor shown below.

Informational Note No. 2: See 366.23(A) for adjustment factors for conductors in sheet metal auxiliary gutters and 376.22(B) for adjustment factors for conductors in metal wireways.

- (1) Where conductors are installed in cable trays, the provisions of 392.80 shall apply.
- (2) Adjustment factors shall not apply to conductors in raceways having a length not exceeding 600 mm (24 in.).
- (3) Adjustment factors shall not apply to underground conductors entering or leaving an outdoor trench if those conductors have physical protection in the form of rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit (PVC), or reinforced thermosetting resin conduit (RTRC) having a length not exceeding 3.05 m (10 ft), and if the number of conductors does not exceed four.

Section 310.15(B)(3)(a)(3) defines conditions under which derating factors do not apply, as illustrated in Exhibit 310.3.

The conductors have physical protection (conduit) that does not exceed 10 ft in length, and the number of conductors does not exceed four.

- (4) Adjustment factors shall not apply to Type AC cable or to Type MC cable under the following conditions:
  - a. The cables do not have an overall outer jacket.
  - b. Each cable has not more than three current-carrying conductors.
  - c. The conductors are 12 AWG copper.
  - d. Not more than 20 current-carrying conductors are installed without maintaining spacing, are stacked, or are supported on “bridle rings.”

#### Calculation Example

A commercial office space requires fourteen 277-volt fluorescent lighting circuits to serve a single open office area.

**EXHIBIT 310.3** An application of 310.15(B)(3)(a)(3).

The office area lighting is assumed to be a continuous load, and the office ambient temperature will not exceed 30°C (86°F). Each circuit will be arranged so that it has a calculated load not exceeding 16 amperes. The selected wiring method is Type MC cable, 3-conductor (with an additional equipment grounding conductor), 12 AWG THHN copper. Each individual MC cable will contain a 3-wire multiwire branch circuit. To serve the entire area, this arrangement requires a total of seven Type MC cables bundled for a distance of about 25 ft, without maintaining spacing between them where they leave the electrical room and enter the office area.

Determine the ampacity of each circuit conductor in accordance with 310.15, applying 310.15(B)(3)(a)(4) to account for the bundled cables. Then determine the maximum branch-circuit overcurrent protection permitted for these bundled MC cables.

#### **Solution**

**STEP 1.** To apply 310.15(B)(3)(a)(4), first determine the quantity of current-carrying conductors. According to 310.15(B)(5), equipment grounding conductors are not counted as current-carrying conductors. According to 310.15(B)(4)(c), fluorescent lighting is considered a nonlinear load, so the grounded conductor of each Type MC cable must be counted as a current-carrying conductor:

$$7 \text{ cables} \times 3 \text{ conductors each} \\ = 21 \text{ current-carrying conductors}$$

Because the quantity of current-carrying conductors exceeds 20, a 60 percent adjustment factor is required by 310.15(B)(3)(a)(5).

**STEP 2.** Determine the ampacity of each current-carrying conductor given the MC cables with more than 20 current-carrying conductors being bundled. From Table 310.15(B)(16):

$$12 \text{ AWG THHN} = 30 \text{ amperes} \\ 30 \text{ amperes} \times 0.60 = 18 \text{ amperes}$$

Because the actual calculated load is 16 amperes of continuous load, 210.19(A)(1) is applicable. The conductors must have an ampacity equal to or greater than the load before the adjustment factor is applied. Because the ampacity of the conductors after the adjustment factor is applied is 18 amperes, no further adjustment is necessary and the conductors are suitable for this installation.

**STEP 3.** Finally, determine the maximum size of the overcurrent protection device permitted for these bundled MC cable branch circuits. Section 240.4(B) permits the use of the next higher standard rating of overcurrent protective device. Therefore, although the conductors have a calculated ampacity of 18 amperes, a 20-ampere overcurrent protective device is permitted. In addition, and of significance, the 20-ampere overcurrent protective device is in compliance with 210.20(A), given that the actual 16-ampere continuous load would require a 20-ampere overcurrent protective device, based on the listing of the overcurrent device.

(5) An adjustment factor of 60 percent shall be applied to Type AC cable or Type MC cable under the following conditions:

- The cables do not have an overall outer jacket.
- The number of current carrying conductors exceeds 20.
- The cables are stacked or bundled longer than 600 mm (24 in) without spacing being maintained.

(b) *More Than One Conduit, Tube, or Raceway.* Spacing between conduits, tubing, or raceways shall be maintained.

Spacing is normally maintained between individual conduits in groups of conduit runs from junction box to junction box because of the need to separate the conduits where they enter the junction box, to allow room for locknuts and bushings.

TABLE 310.15(B)(3)(a) Adjustment Factors for More Than Three Current-Carrying Conductors in a Raceway or Cable

Number of Conductors <sup>1</sup>	Percent of Values in Table 310.15(B)(16) through Table 310.15(B)(19) as Adjusted for Ambient Temperature if Necessary
4–6	80
7–9	70
10–20	50
21–30	45
31–40	40
41 and above	35

<sup>1</sup>Number of conductors is the total number of conductors in the raceway or cable adjusted in accordance with 310.15(B)(5) and (6).

(c) *Circular Raceways Exposed to Sunlight on Rooftops.* Where conductors or cables are installed in circular raceways exposed to direct sunlight on or above rooftops, the adjustments shown in Table 310.15(B)(3)(c) shall be added to the outdoor temperature to determine the applicable ambient temperature for application of the correction factors in Table 310.15(B)(2)(a) or Table 310.15(B)(2)(b).

Informational Note: One source for the average ambient temperatures in various locations is the ASHRAE *Handbook — Fundamentals*.

The conductors in outdoor conduits installed on or near the surface of the roof are subject to a significant increase in temperature when the roof is exposed to direct sunlight. The closer the conduit is to the roof, the greater the ambient temperature adjustment. See the following example and Exhibit 310.4.

Calculation Example

A feeder installed in intermediate metal conduit, Type IMC, supplies a panelboard inside a mechanical room on top of a commercial building in the St. Louis, MO, area, as shown in Exhibit 310.4. The calculated load on the feeder is 175 amperes. The lateral portion of the raceway is secured to elevated supports, crosses the rooftop, and is exposed to sunlight. The elevated supports are not less than 15 in. above the finished rooftop surface. Determine the minimum size circuit conductor using aluminum 90°C XHHW-2 insulation, taking into consideration only the exposure to sunlight. None of the loads are continuous, and the neutral is not considered a current-carrying conductor. The design temperature is based on the averaged June, July, and August 2 percent design temperature from the 2005 ASHRAE Handbook.

EXHIBIT 310.4 An IMC conduit crossing a rooftop and exposed to sunlight. (Courtesy of the International Association of Electrical Inspectors)

Solution

STEP 1. Determine the ambient temperature (compensated for proximity of conduit to the rooftop exposure to sunlight):

- a. Ambient temperature (compensated for proximity of conduit to the rooftop exposure to sunlight) = design temperature + value from Table 310.15(B)(3)(c).
- b. Design temperature for St. Louis area = 94°F.
- c. Temperature adjustment from Table 310.15(B)(3)(c) for a raceway elevated 15 in. above rooftop = 25°F
- d. Compensated ambient temperature:

94°F + 25° F = 119°F

STEP 2. Determine the temperature correction factor for this application.

From Table 310.15(B)(16) for aluminum 90°C XHHW-2 insulated conductors, select the proper temperature correction factor. Using the aluminum 90°C column and the temperature correction factor row for 119°F, the temperature correction factor is 0.82.

STEP 3. Using aluminum 90°C XHHW-2 insulated conductors, determine the proper conductor size to be used in the IMC to supply the 175-ampere load.

- a. Because the load is calculated at 175 amperes noncontinuous, and the neutral conductor is not considered to be a current-carrying conductor, the conductor ampacity is calculated as follows:

175 amperes ÷ 0.82 = 213 amperes

- b. Now, moving back to the 90°C column of Table 310.15(B)(16), select a conductor not less than 213

amperes, or a minimum size conductor of 250-kcmil aluminum XHHW-2:

250-kcmil aluminum XHHW-2

- c. Verify that the conductor ampacity at 75°C is sufficient for the calculated load to comply with terminal temperature requirements of 110.14(C): The 75°C aluminum column of Table 310.16 ampacity equals 205 amperes, which is greater than the 175-ampere calculated load.

Using a very specific set of circumstances, this example demonstrates that roughly an 18 percent loss of usable conductor material occurred. This loss is due solely to high ambient heat present where a cable or raceway is subjected to sunlight and is installed within a specific proximity to the rooftop.

**TABLE 310.15(B)(3)(c) Ambient Temperature Adjustment for Circular Raceways Exposed to Sunlight on or Above Rooftops**

Distance Above Roof to Bottom of Conduit	Temperature Adder	
	°C	°F
0–13 mm (½ in.)	33	60
Above 13 mm (½ in.)–90 mm (3½ in.)	22	40
Above 90 mm (3½ in.)–300 mm (12 in.)	17	30
Above 300 mm (12 in.)–900 mm (36 in.)	14	25

Informational Note to Table 310.15(B)(3)(c): The temperature adders in Table 310.15(B)(3)(c) are based on the results of averaging the ambient temperatures.

**(4) Bare or Covered Conductors.** Where bare or covered conductors are installed with insulated conductors, the temperature rating of the bare or covered conductor shall be equal to the lowest temperature rating of the insulated conductors for the purpose of determining ampacity.

**(5) Neutral Conductor.**

(a) A neutral conductor that carries only the unbalanced current from other conductors of the same circuit shall not be required to be counted when applying the provisions of 310.15(B)(3)(a).

(b) In a 3-wire circuit consisting of two phase conductors and the neutral conductor of a 4-wire, 3-phase, wye-connected system, a common conductor carries approximately the same current as the line-to-neutral load currents of the other conductors and shall be counted when applying the provisions of 310.15(B)(3)(a).

(c) On a 4-wire, 3-phase wye circuit where the major portion of the load consists of nonlinear loads, harmonic currents are present in the neutral conductor; the neutral conductor shall therefore be considered a current-carrying conductor.

During the 1996 *NEC* development cycle, a task group composed of interested parties was created to recommend to the National Electrical Code Committee the direction it should take to improve the safeguarding of persons and property from conditions that can be introduced by nonlinear loads. This group was designated the NEC Correlating Committee Ad Hoc Subcommittee on Nonlinear Loads. The scope of the subcommittee was as follows:

1. To study the effects of electrical loads producing substantial current distortion upon electrical system distribution components including but not limited to
  - a. Distribution transformers, current transformers, and others
  - b. Switchboards and panelboards
  - c. Phase and neutral feeder conductors
  - d. Phase and neutral branch-circuit conductors
  - e. Proximate data and communications conductors
2. To study harmful effects, if any, to the system components from overheating resulting from these load characteristics
3. To make recommendations for methods to minimize the harmful effects of nonlinear loads considering all means, including compensating methods at load sources
4. To prepare proposals, if necessary, to amend the 1996 *National Electrical Code*, where amelioration of fire safety may be achieved

The subcommittee reviewed technical literature and electrical theory on the fundamental nature of harmonic distortion, as well as the requirements in and proposals for the 1993 *NEC* regarding nonlinear loads. The subcommittee concluded that, while nonlinear loads can cause undesirable operational effects, including additional heating, no significant threat to persons and property had been substantiated.

The subcommittee agreed with the existing *Code* text regarding nonlinear loads. However, the subcommittee submitted many proposals, including a definition of *nonlinear load*, revised text reflecting that definition, informational notes calling attention to the effects of nonlinear loads, and proposals permitting the paralleling of neutral conductors in existing installations under engineering supervision.

**Should Neutral Conductors Be Oversized?**

There is concern that, because the theoretical maximum neutral current is 1.73 times the balanced phase conductor

current, potential exists for neutral conductors to overheat in 3-phase, 4-wire, wye-connected power systems. The subcommittee acknowledged this theoretical basis, although a review of documented information could not identify fires attributed to the use of nonlinear loads.

The subcommittee reviewed all available data regarding measurements of circuits that contain nonlinear loads. The data were obtained from consultants, equipment manufacturers, and testing laboratories and included hundreds of feeder and branch circuits involving 3-phase, 4-wire, wye-connected systems with nonlinear loads. The data revealed that many circuits had neutral conductor current greater than the phase conductor current, and approximately 5 percent of all circuits reported had neutral conductor current exceeding 125 percent of the highest phase conductor current. One documented survey with data collected in 1988 from 146 3-phase computer power system sites determined that 3.4 percent of the sites had neutral current in excess of the rated system full-load current.

According to 210.19(A)(1) and 215.2(A)(1), the total continuous load on any overcurrent device located in a panelboard should not exceed 80 percent of its rating (the exception being assemblies listed for continuous operation at 100 percent of their rating). Because the neutral conductor is usually not connected to an overcurrent device, derating for continuous operation is not necessary. Therefore, the neutral conductor ampacity is usually 125 percent of the maximum continuous current allowed by the overcurrent device. Both 210.19(A)(1) and 215.2(A)(1) include an exception that permits a branch circuit or a feeder neutral conductor to be sized at 100 percent of the noncontinuous load plus the continuous load, thus permitting a reduction in a neutral conductor size (calculated from previous editions) by as much as 25 percent.

Also important for gathering electrically measured data from existing installations is the measurement of nonsinusoidal voltages and currents.

#### Measurement of Nonsinusoidal Voltages and Currents

The measurement of nonsinusoidal voltages and currents may require instruments different from some meters used to measure sinusoidal waveforms. Many voltage and current meters respond only to the peak value of a waveform and indicate a value equivalent to the rms value of a sinusoidal waveform. For a sinusoidal waveform, the rms value is 70.7 percent of the peak value. Meters of this type, known as “average responding meters,” give a true indication only if the waveform being measured is sinusoidal. Both analog and digital meters may be average responding instruments. Voltages and currents that are nonsinusoidal, such as those with harmonic frequencies, cannot be accurately measured using

an average responding meter. Only a meter that measures “true rms” can be used to correctly measure the rms value of a nonsinusoidal waveform.

Exhibit 310.5 illustrates a clamp-on ammeter that uses true rms measurements. Exhibit 310.6 is an example of a portable diagnostic analyzer used for more sophisticated power measurements, including measuring harmonic distortion.

**EXHIBIT 310.5** A clamp-on ammeter that uses true rms measurements. This is an example of one solution to 310.15(B)(4)(c), where accurate measurement of neutral current becomes necessary. (Courtesy of Fluke Corp.)

**(6) Grounding or Bonding Conductor.** A grounding or bonding conductor shall not be counted when applying the provisions of 310.15(B)(3)(a).

**(7) 120/240-Volt, 3-Wire, Single-Phase Dwelling Services and Feeders.** For individual dwelling units of one-family, two-family, and multifamily dwellings, conductors, as listed in Table 310.15(B)(7), shall be permitted as 120/240-volt,

**EXHIBIT 310.6** A portable tool for such tasks as diagnostic power analysis, including harmonic distortion. This is one example of a more advanced solution to 310.15(B)(5)(c), where accurate measurement and thorough circuit analysis is desirable. (Courtesy of Dranetz-BMI)

**TABLE 310.15(B)(7) Conductor Types and Sizes for 120/240-Volt, 3-Wire, Single-Phase Dwelling Services and Feeders. Conductor Types RHH, RHW, RHW-2, THHN, THHW, THW, THW-2, THWN, THWN-2, XHHW, XHHW-2, SE, USE, USE-2**

Service or Feeder Rating (Amperes)	Conductor (AWG or kcmil)	
	Copper	Aluminum or Copper-Clad Aluminum
100	4	2
110	3	1
125	2	1/0
150	1	2/0
175	1/0	3/0
200	2/0	4/0
225	3/0	250
250	4/0	300
300	250	350
350	350	500
400	400	600

3-wire, single-phase service-entrance conductors, service-lateral conductors, and feeder conductors that serve as the main power feeder to each dwelling unit and are installed in raceway or cable with or without an equipment grounding conductor. For application of this section, the main power feeder shall be the feeder between the main disconnect and the panelboard that supplies, either by branch circuits or by feeders, or both, all loads that are part or associated with the

dwelling unit. The feeder conductors to a dwelling unit shall not be required to have an allowable ampacity rating greater than their service-entrance conductors. The grounded conductor shall be permitted to be smaller than the ungrounded conductors, provided the requirements of 215.2, 220.61, and 230.42 are met.

Section 310.15(B)(7) permits the main feeder to a dwelling unit to be sized according to the conductor sizes in Table 310.15(B)(7). The permission to use this table applies only to conductors carrying 100 percent of the dwelling unit's diversified load.

Provided a single set of 3-wire, single-phase, service-entrance conductors in raceway or cable supplies a one-family, two-family, or multifamily dwelling, the reduced conductor size permitted by 310.15(B)(7) is applicable to the service-entrance conductors, service-lateral conductors, or feeder conductors that supply the main power feeder to a dwelling unit. The feeder conductors to a dwelling unit are not required to be larger than its service-entrance conductors.

Exhibits 310.7 and 310.8 illustrate the application of 310.15(B)(7). In Exhibit 310.7, the reduced conductor size permitted is applicable only to the service-entrance conductors run to each apartment from the meters. In Exhibit 310.8,

**EXHIBIT 310.7** One application of 310.15(B)(7), where the reduced conductor size is applicable to the service-entrance conductors.

**EXHIBIT 310.8** A second application of 310.15(B)(7), where the reduced conductor size is applicable to the service-entrance conductors and to the feeder conductors.

the reduced conductor size permitted is also applicable to the feeder conductors run to each apartment from the service disconnecting means, because these feeders carry the entire load to each apartment and are considered to be the main power feeder to each apartment.

**(C) Engineering Supervision.** Under engineering supervision, conductor ampacities shall be permitted to be calculated by means of the following general equation:

$$I = \sqrt{\frac{T_c - T_a}{R_{dc}(1 + Y_c)R_{ca}}} \times 10^3 \text{ amperes}$$

where:

- $T_c$  = conductor temperature in degrees Celsius (°C)
- $T_a$  = ambient temperature in degrees Celsius (°C)
- $R_{dc}$  = dc resistance of conductor at temperature  $T_c$
- $Y_c$  = component ac resistance resulting from skin effect and proximity effect
- $R_{ca}$  = effective thermal resistance between conductor and surrounding ambient

The formula in 310.15(C) was developed by J. H. Neher and M. H. McGrath to determine conductor ampacity. A descrip-

tion of this calculation method was given in AIEE paper No. 5-660, "The Calculation of the Temperature Rise and Load Capability of Cable Systems," by Neher and McGrath. This paper was published in *AIEE Transactions, Part III (Power Apparatus and Systems)*, Vol. 76, October 1957, pp. 752–772. The AIEE (American Institute of Electrical Engineers) is now the Institute of Electrical and Electronics Engineers (IEEE).

The Neher–McGrath formula in 310.15(C) is a heat-transfer formula, comprising a series of heat-transfer calculations, that takes into account all heat sources and the thermal resistances between the heat sources and free air. The most common use of the Neher–McGrath formula is for calculation of conductor ampacity in underground electrical ducts (raceways), although the formula is applicable to all conductor installations.

Current passing through a conductor produces losses in the form of heat, which appears as a temperature rise in the conductor. This heat must pass through the cable insulation, the air in the raceway, and the raceway itself to the surrounding medium, usually earth or concrete, where it is dissipated into the air by radiation and convection. Unless the heat is dissipated, the temperature in the conductor will exceed the rating of the conductor insulation. The conductor's ampacity is based on the rate of heat dissipation through the thermal resistances surrounding the conductor. Because of the many variables and the complexities of the many formulas involved, the *Code* requires the calculation to be made under engineering supervision. There are a number of factors that will affect heat dissipation, each of which will affect the final conductor ampacity. For conductors in underground electrical ducts, there are several heat sources, as follows, and as illustrated in Exhibit 310.9:

1. *Conductor losses due to the load current  $I^2R$ .* These losses vary with the load current, conductor material, and conductor cross-sectional area (conductor size).
2. *Skin-effect heating if the current is alternating current.* The heat developed by the skin effect is due to the shape of the conductor and is based on the configuration of the conductors (i.e., solid, stranded, or compact).
3. *Hysteresis losses if the duct is steel or other magnetic material.* These losses are dependent on the magnetic properties of the electrical duct and the shape of the duct.
4. *Heating from other conductors in the duct.* This heating is based on the number, location, and proximity of other conductors as well as the losses in the other conductors. The more conductors in the raceway, the greater the heating effect from these conductors is likely to be. This factor replaces the adjustment factors in 310.15(B)(3)(a) to the ampacity tables.

**EXHIBIT 310.9** Heat source for conductors and thermal barriers (resistances) to heat dissipation in underground electrical ducts.

5. *Mutual heating from other ducts, cables, and so forth, in the vicinity.* The closer the other heat sources and the more they surround the duct for which calculations are being made, the greater the heating effect. For example, in the case of a symmetrical nine-duct bank, three ducts high and three ducts wide, the center duct will receive the most heat as a result of mutual heating.

Heat generated by the following various types of losses is conducted through the different thermal barriers or resistances, as illustrated in Exhibit 310.9.

**Conductor Insulation.** The conductor insulation also serves as a good thermal insulator. It presents a thermal resistance to heat generated by the conductor due to the  $I^2R$  losses, including any dielectric losses. This thermal resistance value depends on the thickness of the insulation and the type of insulating material used. Materials such as polyvinyl chloride, used in Type THW and other conductors; cross-linked polyethylene, used in Type XHHW and other conductors; and rubber, used in Type RHW and other conductors, have different thermal resistivities. In addition, the thickness of the conductor insulation varies from one type of insulation to another, even for the same size conductor.

**Airspace.** The next thermal barrier encountered by the heat flow generated in the conductor is the airspace between the conductor insulation and the surrounding wall or raceway. The thermal resistance of this airspace is based on the num-

ber of conductors in the duct, the assumed mean value of the temperature of the air in the duct, and the constants provided in the Neher–McGrath paper, which were determined from experimental data.

**Duct Wall.** After it passes through the airspace around the conductors, the heat encounters the thermal resistance of the duct wall. This thermal resistance is based on the thermal resistivity of the type of material used and the thickness of the duct wall. Metallic materials have less thermal resistance than nonmetallic materials. The thicker the wall, the greater the thermal resistance.

**Earth Backfill.** The thermal resistance that must be considered next is that offered by the earth or other backfill material above the duct. This resistance incorporates not only the thermal resistivity and ambient temperature of the earth but also the number of current-carrying conductors within the duct, the outside diameter of the duct, the burial depth, a loss factor, and the mutual heating factor caused by other nearby ducts. The deeper the duct is buried, the greater the thermal resistance.

To prevent the temperature of the conductors from exceeding the rated temperature of the insulation, heat dissipation through thermal resistances must be equal to or greater than the heat developed. Thus, the thermal resistances of all the components of a conductor must be determined, and the allowable temperature differential above the ambient temperature and between the conductors and the surface of the earth must be known.

### 310.60 Conductors Rated 2001 to 35,000 Volts

#### (A) Definitions.

**Electrical Ducts.** As used in Article 310, electrical ducts shall include any of the electrical conduits recognized in Chapter 3 as suitable for use underground; other raceways round in cross section, listed for underground use, and embedded in earth or concrete.

The term *electrical ducts* is used to differentiate them from other ducts, for example, those used for air handling. The term is intended to include nonmetallic electrical ducts commonly used for underground wiring, as well as other raceways (e.g., rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit, and high density polyethylene conduit) listed for use underground in earth or concrete.

**Thermal Resistivity.** As used in this *Code*, the heat transfer capability through a substance by conduction. It is the reciprocal of thermal conductivity and is designated Rho and expressed in the units °C-cm/watt.

#### (B) Ampacities of Conductors Rated 2001 to 35,000 Volts.

Ampacities for solid dielectric-insulated conductors shall be permitted to be determined by tables or under engineering supervision, as provided in 310.60(C) and (D).

**(1) Selection of Ampacity.** Where more than one calculated or tabulated ampacity could apply for a given circuit length, the lowest value shall be used.

*Exception:* Where two different ampacities apply to adjacent portions of a circuit, the higher ampacity shall be permitted to be used beyond the point of transition, a distance equal to 3.0 m (10 ft) or 10 percent of the circuit length calculated at the higher ampacity, whichever is less.

Informational Note: See 110.40 for conductor temperature limitations due to termination provisions.

**(C) Tables.** Ampacities for conductors rated 2001 to 35,000 volts shall be as specified in Table 310.60(C)(67) through Table 310.60(C)(86). Ampacities for ambient temperatures other than those specified in the ampacity tables shall be corrected in accordance with 310.60(C)(4).

Informational Note No. 1: For ampacities calculated in accordance with 310.60(B), reference IEEE 835-1994 (IPCEA Pub. No. P-46-426), *Standard Power Cable Ampacity Tables*, and the references therein for availability of all factors and constants.

Informational Note No. 2: Ampacities provided by this section do not take voltage drop into consideration. See 210.19(A), Informational Note No. 4, for branch circuits and 215.2(A), Informational Note No. 2, for feeders.

**(1) Grounded Shields.** Ampacities shown in Table 310.60(C)(69), Table 310.60(C)(70), Table 310.60(C)(81), and Table 310.60(C)(82) are for cable with shields grounded at one point only. Where shields are grounded at more than one point, ampacities shall be adjusted to take into consideration the heating due to shield currents.

**(2) Burial Depth of Underground Circuits.** Where the burial depth of direct burial or electrical duct bank circuits is modified from the values shown in a figure or table, ampacities shall be permitted to be modified as indicated in (C)(2)(a) and (C)(2)(b).

(a) Where burial depths are increased in part(s) of an electrical duct run, no decrease in ampacity of the conductors is needed, provided the total length of parts of the duct run increased in depth is less than 25 percent of the total run length.

(b) Where burial depths are deeper than shown in a specific underground ampacity table or figure, an ampacity de-rating factor of 6 percent per 300-mm (1-ft) increase in depth for all values of rho shall be permitted.

No rating change is needed where the burial depth is decreased.

**(3) Electrical Ducts in Figure 310.60.** At locations where electrical ducts enter equipment enclosures from underground, spacing between such ducts, as shown in Figure

310.60, shall be permitted to be reduced without requiring the ampacity of conductors therein to be reduced.

**(4) Ambient Temperature Correction.** Ampacities for ambient temperatures other than those specified in the ampacity tables shall be corrected in accordance with Table 310.60(C)(4)(4) or shall be permitted to be calculated using the following equation:

$$I' = I \sqrt{\frac{T_c - T_a'}{T_c - T_a}}$$

where:

$I'$  = ampacity corrected for ambient temperature

$I$  = ampacity shown in the table for  $T_c$  and  $T_a$

$T_c$  = temperature rating of conductor (°C)

$T_a'$  = new ambient temperature (°C)

$T_a$  = ambient temperature used in the table (°C)

**(D) Engineering Supervision.** Under engineering supervision, conductor ampacities shall be permitted to be calculated by using the following general equation:

$$I = \sqrt{\frac{T_c - (T_a + \Delta T_d)}{R_{dc} (1 + Y_c) R_{ca}}} \times 10^3 \text{ amperes}$$

where:

$T_c$  = conductor temperature (°C)

$T_a$  = ambient temperature (°C)

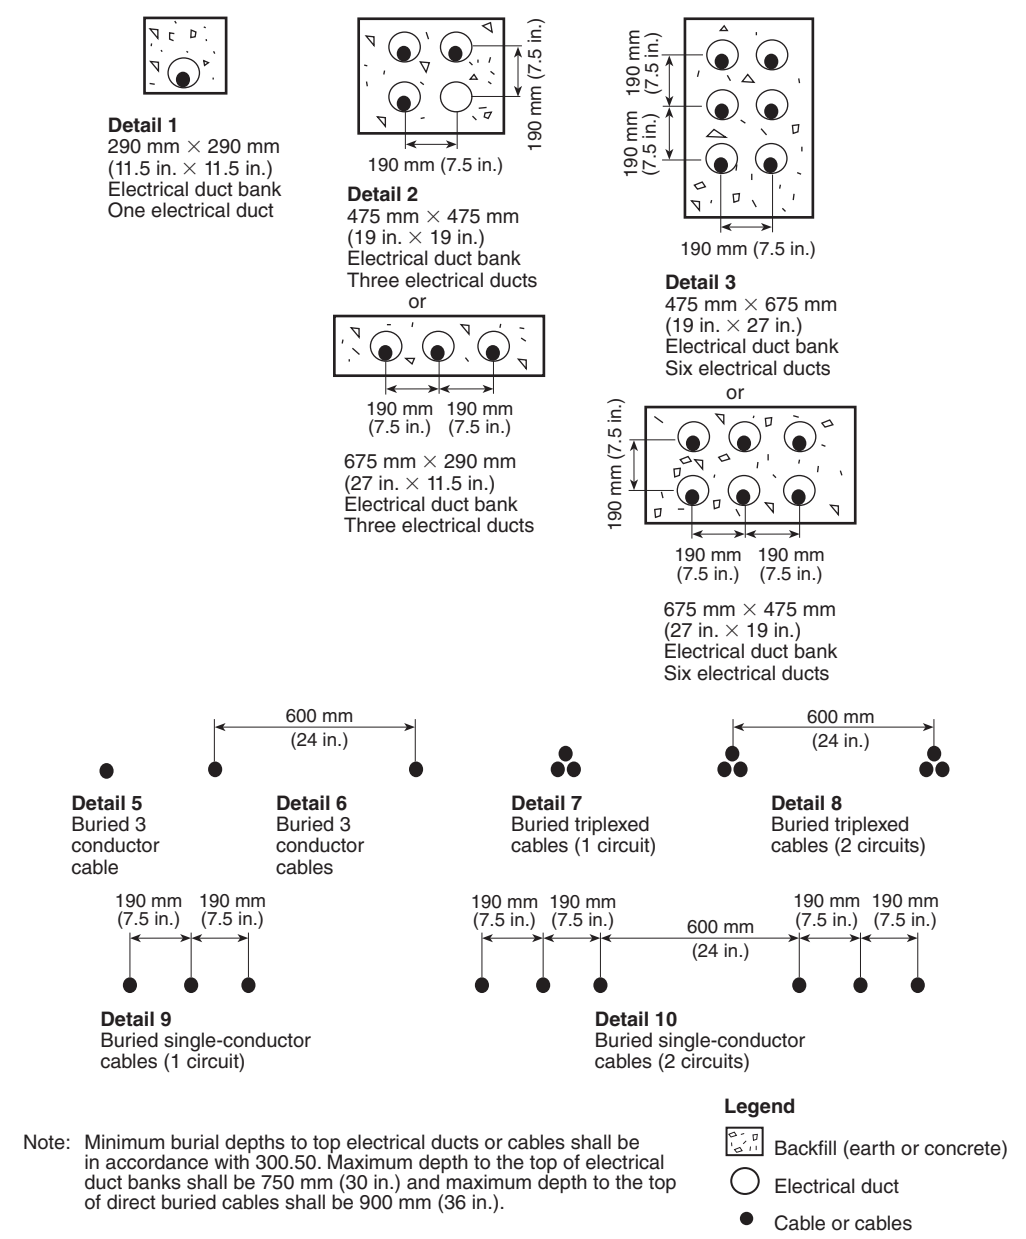

$\Delta T_d$  = dielectric loss temperature rise

$R_{dc}$  = dc resistance of conductor at temperature  $T_c$

$Y_c$  = component ac resistance resulting from skin effect and proximity effect

$R_{ca}$  = effective thermal resistance between conductor and surrounding ambient

Informational Note: The dielectric loss temperature rise ( $\Delta T_d$ ) is negligible for single circuit extruded dielectric cables rated below 46 kV.

**FIGURE 310.60** Cable Installation Dimensions for Use with Table 310.60(C)(77) Through Table 310.60(C)(86).

**TABLE 310.60(C)(4) Ambient Temperature Correction Factors**

For ambient temperatures other than 40°C (104°F), multiply the allowable ampacities specified in the ampacity tables by the appropriate factor shown below.			
Ambient Temperature (°C)	Temperature Rating of Conductor		Ambient Temperature (°F)
	90°C	105°C	
10 or less	1.26	1.21	50 or less
11–15	1.22	1.18	51–59
16–20	1.18	1.14	60–68
21–25	1.14	1.11	69–77
26–30	1.10	1.07	78–86
31–35	1.05	1.04	87–95
36–40	1.00	1.00	96–104
41–45	0.95	0.96	105–113

### III. Construction Specifications

#### 310.104 Conductor Constructions and Applications

Insulated conductors shall comply with the applicable provisions of Table 310.104(A) through Table 310.104(E).

Informational Note: Thermoplastic insulation may stiffen at temperatures lower than  $-10^{\circ}\text{C}$  ( $+14^{\circ}\text{F}$ ). Thermoplastic insulation may also be deformed at normal temperatures where subjected to pressure, such as at points of support. Thermoplastic insulation, where used on dc circuits in wet locations, may result in electroendosmosis between conductor and insulation.

The primary information in Tables 310.104(A) through Table 310.104(E) is the minimum required insulation thickness for each insulation type and voltage level. Additional detailed wire classification information for sizes 14 AWG through 2000 kcmil is available in standards and directories such as those published by Underwriters Laboratories Inc.

Table 310.104(A) includes conductor applications and maximum operating temperatures. It also lists some conductors that have dual ratings, such as Type XHHW, which is rated  $90^{\circ}\text{C}$  for dry and damp locations and  $75^{\circ}\text{C}$  for wet locations, and Type THW, which is rated  $75^{\circ}\text{C}$  for dry and wet locations and  $90^{\circ}\text{C}$  for special applications within electric-discharge lighting equipment.

Types RHW-2, XHHW-2, and other types identified by the suffix “2” are rated  $90^{\circ}\text{C}$  for wet locations as well as dry and damp locations.

Copper-clad aluminum conductors are drawn from a copper-clad aluminum rod with the copper metallurgically bonded to an aluminum core. The copper forms a minimum of 10 percent of the cross-sectional area of a solid conductor or of each strand of a stranded conductor. See the commentary following 310.106(B) for making electrical connections with different types of conductor material. A comparison of the characteristics of copper, copper-clad aluminum, and aluminum conductors can be made from Commentary Table 310.2.

#### 310.106 Conductors

All “insulated” conductors are not equal. Only wires and cables that meet the minimum fire, electrical, and physical properties required by the applicable standards are permitted to be marked with the letter designations found in Tables 310.104(A) through (C). See 310.104 for the requirements of insulated conductor construction and applications.

<sup>1</sup> Some insulations do not require an outer covering.<sup>2</sup> Where design conditions require maximum conductor operating temperatures above 90°C (194°F).<sup>3</sup> For signaling circuits permitting 300-volt insulation.<sup>4</sup> Includes integral jacket.<sup>5</sup> For ampacity limitation, see 340.80.<sup>6</sup> Insulation thickness shall be permitted to be 2.03 mm (80 mils) for listed Type USE conductors that have been subjected to special investigations. The nonmetallic covering over individual rubber-covered conductors of aluminum-sheathed cable and of lead-sheathed or multiconductor cable shall not be required to be flame retardant. For Type MC cable, see 330.104. For nonmetallic-sheathed cable, see Article 334, Part III. For Type UF cable, see Article 340, Part III.

<sup>1</sup>**100 Percent Insulation Level.** Cables in this category shall be permitted to be applied where the system is provided with relay protection such that ground faults will be cleared as rapidly as possible but, in any case, within 1 minute. While these cables are applicable to the great majority of cable installations that are on grounded systems, they shall be permitted to be used also on other systems for which the application of cables is acceptable, provided the above clearing requirements are met in completely de-energizing the faulted section.

<sup>2</sup>**133 Percent Insulation Level.** This insulation level corresponds to that formerly designated for ungrounded systems. Cables in this category shall be permitted to be applied in situations where the clearing time requirements of the 100 percent level category cannot be met and yet there is adequate assurance that the faulted section will be de-energized in a time not exceeding 1 hour. Also, they shall be permitted to be used in 100 percent insulation level applications where additional insulation is desirable.

<sup>3</sup>**173 Percent Insulation Level.** Cables in this category shall be permitted to be applied under all of the following conditions:

- (1) In industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation
- (2) Where the fault clearing time requirements of the 133 percent level category cannot be met
- (3) Where an orderly shutdown is essential to protect equipment and personnel
- (4) There is adequate assurance that the faulted section will be de-energized in an orderly shutdown

Also, cables with this insulation thickness shall be permitted to be used in 100 or 133 percent insulation level applications where additional insulation strength is desirable.

**(A) Minimum Size of Conductors.** The minimum size of conductors shall be as shown in Table 310.106(A), except as permitted elsewhere in this *Code*.

Section 310.106 requires the minimum conductor sizes listed in Table 310.106(A), except as permitted in other sections, such the following.

1. Small conductor sizes 18 and 16 AWG as permitted by 240.4(D)(1) and (2)
2. Flexible cords as permitted by Table 400.4
3. Fixture wire as permitted by 402.6
4. Motors rated 1 hp or less as permitted by 430.22(F)

**TABLE 310.106(A) Minimum Size of Conductors**

Conductor Voltage Rating (Volts)	Minimum Conductor Size (AWG)	
	Copper	Aluminum or Copper-Clad Aluminum
0–2000	14	12
2001–5000	8	8
5001–8000	6	6
8001–15,000	2	2
15,001–28,000	1	1
28,001–35,000	1/0	1/0

5. Cranes and hoists as permitted by 610.14
6. Elevator control and signaling circuits as permitted by 620.12
7. Class 1, Class 2, and Class 3 circuits as permitted by 725.49(A) and 725.127, Exception
8. Fire alarm circuits as permitted by 760.49(A); 760.127, Exception; and 760.179(B)
9. Motor-control circuits as permitted by 430.72
10. Control and instrumentation circuits as permitted by 727.6
11. Electric signs and outline lighting as permitted in 600.31(B) and 600.32(B)

**(B) Conductor Material.** Conductors in this article shall be of aluminum, copper-clad aluminum, or copper unless otherwise specified.

Solid aluminum conductors 8, 10, and 12 AWG shall be made of an AA-8000 series electrical grade aluminum alloy conductor material. Stranded aluminum conductors 8 AWG through 1000 kcmil marked as Type RHH, RHW, XHHW, THW, THHW, THWN, THHN, service-entrance Type SE Style U and SE Style R shall be made of an AA-8000 series electrical grade aluminum alloy conductor material.

Section 310.106(B) provides recognition of approved AA-8000 series electrical-grade aluminum alloy conductor materials for wire and cable products. It also provides coordination with the UL listing requirements for testing terminations, such as CO/ALR devices and other connectors, suitable for use with aluminum conductors. The electrical industry has developed AA-8000 series aluminum alloy materials and the connectors suitable for use with aluminum conductors to provide for safe and stable connections. Connections suitable for use with aluminum conductors are also generally listed as suitable for use with copper conductors and are marked accordingly, such as AL7CU or AL9CU. Numbers 7 and 9 identify the temperature ratings of 75°C and 90°C, respectively, for these connectors.

**(C) Stranded Conductors.** Where installed in raceways, conductors 8 AWG and larger, not specifically permitted or required elsewhere in this *Code* to be solid, shall be stranded.

Large-size conductors are required to be stranded to provide greater flexibility. This requirement does not apply to conductors outside of raceways, such as busbars and the conductors of Type MI mineral-insulated metal-sheathed cable. Special applications elsewhere in the *Code* may require or permit different requirements for stranded conductors. For example, the bonding conductors of a permanently installed

swimming pool are required to be solid copper conductors of 8 AWG or larger, according to 680.26(B).

**(D) Insulated.** Conductors, not specifically permitted elsewhere in this *Code* to be covered or bare, shall be insulated.

Informational Note: See 250.184 for insulation of neutral conductors of a solidly grounded high-voltage system.

### 310.110 Conductor Identification

**(A) Grounded Conductors.** Insulated or covered grounded conductors shall be identified in accordance with 200.6.

**(B) Equipment Grounding Conductors.** Equipment grounding conductors shall be in accordance with 250.119.

**(C) Ungrounded Conductors.** Conductors that are intended for use as ungrounded conductors, whether used as a single conductor or in multiconductor cables, shall be finished to be clearly distinguishable from grounded and grounding conductors. Distinguishing markings shall not conflict in any manner with the surface markings required by 310.120(B)(1). Branch-circuit ungrounded conductors shall be identified in accordance with 210.5(C). Feeders shall be identified in accordance with 215.12.

The identification requirements apply only where a premises wiring system has circuits from more than one nominal voltage system. See the commentary following 210.5(C) and 215.12 for additional information.

*Exception: Conductor identification shall be permitted in accordance with 200.7.*

Ungrounded conductors with white or gray insulation are permitted if the conductors are permanently re-identified at termination points and are visible and accessible. The normal methods of re-identification include colored tape, tagging, or paint. Other applications where white conductors are permitted include flexible cords and circuits less than 50 volts. A white conductor used in single-pole, 3-way and 4-way switch loops also requires re-identification (a color other than white, gray, or green) if it is used as an ungrounded conductor. See 200.7(C)(2) for further information about re-identification of conductors.

### 310.120 Marking

**(A) Required Information.** All conductors and cables shall be marked to indicate the following information, using the applicable method described in 310.120(B):

- (1) The maximum rated voltage.
- (2) The proper type letter or letters for the type of wire or cable as specified elsewhere in this *Code*.
- (3) The manufacturer's name, trademark, or other distinctive marking by which the organization responsible for the product can be readily identified.
- (4) The AWG size or circular mil area.

Informational Note: See Conductor Properties, Table 8 of Chapter 9, for conductor area expressed in SI units for conductor sizes specified in AWG or circular mil area.

- (5) Cable assemblies where the neutral conductor is smaller than the ungrounded conductors shall be so marked.

#### (B) Method of Marking.

(1) **Surface Marking.** The following conductors and cables shall be durably marked on the surface. The AWG size or circular mil area shall be repeated at intervals not exceeding 610 mm (24 in.). All other markings shall be repeated at intervals not exceeding 1.0 m (40 in.).

- (1) Single-conductor and multiconductor rubber- and thermoplastic-insulated wire and cable
- (2) Nonmetallic-sheathed cable
- (3) Service-entrance cable
- (4) Underground feeder and branch-circuit cable
- (5) Tray cable
- (6) Irrigation cable
- (7) Power-limited tray cable
- (8) Instrumentation tray cable

(2) **Marker Tape.** Metal-covered multiconductor cables shall employ a marker tape located within the cable and running for its complete length.

*Exception No. 1:* Type MI cable.

*Exception No. 2:* Type AC cable.

*Exception No. 3:* The information required in 310.120(A) shall be permitted to be durably marked on the outer nonmetallic covering of Type MC, Type ITC, or Type PLTC cables at intervals not exceeding 1.0 m (40 in.).

*Exception No. 4:* The information required in 310.120(A) shall be permitted to be durably marked on a nonmetallic covering under the metallic sheath of Type ITC or Type PLTC cable at intervals not exceeding 1.0 m (40 in.).

Type PLTC cable may have a metallic sheath or armor over a nonmetallic jacketed cable. A second nonmetallic jacket

covering the metallic sheath is optional. Exceptions No. 3 and No. 4 define the marking requirements for either case.

Informational Note: Included in the group of metal-covered cables are Type AC cable (Article 320), Type MC cable (Article 330), and lead-sheathed cable.

(3) **Tag Marking.** The following conductors and cables shall be marked by means of a printed tag attached to the coil, reel, or carton:

- (1) Type MI cable
- (2) Switchboard wires
- (3) Metal-covered, single-conductor cables
- (4) Type AC cable

(4) **Optional Marking of Wire Size.** The information required in 310.120(A)(4) shall be permitted to be marked on the surface of the individual insulated conductors for the following multiconductor cables:

- (1) Type MC cable
- (2) Tray cable
- (3) Irrigation cable
- (4) Power-limited tray cable
- (5) Power-limited fire alarm cable
- (6) Instrumentation tray cable

(C) **Suffixes to Designate Number of Conductors.** A type letter or letters used alone shall indicate a single insulated conductor. The letter suffixes shall be indicated as follows:

- (1) D — For two insulated conductors laid parallel within an outer nonmetallic covering
- (2) M — For an assembly of two or more insulated conductors twisted spirally within an outer nonmetallic covering

(D) **Optional Markings.** All conductors and cables contained in Chapter 3 shall be permitted to be surface marked to indicate special characteristics of the cable materials. These markings include, but are not limited to, markings for limited smoke, sunlight resistant, and so forth.

Cable insulations that have special characteristics are permitted to carry surface markings that indicate their characteristics. For example, the limited-smoke cables are permitted to be marked "LS" or "ST1." Other characteristics that are permitted to be marked include sunlight resistance and low corrosivity. For a detailed list of optional wire and cable marking, see the *UL Wire Marking Guide*, available from Underwriters Laboratories Inc.

#### 312.1 Scope

This article covers the installation and construction specifications of cabinets, cutout boxes, and meter socket enclosures.

Cabinets and cutout boxes are designed with a swinging door(s) to enclose potential transformers, current transformers, switches, overcurrent devices, meters, or control equipment. (See the definitions of these terms in Article 100.) Cabinets and cutout boxes are required to be of sufficient size to accommodate all devices and conductors without overcrowding or jamming. This condition can be prevented by thoughtful planning and routing of conductors, cables, and conduits and through the use of auxiliary gutters (Article 366).

The serving electric utility often has equipment specifications or service requirements beyond the *Code* for meter sockets, metering cabinets, and metering compartments within switchgear, switchboards, and panelboards. Consulting with the local electric utility on these requirements helps identify suitable equipment for an installation. One organization, the Electric Utility Service Equipment Requirements Committee (EUSERC), promotes uniform electric utility metering service requirements for these enclosures that meet the requirements of the *Code* and the serving utility. Many electrical equipment manufacturers identify their equipment as meeting the EUSERC metering space requirements.

#### I. Installation

##### 312.2 Damp and Wet Locations

In damp or wet locations, surface-type enclosures within the scope of this article shall be placed or equipped so as to prevent moisture or water from entering and accumulating within the cabinet or cutout box, and shall be mounted so there is at least 6-mm ( $\frac{1}{4}$ -in.) airspace between the enclosure and the wall or other supporting surface. Enclosures installed in wet locations shall be weatherproof. For enclosures in wet locations, raceways or cables entering above the level of uninsulated live parts shall use fittings listed for wet locations.

*Exception: Nonmetallic enclosures shall be permitted to be installed without the airspace on a concrete, masonry, tile, or similar surface.*

Informational Note: For protection against corrosion, see 300.6.

##### 312.3 Position in Wall

In walls of concrete, tile, or other noncombustible material, cabinets shall be installed so that the front edge of the cabinet is not set back of the finished surface more than 6 mm ( $\frac{1}{4}$  in.). In walls constructed of wood or other combustible material, cabinets shall be flush with the finished surface or project therefrom.

##### 312.4 Repairing Noncombustible Surfaces

Noncombustible surfaces that are broken or incomplete shall be repaired so there will be no gaps or open spaces greater than 3 mm ( $\frac{1}{8}$  in.) at the edge of the cabinet or cutout box employing a flush-type cover.

Section 312.4 applies to all noncombustible surfaces and is not limited to plaster or drywall types of construction. It provides requirements for cabinets and cutout boxes similar to the outlet box requirements found in 314.21.

### 312.5 Cabinets, Cutout Boxes, and Meter Socket Enclosures

Conductors entering enclosures within the scope of this article shall be protected from abrasion and shall comply with 312.5(A) through (C).

**(A) Openings to Be Closed.** Openings through which conductors enter shall be adequately closed.

**(B) Metal Cabinets, Cutout Boxes, and Meter Socket Enclosures.** Where metal enclosures within the scope of this article are installed with messenger-supported wiring, open wiring on insulators, or concealed knob-and-tube wiring, conductors shall enter through insulating bushings or, in dry locations, through flexible tubing extending from the last insulating support and firmly secured to the enclosure.

**(C) Cables.** Where cable is used, each cable shall be secured to the cabinet, cutout box, or meter socket enclosure.

The main rule of 312.5(C) prohibits the installation of several cables bunched together and run through a knockout or chase nipple. Individual cable clamps or connectors are required to be used with only one cable per clamp or connector, unless the clamp or connector is identified for more than a single cable.

*Exception: Cables with entirely nonmetallic sheaths shall be permitted to enter the top of a surface-mounted enclosure through one or more nonflexible raceways not less than 450 mm (18 in.) and not more than 3.0 m (10 ft) in length, provided all of the following conditions are met:*

- (a) Each cable is fastened within 300 mm (12 in.), measured along the sheath, of the outer end of the raceway.
- (b) The raceway extends directly above the enclosure and does not penetrate a structural ceiling.
- (c) A fitting is provided on each end of the raceway to protect the cable(s) from abrasion and the fittings remain accessible after installation.
- (d) The raceway is sealed or plugged at the outer end using approved means so as to prevent access to the enclosure through the raceway.
- (e) The cable sheath is continuous through the raceway and extends into the enclosure beyond the fitting not less than 6 mm (¼ in.).
- (f) The raceway is fastened at its outer end and at other points in accordance with the applicable article.
- (g) Where installed as conduit or tubing, the allowable cable fill does not exceed that permitted for complete conduit or tubing systems by Table 1 of Chapter 9 of this Code and all applicable notes thereto.

The exception to 312.5(C) allows multiple nonmetallic cables such as Type NM, NMC, NMS, UF, SE, and USE to enter the top of a surface-mounted enclosure through a nonflexible raceway sleeve or nipple. These sleeves or nipples are permitted to be between 18 in. and 10 ft in length. However, if the nipple length exceeds 24 in., the ampacity adjustment factors of 310.15(B)(2) apply.

*Informational Note:* See Table 1 in Chapter 9, including Note 9, for allowable cable fill in circular raceways. See 310.15(B)(3)(a) for required ampacity reductions for multiple cables installed in a common raceway.

### 312.6 Deflection of Conductors

Conductors at terminals or conductors entering or leaving cabinets or cutout boxes and the like shall comply with 312.6(A) through (C).

*Exception: Wire-bending space in enclosures for motor controllers with provisions for one or two wires per terminal shall comply with 430.10(B).*

**(A) Width of Wiring Gutters.** Conductors shall not be deflected within a cabinet or cutout box unless a gutter having a width in accordance with Table 312.6(A) is provided. Conductors in parallel in accordance with 310.10(H) shall be judged on the basis of the number of conductors in parallel.

**(B) Wire-Bending Space at Terminals.** Wire-bending space at each terminal shall be provided in accordance with 312.6(B)(1) or (B)(2).

**(1) Conductors Not Entering or Leaving Opposite Wall.** Table 312.6(A) shall apply where the conductor does not enter or leave the enclosure through the wall opposite its terminal.

**(2) Conductors Entering or Leaving Opposite Wall.** Table 312.6(B) shall apply where the conductor does enter or leave the enclosure through the wall opposite its terminal.

*Exception No. 1: Where the distance between the wall and its terminal is in accordance with Table 312.6(A), a conductor shall be permitted to enter or leave an enclosure through the wall opposite its terminal, provided the conductor enters or leaves the enclosure where the gutter joins an adjacent gutter that has a width that conforms to Table 312.6(B) for the conductor.*

*Exception No. 2: A conductor not larger than 350 kcmil shall be permitted to enter or leave an enclosure containing only a meter socket(s) through the wall opposite its terminal, provided the distance between the terminal and the opposite wall is not less than that specified in Table 312.6(A)*

**TABLE 312.6(A) Minimum Wire-Bending Space at Terminals and Minimum Width of Wiring Gutters**

Wire Size (AWG or kcmil)	Wires per Terminal									
	1		2		3		4		5	
	mm	in.	mm	in.	mm	in.	mm	in.	mm	in.
14–10	Not specified		—	—	—	—	—	—	—	—
8–6	38.1	1½	—	—	—	—	—	—	—	—
4–3	50.8	2	—	—	—	—	—	—	—	—
2	63.5	2½	—	—	—	—	—	—	—	—
1	76.2	3	—	—	—	—	—	—	—	—
1/0–2/0	88.9	3½	127	5	178	7	—	—	—	—
3/0–4/0	102	4	152	6	203	8	—	—	—	—
250	114	4½	152	6	203	8	254	10	—	—
300–350	127	5	203	8	254	10	305	12	—	—
400–500	152	6	203	8	254	10	305	12	356	14
600–700	203	8	254	10	305	12	356	14	406	16
750–900	203	8	305	12	356	14	406	16	457	18
1000–1250	254	10	—	—	—	—	—	—	—	—
1500–2000	305	12	—	—	—	—	—	—	—	—

Note: Bending space at terminals shall be measured in a straight line from the end of the lug or wire connector (in the direction that the wire leaves the terminal) to the wall, barrier, or obstruction.

and the terminal is a lay-in type, where the terminal is either of the following:

- (a) Directed toward the opening in the enclosure and within a 45 degree angle of directly facing the enclosure wall
- (b) Directly facing the enclosure wall and offset not greater than 50 percent of the bending space specified in Table 312.6(A)

Informational Note: *Offset* is the distance measured along the enclosure wall from the axis of the centerline of the terminal to a line passing through the center of the opening in the enclosure.

Section 312.6(B)(2) and Table 312.6(B) provide the requirements for wire-bending space where straight-in wiring or offset (double bends) is employed at terminals. Section 312.6(B)(1) applies only to 90 degree bends.

The notes to Table 312.6(B) permit a reduction in required bending space for removable and lay-in wire terminals. The removable terminal wire connectors can be either the compression type or the setscrew type. However, connectors are required to be of the type intended for a single conductor (single barrel). Removable connectors designed for multiple wires are not permitted to have a reduction in bending space.

To facilitate wiring, a terminal may be placed on the stripped end of the conductor, which has been cut to the proper length. The terminal is crimped or lightly torqued on the wire as intended. The wire is bent and routed to facilitate mounting onto the stud or landing pad for proper connection. All mechanical screws, bolts, and nuts involved should then be torqued to the proper value. See the commentary following the informational note to 110.14 regarding tightening torques.

In accordance with the notes to Tables 312.6(A) and 312.6(B), when Table 312.6(A) is used, bending space is measured in the direction in which the wire leaves the terminal, and when Table 312.6(B) is used, it is measured in a direction perpendicular to the enclosure wall.

A lay-in-type terminal is a pressure wire connector in which part of the connector is removable or swings away so that the stripped end of the conductor can be laid into the fixed portion of the connector. The removable or swing-away portion is then put back in place and the connector tightened down on the conductor.

Exhibit 312.1 applies the rules of 312.6(B)(1), 312.6(B)(2), and Tables 312.6(A) and 312.6(B) to the wiring for a lay-in-type terminal according to the following list, where *T* stands for the dimension to the terminal, and *G* stands for dimension of the gutter.

TABLE 312.6(B) Minimum Wire-Bending Space at Terminals

1500	—	610	24	—	—	—	—	—	—
1750	—	610	24	—	—	—	—	—	—
2000	—	610	24	—	—	—	—	—	—

1. Bending space at terminals shall be measured in a straight line from the end of the lug or wire connector in a direction perpendicular to the enclosure wall.

2. For removable and lay-in wire terminals intended for only one wire, bending space shall be permitted to be reduced by the following number of millimeters (inches):

<sup>a</sup> 12.7 mm (½ in.)

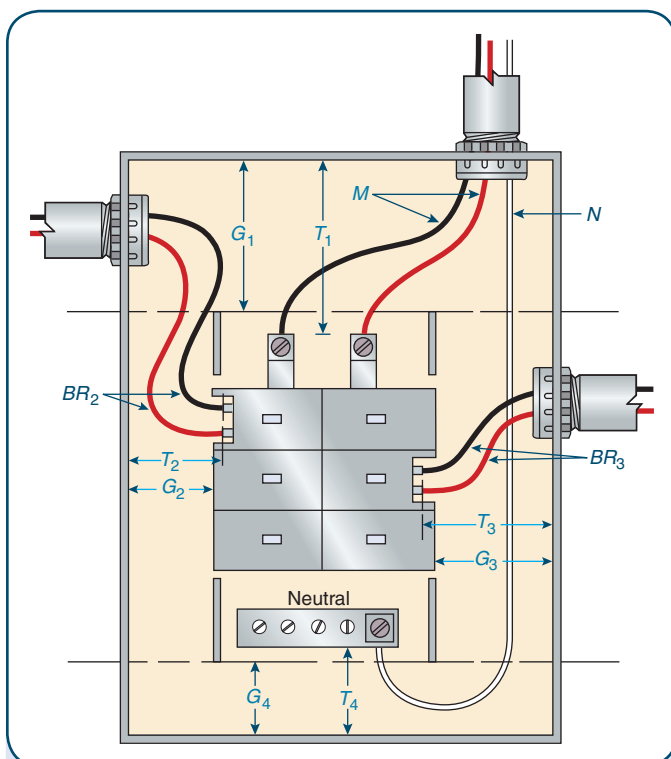

<sup>b</sup> 25.4 mm (1 in.)

<sup>c</sup> 38.1 mm (1½ in.)

<sup>d</sup> 50.8 mm (2 in.)

<sup>e</sup> 76.2 mm (3 in.)

3. This column shall be permitted to determine the required wire-bending space for compact stranded aluminum conductors in sizes up to 1000 kcmil and manufactured using AA-8000 series electrical grade aluminum alloy conductor material in accordance with 310.14.

**EXHIBIT 312.1** Wiring for a lay-in-type terminal to which the list of rules in the commentary following 312.6(B)(2), Exception No. 2 applies.

$T_1$ , 312.6(B)(2): Table 312.6(B) applies for conductors  $M$ .

$T_2$ , 312.6(B)(2): Table 312.6(B) applies for conductors  $BR_2$  unless Exception No. 2 to 312.6(B)(2) applies. This exception allows Table 312.6(A) to apply to  $T_2$  as long as  $BR_2$  enters or leaves the enclosure where gutter  $G_2$  joins gutter  $G_1$  and gutter  $G_1$  has a width conforming to Table 312.6(B) for  $BR_2$ .

$T_3$ , 312.6(B)(2): Table 312.6(B) applies for conductors  $BR_3$ .

$G_4$ , 312.6(A): Table 312.6(A) applies for conductor  $N$ .

Exhibit 312.2 illustrates the conditions under which 312.6(B)(2), Exception No. 2 is applicable. The terminal on the left has an offset not greater than 50 percent of bending

**EXHIBIT 312.2** Conditions under which 312.6(B)(2), Exception No. 2 is applicable.

space, per condition (b) of Exception No. 2. The terminal on the right is within a 45 degree angle of the enclosure, per condition (a) of Exception No. 2. See also Table 430.10(B) and the associated Exhibit 430.1, which shows an example of wire-bending space in enclosures for motor controllers.

**(C) Conductors 4 AWG or Larger.** Installation shall comply with 300.4(G).

### 312.7 Space in Enclosures

Cabinets and cutout boxes shall have sufficient space to accommodate all conductors installed in them without crowding.

### 312.8 Switch and Overcurrent Device Enclosures with Splices, Taps, and Feed-Through Conductors

The wiring space of enclosures for switches or overcurrent devices shall be permitted for conductors feeding through, spliced, or tapping off to other enclosures, switches, or overcurrent devices where all of the following conditions are met:

- (1) The total of all conductors installed at any cross section of the wiring space does not exceed 40 percent of the cross-sectional area of that space.
- (2) The total area of all conductors, splices, and taps installed at any cross section of the wiring space does not exceed 75 percent of the cross-sectional area of that space.
- (3) A warning label is applied to the enclosure that identifies the closest disconnecting means for any feed-through conductors.

This section was revised for the 2011 *Code* to improve usability. Feed-through conductors, splices, and taps are permitted in the wiring space where conditions (1) through (3) are met.

Conditions (1) and (2) are rewritten from the 2008 edition. The total conductor fill in the enclosure must not exceed 40 percent of the cross section of the wiring space in the enclosure and no more than 75 percent if splices or taps are necessary. Condition (3) was added to require a warning label that provides the location of the nearest disconnecting means for any feed-through conductors.

#### Application Example

If an enclosure has a wiring space of 4 in. wide by 3 in. deep, the cross-sectional area is 12 in.<sup>2</sup> Thus, the total conductor fill (see Chapter 9, Table 5 for dimensions of conductors) at any cross section cannot exceed 4.8 in.<sup>2</sup> (40 percent of 12 in.<sup>2</sup>), and the maximum space for conductors and splices or taps at any cross section cannot exceed 9 in.<sup>2</sup> (75 percent of 12 in.<sup>2</sup>).

In general, the best way to avoid overcrowding enclosures is to properly plan and lay out work before installation and use properly sized auxiliary gutters (366.22, 366.56, and 366.58) or junction boxes (314.16 and 314.28). For wiring space in enclosures for motor controllers and disconnecting means, see 430.10 and the associated commentary. See also 110.59 for tunnel installations over 600 volts.

### 312.9 Side or Back Wiring Spaces or Gutters

Cabinets and cutout boxes shall be provided with back-wiring spaces, gutters, or wiring compartments as required by 312.11(C) and (D).

## II. Construction Specifications

### 312.10 Material

Cabinets, cutout boxes, and meter socket enclosures shall comply with 312.10(A) through (C).

**(A) Metal Cabinets and Cutout Boxes.** Metal enclosures within the scope of this article shall be protected both inside and outside against corrosion.

*Informational Note:* For information on protection against corrosion, see 300.6.

**(B) Strength.** The design and construction of enclosures within the scope of this article shall be such as to secure ample strength and rigidity. If constructed of sheet steel, the metal thickness shall not be less than 1.35 mm (0.053 in.) uncoated.

**(C) Nonmetallic Cabinets.** Nonmetallic cabinets shall be listed, or they shall be submitted for approval prior to installation.

### 312.11 Spacing

The spacing within cabinets and cutout boxes shall comply with 312.11(A) through (D).

**(A) General.** Spacing within cabinets and cutout boxes shall be sufficient to provide ample room for the distribution of wires and cables placed in them and for a separation between metal parts of devices and apparatus mounted within them in accordance with (A)(1), (A)(2), and (A)(3).

**(1) Base.** Other than at points of support, there shall be an airspace of at least 1.59 mm (0.0625 in.) between the base of the device and the wall of any metal cabinet or cutout box in which the device is mounted.

**(2) Doors.** There shall be an airspace of at least 25.4 mm (1.00 in.) between any live metal part, including live metal parts of enclosed fuses, and the door.

*Exception:* Where the door is lined with an approved insulating material or is of a thickness of metal not less than 2.36 mm (0.093 in.) uncoated, the airspace shall not be less than 12.7 mm (0.500 in.).

**(3) Live Parts.** There shall be an airspace of at least 12.7 mm (0.500 in.) between the walls, back, gutter partition, if of metal, or door of any cabinet or cutout box and the nearest exposed current-carrying part of devices mounted within the cabinet where the voltage does not exceed 250. This spacing shall be increased to at least 25.4 mm (1.00 in.) for voltages of 251 to 600, nominal.

*Exception:* Where the conditions in 312.11(A)(2), *Exception*, are met, the airspace for nominal voltages from 251 to 600 shall be permitted to be not less than 12.7 mm (0.500 in.).

**(B) Switch Clearance.** Cabinets and cutout boxes shall be deep enough to allow the closing of the doors when 30-ampere branch-circuit panelboard switches are in any position, when combination cutout switches are in any position, or when other single-throw switches are opened as far as their construction permits.

**(C) Wiring Space.** Cabinets and cutout boxes that contain devices or apparatus connected within the cabinet or box to more than eight conductors, including those of branch circuits, meter loops, feeder circuits, power circuits, and similar circuits, but not including the supply circuit or a continuation thereof, shall have back-wiring spaces or one or more side-wiring spaces, side gutters, or wiring compartments.

**(D) Wiring Space — Enclosure.** Side-wiring spaces, side gutters, or side-wiring compartments of cabinets and cutout boxes shall be made tight enclosures by means of covers,

barriers, or partitions extending from the bases of the devices contained in the cabinet, to the door, frame, or sides of the cabinet.

*Exception: Side-wiring spaces, side gutters, and side-wiring compartments of cabinets shall not be required to be made tight enclosures where those side spaces contain only conductors that enter the cabinet directly opposite to the devices where they terminate.*

Partially enclosed back-wiring spaces shall be provided with covers to complete the enclosure. Wiring spaces that are required by 312.11(C) and are exposed when doors are open shall be provided with covers to complete the enclosure. Where adequate space is provided for feed-through conductors and for splices as required in 312.8, additional barriers shall not be required.

## I. Scope and General

### 314.1 Scope

This article covers the installation and use of all boxes and conduit bodies used as outlet, device, junction, or pull boxes, depending on their use, and handhole enclosures. Cast, sheet metal, nonmetallic, and other boxes such as FS, FD, and larger boxes are not classified as conduit bodies. This article also includes installation requirements for fittings used to join raceways and to connect raceways and cables to boxes and conduit bodies.

### 314.2 Round Boxes

Round boxes shall not be used where conduits or connectors requiring the use of locknuts or bushings are to be connected to the side of the box.

Section 314.2 requires the use of rectangular or octagonal boxes having a flat bearing surface at each knockout for locknuts and bushings to ensure effective grounding continuity. Round boxes, however, can be used if the conduit or cable is secured by clamps within the box or if the cable does not need attachment to the box, as permitted by 314.17(C), Exception.

### 314.3 Nonmetallic Boxes

Nonmetallic boxes shall be permitted only with open wiring on insulators, concealed knob-and-tube wiring, cabled wiring methods with entirely nonmetallic sheaths, flexible cords, and nonmetallic raceways.

*Exception No. 1: Where internal bonding means are provided between all entries, nonmetallic boxes shall be permitted to be used with metal raceways or metal-armored cables.*

Exception No. 1 applies to nonmetallic boxes without threaded entries and permits the use of metal raceways and

metal-armored cables with nonmetallic boxes. Internal bonding means must be installed to ensure ground continuity between the metal raceways or metal-armored cables. For the purposes of Exception No. 1, the term *metal-armored cable* includes cables with a metal covering such as mineral-insulated, metal-sheathed cable (Type MI), metal-clad cable (Type MC), and armored cable (Type AC).

*Exception No. 2: Where integral bonding means with a provision for attaching an equipment bonding jumper inside the box are provided between all threaded entries in nonmetallic boxes listed for the purpose, nonmetallic boxes shall be permitted to be used with metal raceways or metal-armored cables.*

Exception No. 2 permits the use of metal raceways and metal-armored cables with listed nonmetallic boxes equipped with threaded entries. An integral bonding means is required to ensure ground continuity between the threaded entries. The requirement for means to attach a bonding jumper accommodates devices or equipment attached to the box. For the purposes of Exception No. 2, the term *metal-armored cable* includes cables with a metal covering such as mineral-insulated, metal-sheathed cable (Type MI), metal-clad cable (Type MC), and armored cable (Type AC).

### 314.4 Metal Boxes

Metal boxes shall be grounded and bonded in accordance with Parts I, IV, V, VI, VII, and X of Article 250 as applicable, except as permitted in 250.112(I).

## II. Installation

### 314.15 Damp or Wet Locations

In damp or wet locations, boxes, conduit bodies, and fittings shall be placed or equipped so as to prevent moisture from entering or accumulating within the box, conduit body, or fitting. Boxes, conduit bodies, and fittings installed in wet locations shall be listed for use in wet locations.

Informational Note No. 1: For boxes in floors, see 314.27(B).

Informational Note No. 2: For protection against corrosion, see 300.6.

Section 314.15 requires protection for boxes, conduit bodies, and fittings installed in wet locations, including exposure to weather. Article 100 defines the term *weatherproof* as “constructed or protected so that exposure to the weather will not interfere with successful operation.” Rainproof,

raintight, or watertight equipment can fulfill the requirements of this definition where varying weather conditions other than wetness, such as snow, ice, dust, or temperature extremes, are not a factor. A weatherhead fitting is considered to be weatherproof because the openings for the conductors are placed in a downward position so that rain or snow cannot enter the fitting.

See the definitions of *location*, *damp* and *location*, *wet* in Article 100, as well as the commentary following the definition of *enclosure*, for further explanation. See also 110.28 and Table 110.28 for enclosure type number selections (e.g., Type 1, Type 3R, and Type 4X).

### 314.16 Number of Conductors in Outlet, Device, and Junction Boxes, and Conduit Bodies

Boxes and conduit bodies shall be of sufficient size to provide free space for all enclosed conductors. In no case shall the volume of the box, as calculated in 314.16(A), be less than the

fill calculation as calculated in 314.16(B). The minimum volume for conduit bodies shall be as calculated in 314.16(C).

The provisions of this section shall not apply to terminal housings supplied with motors or generators.

Informational Note: For volume requirements of motor or generator terminal housings, see 430.12.

Boxes and conduit bodies enclosing conductors 4 AWG or larger shall also comply with the provisions of 314.28.

**(A) Box Volume Calculations.** The volume of a wiring enclosure (box) shall be the total volume of the assembled sections and, where used, the space provided by plaster rings, domed covers, extension rings, and so forth, that are marked with their volume or are made from boxes the dimensions of which are listed in Table 314.16(A).

**(1) Standard Boxes.** The volumes of standard boxes that are not marked with their volume shall be as given in Table 314.16(A).

TABLE 314.16(A) Metal Boxes

Box Trade Size			Minimum Volume		Maximum Number of Conductors* (arranged by AWG size)

\*Where no volume allowances are required by 314.16(B)(2) through (B)(5).

**(2) Other Boxes.** Boxes 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) or less, other than those described in Table 314.16(A), and nonmetallic boxes shall be durably and legibly marked by the manufacturer with their volume. Boxes described in Table 314.16(A) that have a volume larger than is designated in the table shall be permitted to have their volume marked as required by this section.

**(B) Box Fill Calculations.** The volumes in paragraphs 314.16(B)(1) through (B)(5), as applicable, shall be added together. No allowance shall be required for small fittings such as locknuts and bushings.

**(1) Conductor Fill.** Each conductor that originates outside the box and terminates or is spliced within the box shall be counted once, and each conductor that passes through the box without splice or termination shall be counted once. Each loop or coil of unbroken conductor not less than twice the minimum length required for free conductors in 300.14 shall be counted twice. The conductor fill shall be calculated using Table 314.16(B). A conductor, no part of which leaves the box, shall not be counted.

*Exception: An equipment grounding conductor or conductors or not over four fixture wires smaller than 14 AWG, or both, shall be permitted to be omitted from the calculations where they enter a box from a domed luminaire or similar canopy and terminate within that box.*

**(2) Clamp Fill.** Where one or more internal cable clamps, whether factory or field supplied, are present in the box, a single volume allowance in accordance with Table 314.16(B) shall be made based on the largest conductor present in the box. No allowance shall be required for a cable connector with its clamping mechanism outside the box.

**(3) Support Fittings Fill.** Where one or more luminaire studs or hickey are present in the box, a single volume allowance in accordance with Table 314.16(B) shall be made for each type of fitting based on the largest conductor present in the box.

**(4) Device or Equipment Fill.** For each yoke or strap containing one or more devices or equipment, a double volume allowance in accordance with Table 314.16(B) shall be made for each yoke or strap based on the largest conductor connected to a device(s) or equipment supported by that yoke or strap. A device or utilization equipment wider than a single 50 mm (2 in.) device box as described in Table 314.16(A) shall have double volume allowances provided for each gang required for mounting.

**(5) Equipment Grounding Conductor Fill.** Where one or more equipment grounding conductors or equipment bonding jumpers enter a box, a single volume allowance in ac-

**TABLE 314.16(B) Volume Allowance Required per Conductor**

Size of Conductor (AWG)	Free Space Within Box for Each Conductor	
	cm <sup>3</sup>	in. <sup>3</sup>
18	24.6	1.50
16	28.7	1.75
14	32.8	2.00
12	36.9	2.25
10	41.0	2.50
8	49.2	3.00
6	81.9	5.00

cordance with Table 314.16(B) shall be made based on the largest equipment grounding conductor or equipment bonding jumper present in the box. Where an additional set of equipment grounding conductors, as permitted by 250.146(D), is present in the box, an additional volume allowance shall be made based on the largest equipment grounding conductor in the additional set.

Section 314.16 provides the requirements, and identifies the allowances, for the number of conductors permitted to be enclosed within a box. This section requires that the *total box volume* be equal to or greater than the *total box fill*.

The total box volume is determined by adding the individual volumes of the box components. The components include the box itself plus any attachments to it, such as a plaster ring, an extension ring, or a dome cover. The volume of each box component is determined either from the volume marking on the component itself or from the standard volumes listed in Table 314.16(A). If a box is marked with a volume larger than listed in Table 314.16(A), the larger volume can be used instead of the table value.

Adding all the volume allowances for all items contributing to box fill determines the total box fill. The volume allowance for each fill item is based on the volume listed in Table 314.16(B) for the conductor size indicated. Commentary Table 314.1 summarizes the components contributing to box fill.

**Calculation Example 1**

Using the simple method [according to the footnote of Table 314.16(A)], select a standard-sized box for use where all the conductors are the same size and, as shown in Exhibit 314.1, the box does not contain any cable clamps, support fittings, devices, or equipment grounding conductors.

**Solution**

To determine the number of conductors permitted in the box, which is a standard 4 in. × 1½ in. square box (21.0 in.<sup>3</sup>),

**COMMENTARY TABLE 314.1** Summary of Items Contributing to Box Fill

Items Contained Within Box	Volume Allowance	Based on [see Table 314.16(B)]
Conductors that originate outside box	One for each conductor	Actual conductor size
Conductors that pass through box without splice or connection (less than 12 in. in total length)	One for each conductor	Actual conductor size
Conductors 12 in. or greater that are looped (or coiled) and unbroken (see 300.14 for exact measurement)	Two for a single (entire) unbroken conductor	Actual conductor size
Conductors that originate within box and do not leave box	None (these conductors not counted)	n.a.
Fixture wires [per 314.16(B)(1), Exception]	None (these conductors not counted)	n.a.
Internal cable clamps (one or more)	One only	Largest-sized conductor present
Support fittings (such as luminaire studs or hickey)	One for each type of support fitting	Largest-sized conductor present
Devices (such as receptacles, switches) or utilization equipment (such as timers, dimmers, AFCI receptacles, GFCI receptacles, TVSS receptacles)	Two for each yoke or mounting strap	Largest-sized conductor connected to device or utilization equipment
Equipment grounding conductor (one or more)	One only	Largest equipment grounding conductor present
Isolated equipment grounding conductor (one or more) [see 250.146(D)]	One only	Largest isolated and insulated equipment grounding conductor present

n.a. = not applicable.

Standard 4 in. x 1½ in. square box (21.0 in.<sup>3</sup>)

**EXHIBIT 314.1** Example 1: A standard-sized square box containing no fittings or devices, such as luminaire studs, cable clamps, switches, receptacles, or equipment grounding conductors.

count the conductors in the box and compare the total to the maximum number of conductors permitted by Table 314.16(A). Each unspliced conductor running through the box is counted as one conductor, and each other conductor is counted as one conductor. Therefore, the total conductor

count for this box is nine conductors. Table 314.16(A) indicates that the maximum fill for this box is nine 12 AWG conductors, so the box is adequately sized.

### Calculation Example 2

The standard method for determining adequate box size first calculates the total box volume and then subtracts the total box fill to ensure compliance. Using this method, determine whether the box in Exhibit 314.2 is adequately sized.

#### Solution

For a standard 3 in. x 2 in. x 3½ in. device box, Table 314.16(A) shows the minimum permitted box volume to be 18 in.<sup>3</sup> and allows up to a maximum of nine 14 AWG conductors. The box fill for this situation as given in Commentary Table 314.2 is 16 in.<sup>3</sup>. Because the total box fill of 16 in.<sup>3</sup> is less than the 18 in.<sup>3</sup> total box volume permitted, the box is adequately sized.

### Calculation Example 3

Using the standard method, determine the adequacy of the device box illustrated in Exhibit 314.3, where two standard-sized 3 in. x 2 in. x 3½ in. device boxes have been ganged to form a single box.

#### Solution

Table 314.16(A) shows that the permitted box volume for a single box is 18 in.<sup>3</sup>. Thus, the total box volume for the

**EXHIBIT 314.2** Example 2: A standard-sized device box containing a device and conductors requiring deductions in accordance with 314.16.

ganged box is 36 in.<sup>3</sup> (2 × 18 in.<sup>3</sup>). The total box fill, based on Table 314.16(B), is determined as given in Commentary Table 314.3. With only 26 in.<sup>3</sup> of the 36 in.<sup>3</sup> filled, the box is adequately sized.

(C) Conduit Bodies.

**(1) General.** Conduit bodies enclosing 6 AWG conductors or smaller, other than short-radius conduit bodies as described in 314.16(C)(2), shall have a cross-sectional area not less than twice the cross-sectional area of the largest conduit or tubing to which they can be attached. The maximum number of conductors permitted shall be the maximum number permitted by Table 1 of Chapter 9 for the conduit or tubing to which it is attached.

**(2) With Splices, Taps, or Devices.** Only those conduit bodies that are durably and legibly marked by the manufacturer with their volume shall be permitted to contain splices, taps, or devices. The maximum number of conductors shall

**EXHIBIT 314.3** Example 3: Two standard gangable device boxes containing conductors of different sizes.

be calculated in accordance with 314.16(B). Conduit bodies shall be supported in a rigid and secure manner.

Conduit bodies other than the short-radius type are permitted by 314.16(C) to contain splices or taps, provided the conduit bodies are marked with their cubic inch capacity, as illustrated in Exhibit 314.4. Such conduit bodies are required to have a cross-sectional area not less than twice that of the conduit to which they are attached and are not permitted to contain more conductors than the attached raceway. The volume requirements for splicing or tapping are provided in 314.16(C)(2).

Conduit bodies must be rigidly supported. See the exception to 314.23(E), and Exception No. 1 to 314.23(F), which permits the raceway to support the conduit body, provided the conduit body is not larger than the attached raceway. See 314.28 for requirements that apply to conduit bodies used as pull and junction boxes.

**COMMENTARY TABLE 314.2** Total Box Fill for Example 2

Items Contained Within Box		Volume Allowance	Unit Volume Based on Table 314.16(B) (in. <sup>3</sup> )	Total Box Fill (in. <sup>3</sup> )
4 conductors	4 volume allowances for 14 AWG conductors		2.00	8.00
1 clamp	1 volume allowance (based on 14 AWG conductors)		2.00	2.00
1 device	2 volume allowances (based on 14 AWG conductors)		2.00	4.00
Equipment grounding conductors (all)	1 volume allowance (based on 14 AWG conductors)		2.00	2.00
Total				16.00

**COMMENTARY TABLE 314.3** Total Box Fill for Example 3

Items Contained Within Box	Volume Allowance	Unit Volume Based on Table 314.16(B) (in. <sup>3</sup> )	Total Box Fill (in. <sup>3</sup> )
6 conductors	2 volume allowances for 14 AWG conductors	2.00	4.00
	4 volume allowances for 12 AWG conductors	2.25	9.00
2 clamps	1 volume allowance (based on 12 AWG conductors)	2.25	2.25
2 devices	2 volume allowances (based on 14 AWG conductors)	2.00	4.00
	2 volume allowances (based on 12 AWG conductors)	2.25	4.50
Equipment grounding conductors (all)	1 volume allowance (based on 12 AWG conductors)	2.25	2.25
Total			26.00

**EXHIBIT 314.4** An example of splices in a raceway-supported conduit body permitted by 314.16(C)(2).

**(3) Short Radius Conduit Bodies.** Conduit bodies such as capped elbows and service-entrance elbows that enclose conductors 6 AWG or smaller, and are only intended to enable the installation of the raceway and the contained conductors, shall not contain splices, taps, or devices and shall be of sufficient size to provide free space for all conductors enclosed in the conduit body.

This section was relocated here for the 2011 *Code*. The requirements were formerly in 314.5.

### 314.17 Conductors Entering Boxes, Conduit Bodies, or Fittings

Conductors entering boxes, conduit bodies, or fittings shall be protected from abrasion and shall comply with 314.17(A) through (D).

**(A) Openings to Be Closed.** Openings through which conductors enter shall be adequately closed.

**(B) Metal Boxes and Conduit Bodies.** Where metal boxes or conduit bodies are installed with messenger-supported wiring, open wiring on insulators, or concealed knob-and-tube wiring, conductors shall enter through insulating bushings or, in dry locations, through flexible tubing extending

from the last insulating support to not less than 6 mm (¼ in.) inside the box and beyond any cable clamps. Except as provided in 300.15(C), the wiring shall be firmly secured to the box or conduit body. Where raceway or cable is installed with metal boxes or conduit bodies, the raceway or cable shall be secured to such boxes and conduit bodies.

**(C) Nonmetallic Boxes and Conduit Bodies.** Nonmetallic boxes and conduit bodies shall be suitable for the lowest temperature-rated conductor entering the box. Where nonmetallic boxes and conduit bodies are used with messenger-supported wiring, open wiring on insulators, or concealed knob-and-tube wiring, the conductors shall enter the box through individual holes. Where flexible tubing is used to enclose the conductors, the tubing shall extend from the last insulating support to not less than 6 mm (¼ in.) inside the box and beyond any cable clamp. Where nonmetallic-sheathed cable or multiconductor Type UF cable is used, the sheath shall extend not less than 6 mm (¼ in.) inside the box and beyond any cable clamp. In all instances, all permitted wiring methods shall be secured to the boxes.

Standard nonmetallic boxes are permitted for use with 90°C insulated conductors. A nonmetallic box used for splicing a conductor of a higher temperature rating to a conductor of a lower temperature rating is required to be identified as suitable for the temperature rating of the lower-rated conductor because the maximum temperature permitted will be that of the lower-rated conductor. The intent is to avoid the necessity of giving a high temperature rating to boxes in a normal temperature location simply because high-temperature conductors enter the box from or exit to a high-temperature location. However, where insulated conductors rated at higher temperatures are necessary in a high-temperature environment, the box is required to be suitably identified by a marking on the box or in the listing of the box to comply with 110.3(B).

*Exception: Where nonmetallic-sheathed cable or multiconductor Type UF cable is used with single gang boxes not larger than a nominal size 57 mm × 100 mm (2¼ in. × 4 in.) mounted in walls or ceilings, and where the cable is fastened within 200 mm (8 in.) of the box measured along the sheath and where the sheath extends through a cable knockout not less than 6 mm (¼ in.), securing the cable to the box shall not be required. Multiple cable entries shall be permitted in a single cable knockout opening.*

The exception to 314.17(C) identifies the conditions under which securing the cable to the box is not required. Exhibit 314.5 is an example of an installation that complies with the exception.

**EXHIBIT 314.5** Installation of a single gang outlet box permitted by the exception to 314.17(C), provided the cables are securely fastened within 8 in. of the box. (Courtesy of the International Association of Electrical Inspectors)

**(D) Conductors 4 AWG or Larger.** Installation shall comply with 300.4(G).

Informational Note: See 110.12(A) for requirements on closing unused cable and raceway knockout openings.

### 314.19 Boxes Enclosing Flush Devices

Boxes used to enclose flush devices shall be of such design that the devices will be completely enclosed on back and sides and substantial support for the devices will be provided. Screws for supporting the box shall not be used in attachment of the device contained therein.

### 314.20 In Wall or Ceiling

In walls or ceilings with a surface of concrete, tile, gypsum, plaster, or other noncombustible material, boxes employing

a flush-type cover or faceplate shall be installed so that the front edge of the box, plaster ring, extension ring, or listed extender will not be set back of the finished surface more than 6 mm (¼ in.).

In walls and ceilings constructed of wood or other combustible surface material, boxes, plaster rings, extension rings, or listed extenders shall be flush with the finished surface or project therefrom.

The requirements of 314.20 apply only to the construction of the surface of the wall or ceiling, not to the structure or subsurface of the wall or ceiling. Therefore, a wall constructed of wood but sheathed with an outer layer of gypsum board is permitted to contain boxes set back or recessed not more than ¼ in. Using an opposite example, a wall constructed of metal studs but finished with wood panels requires that contained outlet boxes be mounted flush with the combustible finish.

### 314.21 Repairing Noncombustible Surfaces

Noncombustible surfaces that are broken or incomplete around boxes employing a flush-type cover or faceplate shall be repaired so there will be no gaps or open spaces greater than 3 mm (⅛ in.) at the edge of the box.

This section was revised for the 2011 *Code*. The requirement for repairing surfaces of wall in which junction boxes or outlet boxes are installed is the same as required for cabinets, cutout boxes, and meter socket enclosures.

### 314.22 Surface Extensions

Surface extensions shall be made by mounting and mechanically securing an extension ring over the box. Equipment grounding shall be in accordance with Part VI of Article 250.

*Exception: A surface extension shall be permitted to be made from the cover of a box where the cover is designed so it is unlikely to fall off or be removed if its securing means becomes loose. The wiring method shall be flexible for a length sufficient to permit removal of the cover and provide access to the box interior, and arranged so that any grounding continuity is independent of the connection between the box and cover.*

The exception to 314.22 permits a flexible surface extension to be made from a flush-mounted outlet box, as illustrated in Exhibit 314.6. This technique requires the use of a cover that will not fall off if the securing screws become loose. Grounding continuity must not rely on the means to secure the box to the cover.

**EXHIBIT 314.6** An example of a flexible surface extension made from the cover of a flush-mounted outlet box according to the exception permitted by 314.22.

### 314.23 Supports

Enclosures within the scope of this article shall be supported in accordance with one or more of the provisions in 314.23(A) through (H).

**(A) Surface Mounting.** An enclosure mounted on a building or other surface shall be rigidly and securely fastened in place. If the surface does not provide rigid and secure support, additional support in accordance with other provisions of this section shall be provided.

**(B) Structural Mounting.** An enclosure supported from a structural member of a building or from grade shall be rigidly supported either directly or by using a metal, polymeric, or wood brace.

**(1) Nails and Screws.** Nails and screws, where used as a fastening means, shall be attached by using brackets on the outside of the enclosure, or they shall pass through the interior within 6 mm ( $\frac{1}{4}$  in.) of the back or ends of the enclosure. Screws shall not be permitted to pass through the box unless exposed threads in the box are protected using approved means to avoid abrasion of conductor insulation.

The intent of the requirements in 314.23(B)(1) is to prevent nails and screws from interfering with the installation of devices. Permitting nails inside the box within  $\frac{1}{4}$  in. of the ends reduces splitting of the smaller wooden studs used in some frame-type construction. However, splitting sometimes occurs where nails are within  $\frac{1}{4}$  in. of the back of the box.

The last sentence points out that the coarse screw threads found on most screws used for mounting boxes present a severe abrasion hazard to conductor insulation when the threads are left exposed inside a box.

**(2) Braces.** Metal braces shall be protected against corrosion and formed from metal that is not less than 0.51 mm (0.020 in.) thick uncoated. Wood braces shall have a cross section not less than nominal 25 mm  $\times$  50 mm (1 in.  $\times$  2 in.). Wood braces in wet locations shall be treated for the conditions. Polymeric braces shall be identified as being suitable for the use.

**(C) Mounting in Finished Surfaces.** An enclosure mounted in a finished surface shall be rigidly secured thereto by clamps, anchors, or fittings identified for the application.

Where structural members are lacking or where boxes are cut into existing walls, boxes are permitted to be secured by clamps or anchors. Exhibit 314.7 shows several examples of “old work” boxes that are designed to be installed into a finished wall or ceiling. The three nonmetallic boxes have mounting tabs that secure to the back of the finished surface as the screws on the front of the box are tightened. The metal boxes have mounting tabs that are designed to accept screws that secure the box to a surface such as wood paneling or wainscoting. The metal brackets shown can be used to secure a box to a wall surface such as gypsum wall board.

**EXHIBIT 314.7** Metal and nonmetallic outlet boxes designed for mounting in finished wall and ceiling surfaces per 314.23(C).

**(D) Suspended Ceilings.** An enclosure mounted to structural or supporting elements of a suspended ceiling shall be not more than 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) in size and shall be securely fastened in place in accordance with either (D)(1) or (D)(2).

**(1) Framing Members.** An enclosure shall be fastened to the framing members by mechanical means such as bolts,

screws, or rivets, or by the use of clips or other securing means identified for use with the type of ceiling framing member(s) and enclosure(s) employed. The framing members shall be adequately supported and securely fastened to each other and to the building structure.

**(2) Support Wires.** The installation shall comply with the provisions of 300.11(A). The enclosure shall be secured, using methods identified for the purpose, to ceiling support wire(s), including any additional support wire(s) installed for that purpose. Support wire(s) used for enclosure support shall be fastened at each end so as to be taut within the ceiling cavity.

**(E) Raceway Supported Enclosure, Without Devices, Luminaires, or Lampholders.** An enclosure that does not contain a device(s) other than splicing devices or support a luminaire(s), lampholder, or other equipment and is supported by entering raceways shall not exceed 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) in size. It shall have threaded entries or have hubs identified for the purpose. It shall be supported by two or more conduits threaded wrenchtight into the enclosure or hubs. Each conduit shall be secured within 900 mm (3 ft) of the enclosure, or within 450 mm (18 in.) of the enclosure if all conduit entries are on the same side.

Boxes are not permitted to be supported by rigid raceways using locknuts and bushings. Enclosures without devices or luminaires are considered to be adequately supported, provided the conduit is connected to the enclosure by threaded hubs and the threaded conduits enter the box on two or more sides and are supported within 3 ft of the enclosure. A box is not permitted to be supported by a single raceway.

*Exception: The following wiring methods shall be permitted to support a conduit body of any size, including a conduit body constructed with only one conduit entry, if the trade size of the conduit body is not larger than the largest trade size of the conduit or tubing:*

- (1) Intermediate metal conduit, Type IMC
- (2) Rigid metal conduit, Type RMC
- (3) Rigid polyvinyl chloride conduit, Type PVC
- (4) Reinforced thermosetting resin conduit, Type RTRC
- (5) Electrical metallic tubing, Type EMT

This exception was revised for the 2011 Code to provide a list of the acceptable wiring methods that the exception applies to.

**(F) Raceway-Supported Enclosures, with Devices, Luminaires, or Lampholders.** An enclosure that contains a

device(s), other than splicing devices, or supports a luminaire(s), lampholder, or other equipment and is supported by entering raceways shall not exceed 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) in size. It shall have threaded entries or have hubs identified for the purpose. It shall be supported by two or more conduits threaded wrenchtight into the enclosure or hubs. Each conduit shall be secured within 450 mm (18 in.) of the enclosure.

Section 314.23(F) requires that conduit be supported within 18 in. of the enclosure if the enclosure contains devices (other than splicing devices) or luminaires.

*Exception No. 1: Rigid metal or intermediate metal conduit shall be permitted to support a conduit body of any size, including a conduit body constructed with only one conduit entry, provided the trade size of the conduit body is not larger than the largest trade size of the conduit.*

*Exception No. 2: An unbroken length(s) of rigid or intermediate metal conduit shall be permitted to support a box used for luminaire or lampholder support, or to support a wiring enclosure that is an integral part of a luminaire and used in lieu of a box in accordance with 300.15(B), where all of the following conditions are met:*

- (a) The conduit is securely fastened at a point so that the length of conduit beyond the last point of conduit support does not exceed 900 mm (3 ft).
- (b) The unbroken conduit length before the last point of conduit support is 300 mm (12 in.) or greater, and that portion of the conduit is securely fastened at some point not less than 300 mm (12 in.) from its last point of support.
- (c) Where accessible to unqualified persons, the luminaire or lampholder, measured to its lowest point, is at least 2.5 m (8 ft) above grade or standing area and at least 900 mm (3 ft) measured horizontally to the 2.5 m (8 ft) elevation from windows, doors, porches, fire escapes, or similar locations.
- (d) A luminaire supported by a single conduit does not exceed 300 mm (12 in.) in any direction from the point of conduit entry.
- (e) The weight supported by any single conduit does not exceed 9 kg (20 lb).
- (f) At the luminaire or lampholder end, the conduit(s) is threaded wrenchtight into the box, conduit body, or integral wiring enclosure, or into hubs identified for the purpose. Where a box or conduit body is used for support, the luminaire shall be secured directly to the box or conduit body, or through a threaded conduit nipple not over 75 mm (3 in.) long.

**(G) Enclosures in Concrete or Masonry.** An enclosure supported by embedment shall be identified as suitably pro-

protected from corrosion and securely embedded in concrete or masonry.

Boxes are permitted to be embedded in masonry or concrete, provided they are rigid and secure. Corrosion protection is required due to the corrosive effects of concrete. Exhibit 314.8 shows a mud box installed in a concrete ceiling. Additional support is not required.

**EXHIBIT 314.8** A mud box installed in a concrete ceiling in compliance with 314.23(G).

**(H) Pendant Boxes.** An enclosure supported by a pendant shall comply with 314.23(H)(1) or (H)(2).

**(1) Flexible Cord.** A box shall be supported from a multi-conductor cord or cable in an approved manner that protects the conductors against strain, such as a strain-relief connector threaded into a box with a hub.

**(2) Conduit.** A box supporting lampholders or luminaires, or wiring enclosures within luminaires used in lieu of boxes in accordance with 300.15(B), shall be supported by rigid or intermediate metal conduit stems. For stems longer than 450 mm (18 in.), the stems shall be connected to the wiring system with flexible fittings suitable for the location. At the luminaire end, the conduit(s) shall be threaded wrenchtight into the box or wiring enclosure, or into hubs identified for the purpose.

Where supported by only a single conduit, the threaded joints shall be prevented from loosening by the use of set-screws or other effective means, or the luminaire, at any point, shall be at least 2.5 m (8 ft) above grade or standing area and at least 900 mm (3 ft) measured horizontally to the 2.5 m (8 ft) elevation from windows, doors, porches, fire escapes, or similar locations. A luminaire supported by a single conduit shall not exceed 300 mm (12 in.) in any horizontal direction from the point of conduit entry.

### 314.24 Depth of Boxes

Outlet and device boxes shall have sufficient depth to allow equipment installed within them to be mounted properly

and without likelihood of damage to conductors within the box.

**(A) Outlet Boxes Without Enclosed Devices or Utilization Equipment.** Outlet boxes that do not enclose devices or utilization equipment shall have a minimum internal depth of 12.7 mm ( $\frac{1}{2}$  in.).

**(B) Outlet and Device Boxes with Enclosed Devices or Utilization Equipment.** Outlet and device boxes that enclose devices or utilization equipment shall have a minimum internal depth that accommodates the rearward projection of the equipment and the size of the conductors that supply the equipment. The internal depth shall include, where used, that of any extension boxes, plaster rings, or raised covers. The internal depth shall comply with all applicable provisions of (B)(1) through (B)(5).

The use of a shallow box might become necessary because of old work or existing construction where, for example, very shallow partitions, structural members very close to finish surfaces, plumbing pipes, or ductwork is encountered within the partition. In addition to meeting minimum depth requirements, the box selection must be based on its having sufficient cubic-inch capacity.

**(1) Large Equipment.** Boxes that enclose devices or utilization equipment that projects more than 48 mm ( $1\frac{7}{8}$  in.) rearward from the mounting plane of the box shall have a depth that is not less than the depth of the equipment plus 6 mm ( $\frac{1}{4}$  in.).

**(2) Conductors Larger Than 4 AWG.** Boxes that enclose devices or utilization equipment supplied by conductors larger than 4 AWG shall be identified for their specific function.

*Exception to (2): Devices or utilization equipment supplied by conductors larger than 4 AWG shall be permitted to be mounted on or in junction and pull boxes larger than 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) if the spacing at the terminals meets the requirements of 312.6.*

**(3) Conductors 8, 6, or 4 AWG.** Boxes that enclose devices or utilization equipment supplied by 8, 6, or 4 AWG conductors shall have an internal depth that is not less than 52.4 mm ( $2\frac{1}{16}$  in.).

**(4) Conductors 12 or 10 AWG.** Boxes that enclose devices or utilization equipment supplied by 12 or 10 AWG conductors shall have an internal depth that is not less than 30.2 mm ( $1\frac{3}{16}$  in.). Where the equipment projects rearward from the mounting plane of the box by more than 25 mm

(1 in.), the box shall have a depth not less than that of the equipment plus 6 mm ( $\frac{1}{4}$  in.).

**(5) Conductors 14 AWG and Smaller.** Boxes that enclose devices or utilization equipment supplied by 14 AWG or smaller conductors shall have a depth that is not less than 23.8 mm ( $\frac{15}{16}$  in.).

Section 314.24(B)(5) provides the minimum depth requirement for boxes that enclose devices or utilization equipment. The intent is to prevent damage to conductors that can occur where there is insufficient clearance from the device or utilization equipment to the back of the box. Where clearance is insufficient, conductors are often pinched or the insulation is damaged as the device or utilization equipment is pushed into the box.

Article 100 defines *utilization equipment* as equipment that uses electric energy for electronic, electromechanical, chemical, heating, lighting, or similar purposes. Examples of utilization equipment often located within an outlet or device box include common items such as buzzers, speakers, timers, motion detectors, alarms, and video and audio surveillance equipment. Typically, minimum box dimensions are included in product installation instructions for listed utilization equipment.

*Exception to (1) through (5): Devices or utilization equipment that is listed to be installed with specified boxes shall be permitted.*

### 314.25 Covers and Canopies

In completed installations, each box shall have a cover, faceplate, lampholder, or luminaire canopy, except where the installation complies with 410.24(B).

**(A) Nonmetallic or Metal Covers and Plates.** Nonmetallic or metal covers and plates shall be permitted. Where metal covers or plates are used, they shall comply with the grounding requirements of 250.110.

**Informational Note:** For additional grounding requirements, see 410.42 for metal luminaire canopies, and 404.12 and 406.6(B) for metal faceplates.

**(B) Exposed Combustible Wall or Ceiling Finish.** Where a luminaire canopy or pan is used, any combustible wall or ceiling finish exposed between the edge of the canopy or pan and the outlet box shall be covered with noncombustible material.

Because heat from a short circuit, from a ground fault, or due to overlampping could create a fire hazard within a lumi-

naire canopy or pan, any exposed combustible wall or ceiling space between the edge of the outlet box and the perimeter of the luminaire is required by 314.25(B) to be covered with noncombustible material. The noncombustible material need not be metal. Glass fiber pads, commonly provided as thermal barriers within the ceiling pan of luminaires, can be used to meet this requirement. Where the wall or ceiling finish is concrete, tile, gypsum, plaster, or other noncombustible material, the requirements of this section do not apply. Section 314.20 contains requirements for flush-mounted boxes and boxes “set back” from finish surfaces.

**(C) Flexible Cord Pendants.** Covers of outlet boxes and conduit bodies having holes through which flexible cord pendants pass shall be provided with bushings designed for the purpose or shall have smooth, well-rounded surfaces on which the cords may bear. So-called hard rubber or composition bushings shall not be used.

### 314.27 Outlet Boxes

**(A) Boxes at Luminaire or Lampholder Outlets.** Outlet boxes or fittings designed for the support of luminaires and lampholders, and installed as required by 314.23, shall be permitted to support a luminaire or lampholder.

Section 314.27(A) provides the minimum requirement for luminaire support for wall and ceiling installations. Outlet boxes “designed for the support of luminaires” refers to an outlet box that is designed to adequately support a luminaire weighing up to 50 lb. If the box is designed to support other than 50 lb, the maximum design weight must be marked on the inside of the box.

**(1) Wall Outlets.** Boxes used at luminaire or lampholder outlets in a wall shall be marked on the interior of the box to indicate the maximum weight of the luminaire that is permitted to be supported by the box in the wall, if other than 23 kg (50 lb).

*Exception: A wall-mounted luminaire or lampholder weighing not more than 3 kg (6 lb) shall be permitted to be supported on other boxes or plaster rings that are secured to other boxes, provided the luminaire or its supporting yoke, or the lampholder, is secured to the box with no fewer than two No. 6 or larger screws.*

The exception to 314.27(A)(1) permits luminaires such as wall-bracket types or sconces weighing less than 6 lb to be supported by a device box using No. 6 or larger screws. Device boxes designed for the mounting of snap switches,

receptacles, and other devices usually have 6-32 screws (No. 6 screws with 32 threads per inch). Generally, device boxes are not suitable for supporting other than lightweight wall-mounted luminaires.

**(2) Ceiling Outlets.** At every outlet used exclusively for lighting, the box shall be designed or installed so that a luminaire or lampholder may be attached. Boxes shall be required to support a luminaire weighing a minimum of 23 kg (50 lb). A luminaire that weighs more than 23 kg (50 lb) shall be supported independently of the outlet box, unless the outlet box is listed and marked for the maximum weight to be supported.

Regardless of whether a luminaire is attached to an outlet box or is supported independently of the outlet box, care should be taken to securely fasten the supporting means of the luminaire. Boxes designed to support luminaires weighing more than 50 lb must be listed and marked with the maximum weight.

**(B) Floor Boxes.** Boxes listed specifically for this application shall be used for receptacles located in the floor.

*Exception: Where the authority having jurisdiction judges them free from likely exposure to physical damage, moisture, and dirt, boxes located in elevated floors of show windows and similar locations shall be permitted to be other than those listed for floor applications. Receptacles and covers shall be listed as an assembly for this type of location.*

**(C) Boxes at Ceiling-Suspended (Paddle) Fan Outlets.** Outlet boxes or outlet box systems used as the sole support of a ceiling-suspended (paddle) fan shall be listed, shall be marked by their manufacturer as suitable for this purpose, and shall not support ceiling-suspended (paddle) fans that weigh more than 32 kg (70 lb). For outlet boxes or outlet box systems designed to support ceiling-suspended (paddle) fans that weigh more than 16 kg (35 lb), the required marking shall include the maximum weight to be supported.

Where spare, separately switched, ungrounded conductors are provided to a ceiling mounted outlet box, in a location acceptable for a ceiling-suspended (paddle) fan in single or multi-family dwellings, the outlet box or outlet box system shall be listed for sole support of a ceiling-suspended (paddle) fan.

Outlet boxes specifically listed to adequately support ceiling-mounted paddle fans are available, as are several

alternative and retrofit methods that can provide suitable support for a paddle fan. Exhibit 314.9 illustrates two methods to support a fan from an outlet box that is listed for fan support. For a detailed view of an outlet box for a fan where the box does not serve as the sole support, see Exhibit 422.2. This section was revised for the 2011 Code. In new residential construction, it has become common to provide a wall-mounted switch with wiring for paddle fans to ceiling-mounted outlet boxes, even where paddle fans are not provided. This allows a paddle fan to be installed sometime in the future. This section now requires such installations to have an outlet box or outlet box system that is listed for the sole support of a fan.

**EXHIBIT 314.9** Two methods of supporting a ceiling fan from a listed outlet box. (Top) A listed outlet box used as the sole support of a ceiling-suspended (paddle) fan according to 314.27(C). Note the two clamps on the perimeter of the box that will support a fixture. (Courtesy of the International Association of Electrical Inspectors). (Bottom) Supporting a ceiling-suspended (paddle) fan (35 lb or less) with a box identified for such use. (Courtesy of Hubbell RACO).

**(D) Utilization Equipment.** Boxes used for the support of utilization equipment other than ceiling-suspended (paddle) fans shall meet the requirements of 314.27(A) for the support of a luminaire that is the same size and weight.

*Exception: Utilization equipment weighing not more than 3 kg (6 lb) shall be permitted to be supported on other boxes or plaster rings that are secured to other boxes, provided the equipment or its supporting yoke is secured to the box with no fewer than two No. 6 or larger screws.*

### 314.28 Pull and Junction Boxes and Conduit Bodies

Boxes and conduit bodies used as pull or junction boxes shall comply with 314.28(A) through (E).

*Exception: Terminal housings supplied with motors shall comply with the provisions of 430.12.*

**(A) Minimum Size.** For raceways containing conductors of 4 AWG or larger that are required to be insulated, and for cables containing conductors of 4 AWG or larger, the minimum dimensions of pull or junction boxes installed in a raceway or cable run shall comply with (A)(1) through (A)(3). Where an enclosure dimension is to be calculated based on the diameter of entering raceways, the diameter shall be the metric designator (trade size) expressed in the units of measurement employed.

**(1) Straight Pulls.** In straight pulls, the length of the box or conduit body shall not be less than eight times the metric designator (trade size) of the largest raceway.

Section 314.28(A)(1) applies to minimum dimensions of pull and junction boxes or conduit bodies used with raceways or cables containing conductors 4 AWG or larger. For straight pulls, for example, trade size 2 conduit containing four 4/0 AWG, Type THHW conductors (see Informative Annex C, Table C.8) requires a 16-in.-long pull box ( $8 \times 2 \text{ in.} = 16 \text{ in.}$ ). However, although 16 in. is the required minimum length, a longer pull box may be desired for maximum ease in handling this size conductor.

The six times rule of 314.28(A)(2) applies to straight-through conduit entries if the conductors are spliced as part of the straight-through wiring. Adjusting the previous example of trade size 2 conduit containing four 4/0 AWG, Type THHW conductors, provided the conductors were spliced within the enclosure, the required pull box dimension could be reduced to a 12-in.-long pull box ( $6 \times 2 \text{ in.} = 12 \text{ in.}$ ).

Section 314.28(A) addresses raceways or cables that contain conductors 4 AWG or larger and are required to be insulated. One conductor that is not required to be insulated is a grounding electrode conductor. So, where a grounding

electrode conductor is installed as the sole conductor within a raceway, conduit bodies used as part of that raceway system are not required to comply with enclosure dimensions in 314.28(A).

**(2) Angle or U Pulls, or Splices.** Where splices or where angle or U pulls are made, the distance between each raceway entry inside the box or conduit body and the opposite wall of the box or conduit body shall not be less than six times the metric designator (trade size) of the largest raceway in a row. This distance shall be increased for additional entries by the amount of the sum of the diameters of all other raceway entries in the same row on the same wall of the box. Each row shall be calculated individually, and the single row that provides the maximum distance shall be used.

*Exception: Where a raceway or cable entry is in the wall of a box or conduit body opposite a removable cover, the distance from that wall to the cover shall be permitted to comply with the distance required for one wire per terminal in Table 312.6(A).*

The distance between raceway entries enclosing the same conductor shall not be less than six times the metric designator (trade size) of the larger raceway.

When transposing cable size into raceway size in 314.28(A)(1) and (A)(2), the minimum metric designator (trade size) raceway required for the number and size of conductors in the cable shall be used.

Examples of calculations required by 314.28(A)(2) are shown in Exhibits 314.10 and 314.11. As Exhibit 314.10 illustrates, where splices, angle pulls, or U pulls are made, the distance between each raceway entry inside the box and the opposite wall of the box must not be less than six times the trade diameter of the largest raceway, plus the distance for additional raceway entries. This additional distance is calculated by adding the diameters of the other raceway entries in one row on the same side of the box. Exhibit 314.11 shows that raceway entries enclosing the same conductor are required to have a minimum separation between them. The intent is to provide adequate space for the conductor to make the bend.

**(3) Smaller Dimensions.** Boxes or conduit bodies of dimensions less than those required in 314.28(A)(1) and (A)(2) shall be permitted for installations of combinations of conductors that are less than the maximum conduit or tubing fill (of conduits or tubing being used) permitted by Table 1 of Chapter 9, provided the box or conduit body has been listed for, and is permanently marked with, the maximum number and maximum size of conductors permitted.

**EXHIBIT 314.10** An example showing calculations required by 314.28(A)(2) for splices, angle pulls, or U pulls.

**EXHIBIT 314.11** An example showing calculations required by 314.28(A)(2) for raceways enclosing the same conductor.

**(B) Conductors in Pull or Junction Boxes.** In pull boxes or junction boxes having any dimension over 1.8 m (6 ft), all conductors shall be cabled or racked up in an approved manner.

**(C) Covers.** All pull boxes, junction boxes, and conduit bodies shall be provided with covers compatible with the box or conduit body construction and suitable for the conditions of use. Where used, metal covers shall comply with the grounding requirements of 250.110.

**(D) Permanent Barriers.** Where permanent barriers are installed in a box, each section shall be considered as a separate box.

**(E) Power Distribution Blocks.** Power distribution blocks shall be permitted in pull and junction boxes over 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) for connections of conductors where installed in boxes and where the installation complies with (1) through (5).

*Exception: Equipment grounding terminal bars shall be permitted in smaller enclosures.*

**(1) Installation.** Power distribution blocks installed in boxes shall be listed.

**(2) Size.** In addition to the overall size requirement in the first sentence of 314.28(A)(2), the power distribution block shall be installed in a box with dimensions not smaller than specified in the installation instructions of the power distribution block.

**(3) Wire Bending Space.** Wire bending space at the terminals of power distribution blocks shall comply with 312.6.

**(4) Live Parts.** Power distribution blocks shall not have uninsulated live parts exposed within a box, whether or not the box cover is installed.

**(5) Through Conductors.** Where the pull or junction boxes are used for conductors that do not terminate on the power distribution block(s), the through conductors shall be tarranged so the power distribution block terminals are unobstructed following installation.

Section 314.28(E) is new for the 2011 *Code* and provides requirements for the installation of power distribution blocks as a termination or connection means for conductors contained within pull or junction boxes. Similar provisions already exist in Article 376 for wireways. The use in junction or pull boxes is limited to enclosures over 100 in.<sup>3</sup> However, equipment grounding terminal bars are permitted in smaller enclosures.

### 314.29 Boxes, Conduit Bodies, and Handhole Enclosures to Be Accessible

Boxes, conduit bodies, and handhole enclosures shall be installed so that the wiring contained in them can be rendered accessible without removing any part of the building or, in underground circuits, without excavating sidewalks, paving, earth, or other substance that is to be used to establish the finished grade.

*Exception: Listed boxes and handhole enclosures shall be permitted where covered by gravel, light aggregate, or non-cohesive granulated soil if their location is effectively identified and accessible for excavation.*

A junction box installed on a structural ceiling above a suspended ceiling, for example, is permitted to be used at any point for the connection of conduit, tubing, or cable, provided it is not rendered inaccessible. See Article 100 for the definition of *accessible (as applied to wiring methods)*. See 300.15 for other requirements for boxes, conduit bodies, fittings, or handholes.

### 314.30 Handhole Enclosures

Handhole enclosures shall be designed and installed to withstand all loads likely to be imposed on them. They shall be identified for use in underground systems.

**Informational Note:** See ANSI/SCTE 77-2002, *Specification for Underground Enclosure Integrity*, for additional information on deliberate and nondeliberate traffic loading that can be expected to bear on underground enclosures.

The term *loads* as used in 314.30 refers to the weight or force of traffic loads placed upon handhole enclosures, not electrical loads. The definition of *handhole enclosure*, found in Article 100, states that it is “an enclosure for use in underground systems, provided with an open or closed bottom, and sized to allow personnel to reach into, but not enter, for the purpose of installing, operating, or maintaining equipment or wiring or both.” The term *identified (as applied to equipment)* is defined in Article 100 as recognizably suitable for the intended purpose.

**(A) Size.** Handhole enclosures shall be sized in accordance with 314.28(A) for conductors operating at 600 volts or below, and in accordance with 314.71 for conductors operating at over 600 volts. For handhole enclosures without bottoms where the provisions of 314.28(A)(2), Exception, or 314.71(B)(1), Exception No. 1, apply, the measurement to the removable cover shall be taken from the end of the conduit or cable assembly.

**(B) Wiring Entries.** Underground raceways and cable assemblies entering a handhole enclosure shall extend into the enclosure, but they shall not be required to be mechanically connected to the enclosure.

**(C) Enclosed Wiring.** All enclosed conductors and any splices or terminations, if present, shall be listed as suitable for wet locations.

Due to the possibility of flooding within a handhole enclosure (bottomless or totally enclosed), 314.30(C) requires that the conductors, splices, and terminations be listed for use in a wet location. See also 300.5(B) and 310.10(C).

**(D) Covers.** Handhole enclosure covers shall have an identifying mark or logo that prominently identifies the function of the enclosure, such as “electric.” Handhole enclosure covers shall require the use of tools to open, or they shall weigh over 45 kg (100 lb). Metal covers and other exposed conductive surfaces shall be bonded in accordance with 250.92 if the conductors in the handhole are service conductors, or in accordance with 250.96(A) if the conductors in the handhole are feeder or branch-circuit conductors.

The term *other exposed conductive surfaces* often includes metal frames used to secure metal covers in place. No exceptions to the requirement are given for bonding the metal covers and other exposed conductive surfaces.

## III. Construction Specifications

### 314.40 Metal Boxes, Conduit Bodies, and Fittings

**(A) Corrosion Resistant.** Metal boxes, conduit bodies, and fittings shall be corrosion resistant or shall be well-galvanized, enameled, or otherwise properly coated inside and out to prevent corrosion.

**Informational Note:** See 300.6 for limitation in the use of boxes and fittings protected from corrosion solely by enamel.

**(B) Thickness of Metal.** Sheet steel boxes not over 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) in size shall be made from steel not less than 1.59 mm (0.0625 in.) thick. The wall of a malleable iron box or conduit body and a die-cast or permanent-mold cast aluminum, brass, bronze, or zinc box or conduit body shall not be less than 2.38 mm (<sup>3</sup>/<sub>32</sub> in.) thick. Other cast metal boxes or conduit bodies shall have a wall thickness not less than 3.17 mm (<sup>1</sup>/<sub>8</sub> in.).

*Exception No. 1: Listed boxes and conduit bodies shown to have equivalent strength and characteristics shall be permitted to be made of thinner or other metals.*

*Exception No. 2: The walls of listed short radius conduit bodies, as covered in 314.16(C)(2), shall be permitted to be made of thinner metal.*

**(C) Metal Boxes Over 1650 cm<sup>3</sup> (100 in.<sup>3</sup>).** Metal boxes over 1650 cm<sup>3</sup> (100 in.<sup>3</sup>) in size shall be constructed so as to be of ample strength and rigidity. If of sheet steel, the metal thickness shall not be less than 1.35 mm (0.053 in.) uncoated.

**(D) Grounding Provisions.** A means shall be provided in each metal box for the connection of an equipment grounding conductor. The means shall be permitted to be a tapped hole or equivalent.

For device boxes and other standard outlet boxes, the means for connecting the equipment grounding conductor, as required by 314.40(D), is usually provided by the box manufacturer in the form of a 10-32 tapped hole marked “GR” or “GRD,” or the equivalent, next to the hole. However, the means provided may not necessarily be used.

#### 314.41 Covers

Metal covers shall be of the same material as the box or conduit body with which they are used, or they shall be lined with firmly attached insulating material that is not less than 0.79 mm ( $\frac{1}{32}$  in.) thick, or they shall be listed for the purpose. Metal covers shall be the same thickness as the boxes or conduit body for which they are used, or they shall be listed for the purpose. Covers of porcelain or other approved insulating materials shall be permitted if of such form and thickness as to afford the required protection and strength.

#### 314.42 Bushings

Covers of outlet boxes and conduit bodies having holes through which flexible cord pendants may pass shall be provided with approved bushings or shall have smooth, well-rounded surfaces on which the cord may bear. Where individual conductors pass through a metal cover, a separate hole equipped with a bushing of suitable insulating material shall be provided for each conductor. Such separate holes shall be connected by a slot as required by 300.20.

#### 314.43 Nonmetallic Boxes

Provisions for supports or other mounting means for nonmetallic boxes shall be outside of the box, or the box shall be constructed so as to prevent contact between the conductors in the box and the supporting screws.

#### 314.44 Marking

All boxes and conduit bodies, covers, extension rings, plaster rings, and the like shall be durably and legibly marked with the manufacturer’s name or trademark.

### IV. Pull and Junction Boxes, Conduit Bodies, and Handhole Enclosures for Use on Systems over 600 Volts, Nominal

This part was revised for the 2011 *Code* to provide requirements for conduit bodies and handhole enclosures for systems over 600 volts.

#### 314.70 General

**(A) Pull and Junction Boxes.** Where pull and junction boxes are used on systems over 600 volts, the installation shall comply with the provisions of Part IV and with the following general provisions of this article:

- (1) Part I, 314.2; 314.3; and 314.4
- (2) Part II, 314.15; 314.17; 314.20; 314.23(A), (B), or (G); 314.28(B); and 314.29
- (3) Part III, 314.40(A) and (C); and 314.41

**(B) Conduit Bodies.** Where conduit bodies are used on systems over 600 volts, the installation shall comply with the provisions of Part IV and with the following general provisions of this article:

- (1) Part I, 314.4
- (2) Part II, 314.15; 314.17; 314.23(A), (E), or (G); and 314.29
- (3) Part III, 314.40(A); and 314.41

**(C) Handhole Enclosures.** Where handhole enclosures are used on systems over 600 volts, the installation shall comply with the provisions of Part IV and with the following general provisions of this article:

- (1) Part I, 314.3; and 314.4
- (2) Part II, 314.15; 314.17; 314.23(G); 314.28(B); 314.29; and 314.30

#### 314.71 Size of Pull and Junction Boxes, Conduit Bodies, and Handhole Enclosures

Pull and junction boxes and handhole enclosures shall provide adequate space and dimensions for the installation of conductors, and they shall comply with the specific requirements of this section. Conduit bodies shall be permitted if they meet the dimensional requirements for boxes.

*Exception: Terminal housings supplied with motors shall comply with the provisions of 430.12.*

**(A) For Straight Pulls.** The length of the box shall not be less than 48 times the outside diameter, over sheath, of the largest shielded or lead-covered conductor or cable entering the box. The length shall not be less than 32 times the outside diameter of the largest nonshielded conductor or cable.

**(B) For Angle or U Pulls.**

**(1) Distance to Opposite Wall.** The distance between each cable or conductor entry inside the box and the opposite wall of the box shall not be less than 36 times the outside diameter, over sheath, of the largest cable or conductor. This distance shall be increased for additional entries by the amount of the sum of the outside diameters, over sheath, of all other cables or conductor entries through the same wall of the box.

*Exception No. 1: Where a conductor or cable entry is in the wall of a box opposite a removable cover, the distance from that wall to the cover shall be permitted to be not less than the bending radius for the conductors as provided in 300.34.*

*Exception No. 2: Where cables are nonshielded and not lead covered, the distance of 36 times the outside diameter shall be permitted to be reduced to 24 times the outside diameter.*

**(2) Distance Between Entry and Exit.** The distance between a cable or conductor entry and its exit from the box shall not be less than 36 times the outside diameter, over sheath, of that cable or conductor.

*Exception: Where cables are nonshielded and not lead covered, the distance of 36 times the outside diameter shall be permitted to be reduced to 24 times the outside diameter.*

**(C) Removable Sides.** One or more sides of any pull box shall be removable.

### 314.72 Construction and Installation Requirements

**(A) Corrosion Protection.** Boxes shall be made of material inherently resistant to corrosion or shall be suitably protected, both internally and externally, by enameling, galvanizing, plating, or other means.

**(B) Passing Through Partitions.** Suitable bushings, shields, or fittings having smooth, rounded edges shall be provided where conductors or cables pass through partitions and at other locations where necessary.

**(C) Complete Enclosure.** Boxes shall provide a complete enclosure for the contained conductors or cables.

**(D) Wiring Is Accessible.** Boxes and conduit bodies shall be installed so that the conductors are accessible without removing any fixed part of the building or structure. Working space shall be provided in accordance with 110.34.

**(E) Suitable Covers.** Boxes shall be closed by suitable covers securely fastened in place. Underground box covers

that weigh over 45 kg (100 lb) shall be considered meeting this requirement. Covers for boxes shall be permanently marked “DANGER — HIGH VOLTAGE — KEEP OUT.” The marking shall be on the outside of the box cover and shall be readily visible. Letters shall be block type and at least 13 mm (½ in.) in height.

**(F) Suitable for Expected Handling.** Boxes and their covers shall be capable of withstanding the handling to which they are likely to be subjected.

### I. General

#### 320.1 Scope

This article covers the use, installation, and construction specifications for armored cable, Type AC.

Type AC (armored) cable is listed by Underwriters Laboratories in sizes 14 AWG through 1 AWG copper and 12 AWG

through 1 AWG aluminum or copper-clad aluminum and is rated at 600 volts or less. However, the *NEC* does not specifically require that Type AC cable be listed. Exhibit 320.1 shows an example of Type AC cable.

**EXHIBIT 320.1** An example of Type AC cable. (Courtesy of AFC Cable Systems, Inc.)

### 320.2 Definition

**Armored Cable, Type AC.** A fabricated assembly of insulated conductors in a flexible interlocked metallic armor. See 320.100.

This definition had some minor editorial revisions for the 2011 Code.

## II. Installation

### 320.10 Uses Permitted

Type AC cable shall be permitted as follows:

- (1) For feeders and branch circuits in both exposed and concealed installations
- (2) In cable trays
- (3) In dry locations
- (4) Embedded in plaster finish on brick or other masonry, except in damp or wet locations
- (5) To be run or fished in the air voids of masonry block or tile walls where such walls are not exposed or subject to excessive moisture or dampness

Informational Note: The “Uses Permitted” is not an all-inclusive list.

### 320.12 Uses Not Permitted

Type AC cable shall not be used as follows:

- (1) Where subject to physical damage
- (2) In damp or wet locations
- (3) In air voids of masonry block or tile walls where such walls are exposed or subject to excessive moisture or dampness
- (4) Where exposed to corrosive conditions
- (5) Embedded in plaster finish on brick or other masonry in damp or wet locations

### 320.15 Exposed Work

Exposed runs of cable, except as provided in 300.11(A), shall closely follow the surface of the building finish or of running boards. Exposed runs shall also be permitted to be installed on the underside of joists where supported at each joist and located so as not to be subject to physical damage.

### 320.17 Through or Parallel to Framing Members

Type AC cable shall be protected in accordance with 300.4(A), (C), and (D) where installed through or parallel to framing members.

### 320.23 In Accessible Attics

Type AC cables in accessible attics or roof spaces shall be installed as specified in 320.23(A) and (B).

**(A) Cables Run Across the Top of Floor Joists.** Where run across the top of floor joists, or within 2.1 m (7 ft) of the floor or floor joists across the face of rafters or studding, the cable shall be protected by substantial guard strips that are at least as high as the cable. Where this space is not accessible by permanent stairs or ladders, protection shall only be required within 1.8 m (6 ft) of the nearest edge of the scuttle hole or attic entrance.

Type AC cable installed in accessible attics across the top of floor joists or within 7 ft of the floor or floor joists across the face of rafters or studs must be protected by guard strips. Where the attic is not accessible by a permanent ladder or stairs, guard strips are required only within 6 ft of the scuttle hole or opening.

**(B) Cable Installed Parallel to Framing Members.** Where the cable is installed parallel to the sides of rafters, studs, or ceiling or floor joists, neither guard strips nor running boards shall be required, and the installation shall also comply with 300.4(D).

### 320.24 Bending Radius

Bends in Type AC cable shall be made such that the cable is not damaged. The radius of the curve of the inner edge of any bend shall not be less than five times the diameter of the Type AC cable.

### 320.30 Securing and Supporting

**(A) General.** Type AC cable shall be supported and secured by staples, cable ties, straps, hangers, or similar fittings, designed and installed so as not to damage the cable.

Section 320.30 requires that Type AC cable be secured. Simply draping the cable over air ducts or lower members of bar joists, pipes, and ceiling grid members is not permitted.

**(B) Securing.** Unless otherwise permitted, Type AC cable shall be secured within 300 mm (12 in.) of every outlet box, junction box, cabinet, or fitting and at intervals not exceeding 1.4 m (4½ ft) where installed on or across framing members.

**(C) Supporting.** Unless otherwise permitted, Type AC cable shall be supported at intervals not exceeding 1.4 m (4½ ft).

Horizontal runs of Type AC cable installed in wooden or metal framing members or similar supporting means shall be considered supported where such support does not exceed 1.4-m (4½-ft) intervals.

Section 320.30(C) permits Type AC cable, where run horizontally through framing members, to be passed through bored or punched holes in framing members without additional securing, provided the cable is secured within 12 in. of the outlet and the framing members are less than 54 in. apart.

**(D) Unsupported Cables.** Type AC cable shall be permitted to be unsupported where the cable complies with any of the following:

- (1) Is fished between access points through concealed spaces in finished buildings or structures and supporting is impracticable
- (2) Is not more than 600 mm (2 ft) in length at terminals where flexibility is necessary
- (3) Is not more than 1.8 m (6 ft) in length from the last point of cable support to the point of connection to a luminaire(s) or other electrical equipment and the cable and point of connection are within an accessible ceiling. For the purposes of this section, Type AC cable fittings shall be permitted as a means of cable support.

### 320.40 Boxes and Fittings

At all points where the armor of AC cable terminates, a fitting shall be provided to protect wires from abrasion, unless the design of the outlet boxes or fittings is such as to afford equivalent protection, and, in addition, an insulating bushing or its equivalent protection shall be provided between the conductors and the armor. The connector or clamp by which the Type AC cable is fastened to boxes or cabinets shall be of such design that the insulating bushing or its equivalent will be visible for inspection. Where change is made from Type AC cable to other cable or raceway wiring methods, a box, fitting, or conduit body shall be installed at junction points as required in 300.15.

An anti-short bushing (sometimes referred to as a “red head”), as required by 320.40, is shown in Exhibit 320.2. It is a plastic insert placed between the metal jacket of an AC cable and the insulated conductors at the point where the conductors emerge from the metal jacket of an AC cable. The anti-short bushing provides the insulated conductors with an additional level of short-circuit and ground-fault protection where they are most vulnerable.

**EXHIBIT 320.2** An anti-short bushing designed to protect insulated conductors from abrasion according to 320.40. (Courtesy of Cooper Crouse-Hinds)

Armored cable connectors are considered suitable for equipment grounding if installed in accordance with 300.10.

### 320.80 Ampacity

The ampacity shall be determined in accordance with 310.15.

**(A) Thermal Insulation.** Armored cable installed in thermal insulation shall have conductors rated at 90°C (194°F). The ampacity of cable installed in these applications shall not exceed that of a 60°C (140°F) rated conductor. The 90°C (194°F) rating shall be permitted to be used for ampacity adjustment and correction calculations; however, the ampacity shall not exceed that of a 60°C (140°F) rated conductor.

The requirements in 320.80(A) for armored cable installed in thermal insulation recognize the decrease in heat dissipation capability of cables. Cable marked “ACTH” indicates an armored cable rated 75°C and employing conductors having thermoplastic insulation. Cable marked “ACTHH” indicates an armored cable rated 90°C and employing conductors having thermoplastic insulation. Cable marked “ACHH” indicates armored cable rated 90°C and employing conductors having thermosetting insulation. Where conductors are rated 90°C, the 90°C ampacity can be used for derating.

**(B) Cable Tray.** The ampacity of Type AC cable installed in cable tray shall be determined in accordance with 392.80(A).

### III. Construction Specifications

#### 320.100 Construction

Type AC cable shall have an armor of flexible metal tape and shall have an internal bonding strip of copper or aluminum in intimate contact with the armor for its entire length.

The armor of Type AC cable is recognized as an equipment grounding conductor by 250.118, and the internal bonding strip required by 320.100 can simply be cut off at the termination of the armored cable, or it can be bent back on the armor. It is not necessary to connect it to an equipment grounding terminal. It reduces the inductive reactance of the spiral armor and increases the armor’s effectiveness as an equipment ground. Many installers use this strip to help prevent the insulating (anti-short) bushing required by 320.40 (the “red head”) from falling out during rough wiring.

#### 320.104 Conductors

Insulated conductors shall be of a type listed in Table 310.104(A) or those identified for use in this cable. In addition, the conductors shall have an overall moisture-resistant and fire-retardant fibrous covering. For Type ACT, a moisture-resistant fibrous covering shall be required only on the individual conductors.

#### 320.108 Equipment Grounding Conductor

Type AC cable shall provide an adequate path for fault current as required by 250.4(A)(5) or (B)(4) to act as an equipment grounding conductor.

#### 320.120 Marking

The cable shall be marked in accordance with 310.120, except that Type AC shall have ready identification of the manufacturer by distinctive external markings on the cable armor throughout its entire length.

    - (C) Terminal Block Identification

### I. General

#### 322.1 Scope

This article covers the use, installation, and construction specifications for flat cable assemblies, Type FC.

Type FC (flat) cable is an assembly of three or four parallel 10 AWG special stranded copper wires formed integrally

with an insulating material web. The cable is marked with the size of the maximum branch circuit to which it may be connected, the cable type designation, manufacturer's identification, maximum working voltage, conductor size, and temperature rating. A marking accompanying the cable on a tag or reel indicates the special metal raceways and specific FC cable fittings with which the cable is intended to be used. Exhibits 322.1 and 322.2 show the basic components of this wiring method.

**EXHIBIT 322.1** Basic components and accessories used for an installation of Type FC cable assembly. (Courtesy of Legrand/Wiremold®)

### 322.2 Definition

**Flat Cable Assembly, Type FC.** An assembly of parallel conductors formed integrally with an insulating material web specifically designed for field installation in surface metal raceway.

**EXHIBIT 322.2** A luminaire hanger used with Type FC cable assembly. (Courtesy of Legrand/Wiremold®)

## II. Installation

### 322.10 Uses Permitted

Flat cable assemblies shall be permitted only as follows:

- (1) As branch circuits to supply suitable tap devices for lighting, small appliances, or small power loads. The rating of the branch circuit shall not exceed 30 amperes.
- (2) Where installed for exposed work.
- (3) In locations where they will not be subjected to physical damage. Where a flat cable assembly is installed less than 2.5 m (8 ft) above the floor or fixed working platform, it shall be protected by a cover identified for the use.
- (4) In surface metal raceways identified for the use. The channel portion of the surface metal raceway systems shall be installed as complete systems before the flat cable assemblies are pulled into the raceways.

### 322.12 Uses Not Permitted

Flat cable assemblies shall not be used as follows:

- (1) Where exposed to corrosive conditions, unless suitable for the application
- (2) In hoistways or on elevators or escalators
- (3) In any hazardous (classified) location, except as specifically permitted by other articles in this Code

- (4) Outdoors or in wet or damp locations unless identified for the use

### 322.30 Securing and Supporting

The flat cable assemblies shall be supported by means of their special design features, within the surface metal raceways.

The surface metal raceways shall be supported as required for the specific raceway to be installed.

### 322.40 Boxes and Fittings

(A) **Dead Ends.** Each flat cable assembly dead end shall be terminated in an end-cap device identified for the use.

The dead-end fitting for the enclosing surface metal raceway shall be identified for the use.

(B) **Luminaire Hangers.** Luminaire hangers installed with the flat cable assemblies shall be identified for the use.

(C) **Fittings.** Fittings to be installed with flat cable assemblies shall be designed and installed to prevent physical damage to the cable assemblies.

(D) **Extensions.** All extensions from flat cable assemblies shall be made by approved wiring methods, within the junction boxes, installed at either end of the flat cable assembly runs.

### 322.56 Splices and Taps

(A) **Splices.** Splices shall be made in listed junction boxes.

(B) **Taps.** Taps shall be made between any phase conductor and the grounded conductor or any other phase conductor by means of devices and fittings identified for the use. Tap devices shall be rated at not less than 15 amperes, or more than 300 volts to ground, and shall be color-coded in accordance with the requirements of 322.120(C).

## III. Construction

### 322.100 Construction

Flat cable assemblies shall consist of two, three, four, or five conductors.

### 322.104 Conductors

Flat cable assemblies shall have conductors of 10 AWG special stranded copper wires.

### 322.112 Insulation

The entire flat cable assembly shall be formed to provide a suitable insulation covering all the conductors and using one of the materials recognized in Table 310.104(A) for general branch-circuit wiring.

### 322.120 Marking

(A) **Temperature Rating.** In addition to the provisions of 310.120, Type FC cable shall have the temperature rating durably marked on the surface at intervals not exceeding 600 mm (24 in.).

(B) **Identification of Grounded Conductor.** The grounded conductor shall be identified throughout its length by means of a distinctive and durable white or gray marking.

Informational Note: The color gray may have been used in the past as an ungrounded conductor. Care should be taken when working on existing systems.

(C) **Terminal Block Identification.** Terminal blocks identified for the use shall have distinctive and durable markings for color or word coding. The grounded conductor section shall have a white marking or other suitable designation. The next adjacent section of the terminal block shall have a black marking or other suitable designation. The next section shall have a red marking or other suitable designation. The final or outer section, opposite the grounded conductor section of the terminal block, shall have a blue marking or other suitable designation.

## I. General

### 324.1 Scope

This article covers a field-installed wiring system for branch circuits incorporating Type FCC cable and associated accessories as defined by the article. The wiring system is designed for installation under carpet squares.

The FCC (flat conductor cable) system is designed to provide a completely accessible, flexible power system. As shown in Exhibit 324.1, it also provides an easy method for reworking obsolete wiring systems currently in use in many office facilities. The carpet squares are not permitted to be larger than 36 in. × 36 in., to comply with 324.41. This limitation provides ready access to the cable by lifting a carpet

**EXHIBIT 324.1** Type FCC cable installed beneath carpet squares. (Courtesy of Tyco Electronics)

square. It also reduces the likelihood of damage to the cable by an individual cutting through the carpet above the cable with a knife or razor blade and possibly penetrating the top shield of the cable in the process.

### 324.2 Definitions

**Bottom Shield.** A protective layer that is installed between the floor and Type FCC flat conductor cable to protect the cable from physical damage and may or may not be incorporated as an integral part of the cable.

**Cable Connector.** A connector designed to join Type FCC cables without using a junction box.

**FCC System.** A complete wiring system for branch circuits that is designed for installation under carpet squares. The FCC system includes Type FCC cable and associated shielding, connectors, terminators, adapters, boxes, and receptacles.

**Insulating End.** An insulator designed to electrically insulate the end of a Type FCC cable.

**Metal Shield Connections.** Means of connection designed to electrically and mechanically connect a metal shield to another metal shield, to a receptacle housing or self-contained device, or to a transition assembly.

**Top Shield.** A grounded metal shield covering under-carpet components of the FCC system for the purposes of providing protection against physical damage.

**Transition Assembly.** An assembly to facilitate connection of the FCC system to other wiring systems, incorporating (1) a means of electrical interconnection and (2) a suitable box or covering for providing electrical safety and protection against physical damage.

**Type FCC Cable.** Three or more flat copper conductors placed edge-to-edge and separated and enclosed within an insulating assembly.

### 324.6 Listing Requirements

Type FCC cable and associated fittings shall be listed.

## II. Installation

### 324.10 Uses Permitted

(A) **Branch Circuits.** Use of FCC systems shall be permitted both for general-purpose and appliance branch circuits and for individual branch circuits.

(B) **Branch-Circuit Ratings.**

(1) **Voltage.** Voltage between ungrounded conductors shall not exceed 300 volts. Voltage between ungrounded conductors and the grounded conductor shall not exceed 150 volts.

**(2) Current.** General-purpose and appliance branch circuits shall have ratings not exceeding 20 amperes. Individual branch circuits shall have ratings not exceeding 30 amperes.

**(C) Floors.** Use of FCC systems shall be permitted on hard, sound, smooth, continuous floor surfaces made of concrete, ceramic, or composition flooring, wood, and similar materials.

**(D) Walls.** Use of FCC systems shall be permitted on wall surfaces in surface metal raceways.

**(E) Damp Locations.** Use of FCC systems in damp locations shall be permitted.

**(F) Heated Floors.** Materials used for floors heated in excess of 30°C (86°F) shall be identified as suitable for use at these temperatures.

**(G) System Height.** Any portion of an FCC system with a height above floor level exceeding 2.3 mm (0.090 in.) shall be tapered or feathered at the edges to floor level.

### 324.12 Uses Not Permitted

FCC systems shall not be used in the following locations:

- (1) Outdoors or in wet locations
- (2) Where subject to corrosive vapors
- (3) In any hazardous (classified) location
- (4) In residential, school, and hospital buildings

Section 324.12(4) prohibits Type FCC wiring systems throughout school and hospital buildings, even though parts of these buildings may be office or administrative spaces.

### 324.18 Crossings

Crossings of more than two Type FCC cable runs shall not be permitted at any one point. Crossings of a Type FCC cable over or under a flat communications or signal cable shall be permitted. In each case, a grounded layer of metal shielding shall separate the two cables, and crossings of more than two flat cables shall not be permitted at any one point.

### 324.30 Securing and Supporting

All FCC system components shall be firmly anchored to the floor or wall using an adhesive or mechanical anchoring system identified for this use. Floors shall be prepared to ensure adherence of the FCC system to the floor until the carpet squares are placed.

### 324.40 Boxes and Fittings

**(A) Cable Connections and Insulating Ends.** All Type FCC cable connections shall use connectors identified for

their use, installed such that electrical continuity, insulation, and sealing against dampness and liquid spillage are provided. All bare cable ends shall be insulated and sealed against dampness and liquid spillage using listed insulating ends.

**(B) Polarization of Connections.** All receptacles and connections shall be constructed and installed so as to maintain proper polarization of the system.

### (C) Shields.

**(1) Top Shield.** A metal top shield shall be installed over all floor-mounted Type FCC cable, connectors, and insulating ends. The top shield shall completely cover all cable runs, corners, connectors, and ends.

**(2) Bottom Shield.** A bottom shield shall be installed beneath all Type FCC cable, connectors, and insulating ends.

**(D) Connection to Other Systems.** Power feed, grounding connection, and shield system connection between the FCC system and other wiring systems shall be accomplished in a transition assembly identified for this use.

**(E) Metal-Shield Connectors.** Metal shields shall be connected to each other and to boxes, receptacle housings, self-contained devices, and transition assemblies using metal-shield connectors.

### 324.41 Floor Coverings

Floor-mounted Type FCC cable, cable connectors, and insulating ends shall be covered with carpet squares not larger than 914 mm (36 in.) square. Carpet squares that are adhered to the floor shall be attached with release-type adhesives.

### 324.42 Devices

**(A) Receptacles.** All receptacles, receptacle housings, and self-contained devices used with the FCC system shall be identified for this use and shall be connected to the Type FCC cable and metal shields. Connection from any grounding conductor of the Type FCC cable shall be made to the shield system at each receptacle.

**(B) Receptacles and Housings.** Receptacle housings and self-contained devices designed either for floor mounting or for in-wall or on-wall mounting shall be permitted for use with the FCC system. Receptacle housings and self-contained devices shall incorporate means for facilitating entry and termination of Type FCC cable and for electrically connecting the housing or device with the metal shield. Receptacles and self-contained devices shall comply with 406.4. Power and communications outlets installed together in common housing shall be permitted in accordance with 800.133(A)(1)(c), Exception No. 2.

### 324.56 Splices and Taps

**(A) FCC Systems Alterations.** Alterations to FCC systems shall be permitted. New cable connectors shall be used at new connection points to make alterations. It shall be permitted to leave unused cable runs and associated cable connectors in place and energized. All cable ends shall be covered with insulating ends.

**(B) Transition Assemblies.** All transition assemblies shall be identified for their use. Each assembly shall incorporate means for facilitating entry of the Type FCC cable into the assembly, for connecting the Type FCC cable to grounded conductors, and for electrically connecting the assembly to the metal cable shields and to equipment grounding conductors.

### 324.60 Grounding

All metal shields, boxes, receptacle housings, and self-contained devices shall be electrically continuous to the equipment grounding conductor of the supplying branch circuit. All such electrical connections shall be made with connectors identified for this use. The electrical resistivity of such shield system shall not be more than that of one conductor of the Type FCC cable used in the installation.

## III. Construction

### 324.100 Construction

**(A) Type FCC Cable.** Type FCC cable shall be listed for use with the FCC system and shall consist of three, four, or five flat copper conductors, one of which shall be an equipment grounding conductor.

#### **(B) Shields.**

**(1) Materials and Dimensions.** All top and bottom shields shall be of designs and materials identified for their use. Top shields shall be metal. Both metallic and nonmetallic materials shall be permitted for bottom shields.

**(2) Resistivity.** Metal shields shall have cross-sectional areas that provide for electrical resistivity of not more than that of one conductor of the Type FCC cable used in the installation.

### 324.101 Corrosion Resistance

Metal components of the system shall be either corrosion resistant, coated with corrosion-resistant materials, or insulated from contact with corrosive substances.

### 324.112 Insulation

The insulating material of the cable shall be moisture resistant and flame retardant. All insulating materials in the FCC systems shall be identified for their use.

### 324.120 Markings

**(A) Cable Marking.** Type FCC cable shall be clearly and durably marked on both sides at intervals of not more than 610 mm (24 in.) with the information required by 310.120(A) and with the following additional information:

- (1) Material of conductors
- (2) Maximum temperature rating
- (3) Ampacity

**(B) Conductor Identification.** Conductors shall be clearly and durably identified on both sides throughout their length as specified in 310.110.

## ARTICLE 326 Integrated Gas Spacer Cable: Type IGS

### Contents

  - 326.104 Conductors
  - 326.112 Insulation
  - 326.116 Conduit
  - 326.120 Marking

## I. General

### 326.1 Scope

This article covers the use, installation, and construction specifications for integrated gas spacer cable, Type IGS.

As illustrated in Exhibit 326.1, Type IGS (integrated gas spacer) cable consists of solid aluminum rod conductors, 250-kcmil minimum size. These conductors are insulated with dry kraft paper and are factory installed in a medium-density polyethylene gas pipe, minimum trade size 2, which is then filled with sulfur hexafluoride (SF<sub>6</sub>) gas at a pressure of approximately 20 psi.

### 326.2 Definition

**Integrated Gas Spacer Cable, Type IGS.** A factory assembly of one or more conductors, each individually insulated and enclosed in a loose fit, nonmetallic flexible conduit as an integrated gas spacer cable rated 0 through 600 volts.

## II. Installation

### 326.10 Uses Permitted

Type IGS cable shall be permitted for use under ground, including direct burial in the earth, as the following:

- (1) Service-entrance conductors
- (2) Feeder or branch-circuit conductors
- (3) Service-lateral conductors

### 326.12 Uses Not Permitted

Type IGS cable shall not be used as interior wiring or be exposed in contact with buildings.

### 326.24 Bending Radius

Where the coilable nonmetallic conduit and cable is bent for installation purposes or is flexed or bent during shipment or installation, the radii of bends measured to the inside of the bend shall not be less than specified in Table 326.24.

**TABLE 326.24** Minimum Radii of Bends

Conduit Size		Minimum Radii	
Metric Designator	Trade Size	mm	in.
53	2	600	24
78	3	900	35
103	4	1150	45

### 326.26 Bends

A run of Type IGS cable between pull boxes or terminations shall not contain more than the equivalent of four quarter bends (360 degrees total), including those bends located immediately at the pull box or terminations.

### 326.40 Fittings

Terminations and splices for Type IGS cable shall be identified as a type that is suitable for maintaining the gas pressure within the conduit. A valve and cap shall be provided for each length of the cable and conduit to check the gas pressure or to inject gas into the conduit.

### 326.80 Ampacity

The ampacity of Type IGS cable shall not exceed the values shown in Table 326.80.

**TABLE 326.80** Ampacity of Type IGS Cable

Size (kcmil)	Amperes	Size (kcmil)	Amperes
250	119	2500	376
500	168	3000	412
750	206	3250	429
1000	238	3500	445
1250	266	3750	461
1500	292	4000	476
1750	315	4250	491
2000	336	4500	505
2250	357	4750	519

## III. Construction Specifications

### 326.104 Conductors

The conductors shall be solid aluminum rods, laid parallel, consisting of one to nineteen 12.7 mm (½ in.) diameter rods. The minimum conductor size shall be 250 kcmil, and the maximum size shall be 4750 kcmil.

### 326.112 Insulation

The insulation shall be dry kraft paper tapes and a pressurized sulfur hexafluoride gas (SF<sub>6</sub>), both approved for electrical use. The nominal gas pressure shall be 138 kPa gauge (20 lb/in.<sup>2</sup> gauge). The thickness of the paper spacer shall be as specified in Table 326.112.

### 326.116 Conduit

The conduit shall be a medium density polyethylene identified as suitable for use with natural gas rated pipe in metric designator 53, 78, or 103 (trade size 2, 3, or 4). The percent fill dimensions for the conduit are shown in Table 326.116.

TABLE 326.112 Paper Spacer Thickness

Size (kcmil)	Thickness	
	mm	in.
250–1000	1.02	0.040
1250–4750	1.52	0.060

TABLE 326.116 Conduit Dimensions

Conduit Size		Actual Outside Diameter		Actual Inside Diameter	
Metric Designator	Trade Size	mm	in.	mm	in.
53	2	60	2.375	49.46	1.947
78	3	89	3.500	73.30	2.886
103	4	114	4.500	94.23	3.710

The size of the conduit permitted for each conductor size shall be calculated for a percent fill not to exceed those found in Table 1, Chapter 9.

326.120 Marking

The cable shall be marked in accordance with 310.120(A), 310.120(B)(1), and 310.120(D).

ARTICLE 328

Medium Voltage Cable: Type MV

Contents

- I. General
- 328.1 Scope
- 328.2 Definition
- II. Installation
- 328.10 Uses Permitted
- 328.12 Uses Not Permitted
- 328.14 Installation
- 328.80 Ampacity
- III. Construction Specifications
- 328.100 Construction
- 328.120 Marking

I. General

328.1 Scope

This article covers the use, installation, and construction specifications for medium voltage cable, Type MV.

Type MV (medium voltage) cables are rated 2001 to 35,000 volts. Requirements for shielding are found in 310.10(E) and 310.10(F). If MV cables are installed in underground installations, they must comply with 300.50.

328.2 Definition

**Medium Voltage Cable, Type MV.** A single or multiconductor solid dielectric insulated cable rated 2001 volts or higher.

II. Installation

328.10 Uses Permitted

Type MV cable shall be permitted for use on power systems rated up to and including 35,000 volts, nominal, as follows:

- (1) In wet or dry locations.
- (2) In raceways.
- (3) In cable trays, where identified for the use, in accordance with 392.10, 392.20(B), (C), and (D), 392.22(C), 392.30(B)(1), 392.46, 392.56, and 392.60. Type MV cable that has an overall metallic sheath or armor, complies with the requirements for Type MC cable, and is identified as “MV or MC” shall be permitted to be installed in cable trays in accordance with 392.10(B)(2).
- (4) Direct buried in accordance with 300.50.
- (5) In messenger-supported wiring in accordance with Part II of Article 396.
- (6) As exposed runs in accordance with 300.37. Type MV cable that has an overall metallic sheath or armor, complies with the requirements for Type MC cable, and is identified as “MV or MC” shall be permitted to be installed as exposed runs of metal-clad cable in accordance with 300.37.

Informational Note: The “Uses Permitted” is not an all-inclusive list.

Type MV cables intended for installation in cable trays in accordance with Article 392 are marked “For CT Use” or “For Use in Cable Trays.” Where marked “MV or MC” the cable complies with the crush and impact rating associated with MC cable. Cable marked “MV or MC” is permitted to be installed in accordance with Article 330 as well as Article 392.

328.12 Uses Not Permitted

Type MV cable shall not be used where exposed to direct sunlight, unless identified for the use.

328.14 Installation

Type MV cable shall be installed, terminated, and tested by qualified persons.

This section and the informational note were added for the 2011 *Code* to highlight the complexity of working with Type MV cable. See the definition of *qualified person* in Article 100.

Informational Note: IEEE 576-2000, *Recommended Practice for Installation, Termination, and Testing of Insulated Power Cables as Used in Industrial and Commercial Applications*, includes installation information and testing criteria for MV cable.

### 328.80 Ampacity

The ampacity of Type MV cable shall be determined in accordance with 310.60. The ampacity of Type MV cable installed in cable tray shall be determined in accordance with 392.80(B).

## III. Construction Specifications

### 328.100 Construction

Type MV cables shall have copper, aluminum, or copper-clad aluminum conductors and shall comply with Table 310.104(C) and Table 310.104(D) or Table 310.104(E).

See the commentary and tables following 310.104.

### 328.120 Marking

Medium voltage cable shall be marked as required by 310.120.

In addition to the marking requirements of 310.120, insulation-level marking requirements include 100 percent, 133 percent, and 173 percent. These insulation levels are explained in the notes to Table 310.104(E). Shielded cable is marked “MV-90” and “MV-105” and is suitable for use in both dry and wet locations at both 90°C and 105°C. Additionally, the *UL Guide Information for Electrical Equipment — The White Book-2010*, in category PITY, gives examples of required and optional marking.

## I. General

### 330.1 Scope

This article covers the use, installation, and construction specifications of metal-clad cable, Type MC.

Type MC (metal-clad) cable is rated for use up to 2000 volts and is listed in sizes 18 AWG and larger for copper and 12 AWG and larger for aluminum or copper-clad aluminum. Type MC cable employs thermoset or thermoplastic insulated conductors. Composite electrical MC and optical fiber cables are permitted by 770.3(B) and are marked “MC-OF.” See Exhibit 770.2 for an example.

Type MC cable must be marked with the maximum rated voltage, the proper insulation type letter or letters, and the AWG size or circular mil area. This marking may be on a marker tape located within the cable and running its complete length, or, if the metallic covering is of smooth construction that permits surface marking, the MC cable may be durably marked on the outer covering at intervals not exceeding 24 in. For MC cable with an outer nonmetallic

covering, the marking is permitted on the surface of the non-metallic jacket. See 310.120 for marking requirements.

Type MC cable is available in three designs: interlocked metal tape, corrugated metal tube, and smooth metal tube. A nonmetallic jacket may be provided over the metal sheath. Cables suitable for use in cable trays, direct sunlight, or direct burial applications are so marked. Exhibit 330.1 shows some examples of Type MC cable.

**EXHIBIT 330.1** Examples of Type MC cable. (Courtesy of AFC Cable Systems, Inc.)

The basic standard to investigate products in this category is UL 1569, *Standard for Metal-Clad Cables*. Summary information regarding listed metal-clad cable may be found in the *UL Guide Information for Electrical Equipment — The White Book-2010*, under category PJAZ.

## 330.2 Definition

**Metal Clad Cable, Type MC.** A factory assembly of one or more insulated circuit conductors with or without optical fiber members enclosed in an armor of interlocking metal tape, or a smooth or corrugated metallic sheath.

## II. Installation

### 330.10 Uses Permitted

**(A) General Uses.** Type MC cable shall be permitted as follows:

- (1) For services, feeders, and branch circuits.
- (2) For power, lighting, control, and signal circuits.
- (3) Indoors or outdoors.
- (4) Exposed or concealed.
- (5) To be direct buried where identified for such use.
- (6) In cable tray where identified for such use.
- (7) In any raceway.

- (8) As aerial cable on a messenger.
- (9) In hazardous (classified) locations where specifically permitted by other articles in this Code.
- (10) In dry locations and embedded in plaster finish on brick or other masonry except in damp or wet locations.
- (11) In wet locations where any of the following conditions are met:
  - a. The metallic covering is impervious to moisture.
  - b. A moisture-impervious jacket is provided under the metal covering.
  - c. The insulated conductors under the metallic covering are listed for use in wet locations, and a corrosion-resistant jacket is provided over the metallic sheath.
- (12) Where single-conductor cables are used, all phase conductors and, where used, the grounded conductor shall be grouped together to minimize induced voltage on the sheath.

Single-conductor Type MC cable is permitted to be used according to 330.10(A)(12). Installation practice for single-conductor wiring methods dictates close circuit conductor spacing not only to minimize induced voltage on the sheath, but also to minimize overall circuit impedance.

**(B) Specific Uses.** Type MC cable shall be permitted to be installed in compliance with Parts II and III of Article 725 and 770.133 as applicable and in accordance with 330.10(B)(1) through (B)(4).

**(1) Cable Tray.** Type MC cable installed in cable tray shall comply with 392.10, 392.12, 392.18, 392.20, 392.22, 392.30, 392.46, 392.56, 392.60(C), and 392.80.

**(2) Direct Buried.** Direct-buried cable shall comply with 300.5 or 300.50, as appropriate.

**(3) Installed as Service-Entrance Cable.** Type MC cable installed as service-entrance cable shall be permitted in accordance with 230.43.

**(4) Installed Outside of Buildings or Structures or as Aerial Cable.** Type MC cable installed outside of buildings or structures or as aerial cable shall comply with 225.10, 396.10, and 396.12.

Informational Note: The “Uses Permitted” is not an all-inclusive list.

### 330.12 Uses Not Permitted

Type MC cable shall not be used under either of the following conditions:

- (1) Where subject to physical damage
- (2) Where exposed to any of the destructive corrosive conditions in (a) or (b), unless the metallic sheath or armor is resistant to the conditions or is protected by material resistant to the conditions:
  - a. Direct buried in the earth or embedded in concrete unless identified for direct burial
  - b. Exposed to cinder fills, strong chlorides, caustic alkalis, or vapors of chlorine or of hydrochloric acids

### 330.17 Through or Parallel to Framing Members

Type MC cable shall be protected in accordance with 300.4(A), (C), and (D) where installed through or parallel to framing members.

### 330.23 In Accessible Attics

The installation of Type MC cable in accessible attics or roof spaces shall also comply with 320.23.

In accessible attics, Type MC cable installed across the top of floor joists or within 7 ft of the floor or floor joists across the face of rafters or studs must be protected by guard strips. Where the attic is not accessible by a permanent ladder or stairs, guard strips are required only within 6 ft of the scuttle hole or opening.

### 330.24 Bending Radius

Bends in Type MC cable shall be so made that the cable will not be damaged. The radius of the curve of the inner edge of any bend shall not be less than required in 330.24(A) through (C).

#### (A) Smooth Sheath.

- (1) Ten times the external diameter of the metallic sheath for cable not more than 19 mm ( $\frac{3}{4}$  in.) in external diameter
- (2) Twelve times the external diameter of the metallic sheath for cable more than 19 mm ( $\frac{3}{4}$  in.) but not more than 38 mm ( $1\frac{1}{2}$  in.) in external diameter
- (3) Fifteen times the external diameter of the metallic sheath for cable more than 38 mm ( $1\frac{1}{2}$  in.) in external diameter

**(B) Interlocked-Type Armor or Corrugated Sheath.** Seven times the external diameter of the metallic sheath.

**(C) Shielded Conductors.** Twelve times the overall diameter of one of the individual conductors or seven times the overall diameter of the multiconductor cable, whichever is greater.

The minimum bending radius of 12 times the outside diameter (OD) of a single shielded conductor required by 330.24(A)(2) is consistent with Insulated Cable Engineers Association (ICEA) requirements and good engineering practice. However, as indicated in 330.24(C), the minimum bending radius for a shielded multiconductor cable is either 7 times the outside diameter of the overall cable or 12 times the overall diameter of one of the individual conductors in the cable, whichever is larger.

### 330.30 Securing and Supporting

**(A) General.** Type MC cable shall be supported and secured by staples, cable ties, straps, hangers, or similar fittings or other approved means designed and installed so as not to damage the cable.

There is a difference between securing and supporting. Type MC cable that runs horizontally through or on framing members or racks (spaced less than 6 ft apart) without additional securing is considered supported. Staples or cable ties are not required as the cable passes through or on these members. However, the MC cable must be secured (fastened in place) within 12 in. of the outlet box. Staples, cable ties, or clamps would be necessary to secure a cable.

**(B) Securing.** Unless otherwise provided, cables shall be secured at intervals not exceeding 1.8 m (6 ft). Cables containing four or fewer conductors sized no larger than 10 AWG shall be secured within 300 mm (12 in.) of every box, cabinet, fitting, or other cable termination.

Section 330.30(B) contains the general requirements for supporting and securing Type MC cable. It must be secured at least every 6 ft. Additionally, MC cable containing four or fewer conductors of size 10 AWG or less is required to be secured within 12 in. from every box, cabinet, or fitting. Both requirements are illustrated in Exhibit 330.2.

**(C) Supporting.** Unless otherwise provided, cables shall be supported at intervals not exceeding 1.8 m (6 ft).

Horizontal runs of Type MC cable installed in wooden or metal framing members or similar supporting means shall be considered supported and secured where such support does not exceed 1.8-m (6-ft) intervals.

**(D) Unsupported Cables.** Type MC cable shall be permitted to be unsupported where the cable:

- (1) Is fished between access points through concealed spaces in finished buildings or structures and supporting is impractical; or

**EXHIBIT 330.2** An application of 330.30(B), showing Type MC cable supported and secured at intervals not exceeding 6 ft and within 12 in. of the box, and an application of 330.30(D)(1), which permits Type MC cable to be fished in walls, floors, or ceilings.

- (2) Is not more than 1.8 m (6 ft) in length from the last point of cable support to the point of connection to luminaires or other electrical equipment and the cable and point of connection are within an accessible ceiling. For the purpose of this section, Type MC cable fittings shall be permitted as a means of cable support.

Section 330.30(D)(1) permits Type MC cable to be fished. Section 330.30(D)(2) permits listed MC cable fittings to support the last 6 ft of MC cable supplying a luminaire in an accessible ceiling. This use is in accord with 320.30(D)(3) for Type AC cable.

### 330.31 Single Conductors

Where single-conductor cables with a nonferrous armor or sheath are used, the installation shall comply with 300.20.

### 330.40 Boxes and Fittings

Fittings used for connecting Type MC cable to boxes, cabinets, or other equipment shall be listed and identified for such use.

Connectors should be selected in accordance with the size and type of cable for which they are designed. Bronze

connectors are intended for use only with cable employing corrugated copper armor. Some Type AC cable connectors are also acceptable and listed for use with Type MC cable when specifically indicated on the fitting or the shipping carton.

### 330.80 Ampacity

The ampacity of Type MC cable shall be determined in accordance with 310.15 or 310.60 for 14 AWG and larger conductors and in accordance with Table 402.5 for 18 AWG and 16 AWG conductors. The installation shall not exceed the temperature ratings of terminations and equipment.

**(A) Type MC Cable Installed in Cable Tray.** The ampacities for Type MC cable installed in cable tray shall be determined in accordance with 392.80.

**(B) Single Type MC Conductors Grouped Together.** Where single Type MC conductors are grouped together in a triangular or square configuration and installed on a messenger or exposed with a maintained free airspace of not less than 2.15 times one conductor diameter ( $2.15 \times \text{O.D.}$ ) of the largest conductor contained within the configuration and adjacent conductor configurations or cables, the ampacity of the conductors shall not exceed the allowable ampacities in the following tables:

- (1) Table 310.15(B)(20) for conductors rated 0 through 2000 volts
- (2) Table 310.60(C)(67) and Table 310.60(C)(68) for conductors rated over 2000 volts

### III. Construction Specifications

#### 330.104 Conductors

Conductors shall be of copper, aluminum, copper-clad aluminum, nickel or nickel-coated copper, solid or stranded. The minimum conductor size shall be 18 AWG copper, nickel or nickel-coated copper, or 12 AWG aluminum or copper-clad aluminum.

The *Code* permits conductor material of nickel and nickel-coated copper. These metals are used as conductors in some fire-rated MC cables. The use of conductor material of nickel and nickel-coated copper is already permitted by 310.106(B) and is listed in Table 310.104(A) for insulation types PFAH and TFE (and used in high-temperature applications).

#### 330.108 Equipment Grounding Conductor

Where Type MC cable is used to provide an equipment grounding conductor, it shall comply with 250.118(10) and 250.122.

The equipment grounding conductor in a multiconductor Type MC cable may be either single or segmented. Where it is segmented, the individual segments must have a total cross-sectional area of not less than that required by 250.122 for a single conductor. The equipment grounding conductor must be an integral part of the multiconductor Type MC cable. It cannot be strapped to the exterior of the cable.

The following commentary applies only to installations of single-conductor Type MC cable. If single Type MC conductors are installed as open runs or as messenger-supported wiring, the smooth or corrugated metallic sheath on each conductor must have sufficient cross-sectional area to comply with Table 250.122, or concentric conductors may be provided over the conductor under the metallic sheath. Either the metallic sheath or the combination of the concentric conductors in parallel with the metallic sheath may be used to provide the required equipment grounding path. For single Type MC conductors with an interlocking metal tape armor installed as open runs or as messenger-supported wiring, concentric conductors must be provided over the conductor under

the metallic sheath. The total cross-sectional area of the concentric conductors must comply with Table 250.122.

If single Type MC conductors are installed in cable tray, the cable tray, an equipment grounding conductor(s) within the cable tray, and/or the equipment grounding provided with the single conductor may be used individually or in any parallel combination to provide the equipment grounding path required by 392.60(A) and 250.118.

If single Type MC conductors are installed underground in a trench, a separate equipment grounding conductor may be installed in close proximity to the circuit conductors within the same trench. The separate equipment grounding conductor may be used alone or in parallel with the equipment grounding provided with the single conductor cables to provide the equipment grounding path required by 300.5(I) and 250.118.

If single Type MC conductors are installed in parallel, the equipment grounding path provided with each conductor must be sized on the basis of the ampere rating of the over-current device protecting the circuit conductors according to 250.122(F) and Table 250.122.

#### 330.112 Insulation

Insulated conductors shall comply with 330.112(A) or (B).

**(A) 600 Volts.** Insulated conductors in sizes 18 AWG and 16 AWG shall be of a type listed in Table 402.3, with a maximum operating temperature not less than 90°C (194°F) and as permitted by 725.49. Conductors larger than 16 AWG shall be of a type listed in Table 310.104(A) or of a type identified for use in Type MC cable.

**(B) Over 600 Volts.** Insulated conductors shall be of a type listed in Table 310.104(C) through Table 310.104(E).

#### 330.116 Sheath

Metallic covering shall be one of the following types: smooth metallic sheath, corrugated metallic sheath, interlocking metal tape armor. The metallic sheath shall be continuous and close fitting. A nonmagnetic sheath or armor shall be used on single conductor Type MC. Supplemental protection of an outer covering of corrosion-resistant material shall be permitted and shall be required where such protection is needed. The sheath shall not be used as a current-carrying conductor.

Informational Note: See 300.6 for protection against corrosion.

#### I. General

##### 332.1 Scope

This article covers the use, installation, and construction specifications for mineral-insulated, metal-sheathed cable, Type MI.

Type MI mineral-insulated, metal-sheathed cable consists of one or more solid copper conductors insulated with highly compressed magnesium oxide and enclosed in a continuous copper or alloy steel (e.g., stainless steel) sheath with or without a nonmetallic jacket. It is manufactured in size 16 AWG to 500 kcmil, single conductor; 16 AWG to 4 AWG, 2 and 3 conductor; 16 AWG to 6 AWG, four conductor; and 16 AWG to 10 AWG, 7 conductor. The cable is rated 600 volts.

##### 332.2 Definition

**Mineral-Insulated, Metal-Sheathed Cable, Type MI.** A factory assembly of one or more conductors insulated with a

highly compressed refractory mineral insulation and enclosed in a liquidtight and gastight continuous copper or alloy steel sheath.

#### II. Installation

##### 332.10 Uses Permitted

Type MI cable shall be permitted as follows:

- (1) For services, feeders, and branch circuits
- (2) For power, lighting, control, and signal circuits

Type MI cable is also constructed with a 300-volt rating for signal circuit applications.

- (3) In dry, wet, or continuously moist locations
- (4) Indoors or outdoors
- (5) Where exposed or concealed
- (6) Where embedded in plaster, concrete, fill, or other masonry, whether above or below grade
- (7) In hazardous (classified) locations where specifically permitted by other articles in this Code
- (8) Where exposed to oil and gasoline
- (9) Where exposed to corrosive conditions not deteriorating to its sheath
- (10) In underground runs where suitably protected against physical damage and corrosive conditions
- (11) In or attached to cable tray

Informational Note: The “Uses Permitted” is not an all-inclusive list.

##### 332.12 Uses Not Permitted

Type MI cable shall not be used under the following conditions or in the following locations:

- (1) In underground runs unless protected from physical damage, where necessary
- (2) Where exposed to conditions that are destructive and corrosive to the metallic sheath, unless additional protection is provided

##### 332.17 Through or Parallel to Framing Members

Type MI cable shall be protected in accordance with 300.4 where installed through or parallel to framing members.

##### 332.24 Bending Radius

Bends in Type MI cable shall be so made that the cable will not be damaged. The radius of the inner edge of any bend shall not be less than required as follows:

- (1) Five times the external diameter of the metallic sheath for cable not more than 19 mm (¾ in.) in external diameter

- (2) Ten times the external diameter of the metallic sheath for cable greater than 19 mm ( $\frac{3}{4}$  in.) but not more than 25 mm (1 in.) in external diameter

The minimum bending radius is intended to prevent mechanical damage to the conductor insulation or the sheath that could result in cracking, a hot spot at the point of damage, or both. As illustrated in Exhibit 332.1, for cables with an external or outside diameter (OD) not greater than  $\frac{3}{4}$  in., the minimum bending radius ( $R_{min.}$ ) is 5 times the cable OD. For cables greater than  $\frac{3}{4}$  in. but not greater than 1 in. in diameter, the minimum bending radius is 10 times the cable OD.

**EXHIBIT 332.1** An illustration of 332.24, for bends in Type MI cable.

### 332.30 Securing and Supporting

Type MI cable shall be supported and secured by staples, straps, hangers, or similar fittings, designed and installed so as not to damage the cable, at intervals not exceeding 1.8 m (6 ft).

For support requirements of vertical runs of fire-rated cable assemblies, see 300.19(B), including the associated commentary. Generally, the manufacturer's instructions (to achieve the desired fire rating) require more supports than for non-fire-rated installations.

**(A) Horizontal Runs Through Holes and Notches.** In other than vertical runs, cables installed in accordance with 300.4 shall be considered supported and secured where such support does not exceed 1.8 m (6 ft) intervals.

**(B) Unsupported Cable.** Type MI cable shall be permitted to be unsupported where the cable is fished between access

points through concealed spaces in finished buildings or structures and supporting is impracticable.

**(C) Cable Trays.** All MI cable installed in cable trays shall comply with 392.30(A).

### 332.31 Single Conductors

Where single-conductor cables are used, all phase conductors and, where used, the neutral conductor shall be grouped together to minimize induced voltage on the sheath.

Section 332.31 permits Type MI cables to be used as single conductors. The larger sizes of Type MI cable are available only as single-conductor cables. Because single conductors in a metal sheath can result in induced voltage on the sheath, this section requires all conductors of the circuit to be grouped together to minimize the voltage on the sheath.

Where single conductors enter a ferrous metal enclosure, inductive heating can occur due to hysteresis loss caused by the magnetic flux occurring in ferrous metals and  $I^2R$  losses from the currents induced by the conductor. To minimize this magnetic heating of enclosures, 300.20 requires additional measures, including cutting slots in the metal between the individual holes for each conductor connector. Cable manufacturers offer nonferrous connecting plates that accept individual threaded connections of all circuit conductors, thereby eliminating circulating currents and fully complying with 300.20.

### 332.40 Boxes and Fittings

**(A) Fittings.** Fittings used for connecting Type MI cable to boxes, cabinets, or other equipment shall be identified for such use.

Terminations specifically investigated for use with this cable are listed as "mineral-insulated cable fittings." Fittings for use on Type MI cable are suitable for use at a maximum operating temperature of 90°C in dry locations and 60°C in wet locations. As shown in Exhibit 332.2, a complete box connector consists of a connector body and a screw-on potting fitting that may be used separately as an end fitting for change to open wiring. The screw-on potting fitting is assembled with a special tool and consists of a screw-on pot, insulating cap, insulating sleeving, anchoring bead, and sealing compound.

**(B) Terminal Seals.** Where Type MI cable terminates, an end seal fitting shall be installed immediately after stripping to prevent the entrance of moisture into the insulation. The

conductors extending beyond the sheath shall be individually provided with an insulating material.

### 332.80 Ampacity

The ampacity of Type MI cable shall be determined in accordance with 310.15. The conductor temperature at the end seal fitting shall not exceed the temperature rating of the listed end seal fitting, and the installation shall not exceed the temperature ratings of terminations or equipment.

**(A) Type MI Cable Installed in Cable Tray.** The ampacities for Type MI cable installed in cable tray shall be determined in accordance with 392.80(A).

**(B) Single Type MI Conductors Grouped Together.** Where single Type MI conductors are grouped together in a triangular or square configuration, as required by 332.31, and installed on a messenger or exposed with a maintained free air space of not less than 2.15 times one conductor diameter ( $2.15 \times \text{O.D.}$ ) of the largest conductor contained within the configuration and adjacent conductor configurations or cables, the ampacity of the conductors shall not exceed the allowable ampacities of Table 310.15(B)(17).

Using Table 310.15(B)(16) or Table 310.15(B)(17) is the most common approach to determining the ampacities specified in 332.80(B). However, where MI cables are terminated at distribution and control equipment, such as circuit breakers, switchgear, and transfer switches, the temperature limitations of electrical equipment terminals must be coordinated with the ampacity of the MI cables. As stated in both the *UL Guide Information for Electrical Equipment — The White Book-2010* and in 110.14(C)(1), unless equipment is listed and marked otherwise, conductor ampacities used in determining equipment terminations must be based on Table 310.15(B)(16) as appropriately modified by 310.15(B)(7). Where MI cable is constructed using nickel conductors or

nickel-coated copper conductors, the allowable ampacities of Tables 310.15(B)(16) through 310.15(B)(18) do not apply, and the product manufacturer must be consulted for proper ampacities.

## III. Construction Specifications

### 332.104 Conductors

Type MI cable conductors shall be of solid copper, nickel, or nickel-coated copper with a resistance corresponding to standard AWG and kcmil sizes.

### 332.108 Equipment Grounding Conductor

Where the outer sheath is made of copper, it shall provide an adequate path to serve as an equipment grounding conductor. Where the outer sheath is made of steel, a separate equipment grounding conductor shall be provided.

The copper sheath of Type MI cable is permitted as an equipment grounding conductor according to 250.118(10), but an alloy steel outer sheath of Type MI cable is not. According to the product standard, for Type MI cables with an alloy steel outer sheath, one of the conductors (within the cable assembly) must be used for equipment grounding. This is in concert with the requirement of 300.3, which prohibits the installation of single conductors unless they are part of a wiring method of Chapter 3 of the *Code*. The size of an equipment grounding conductor is determined according to 250.122. If an individual equipment grounding conductor is installed with a multiconductor Type MI cable installation, the separate equipment grounding conductor must be an integral part of the multiconductor Type MI cable, rather than a separate conductor.

If single Type MI conductors are installed as open runs or as messenger-supported wiring, the copper sheath on each

**EXHIBIT 332.2** A Type MI cable fitting used for terminating cable to an enclosure, to a box, or directly to equipment. (Courtesy of Tyco Thermal Controls)

conductor must have sufficient cross-sectional area to comply with Table 250.122.

If single Type MI conductors are installed in cable tray, the cable tray, an equipment grounding conductor(s) within the cable tray, and/or the equipment grounding provided with the single conductor may be used individually or in any parallel combination to provide the equipment grounding path according to the requirements of 392.60(A) and 250.118.

If single Type MI conductors are installed underground in a trench, a separate equipment grounding conductor may be installed in close proximity to the circuit conductors within the same trench. The separate equipment grounding conductor may be used alone or in parallel with the equipment grounding provided with the single conductor to provide the equipment grounding path required by 300.5(I) and 250.118.

If single Type MI conductors are installed in parallel, the equipment grounding path provided with each conductor must be sized on the basis of the ampere rating of the over-current device protecting the circuit conductors in accordance with 250.122(F).

### 332.112 Insulation

The conductor insulation in Type MI cable shall be a highly compressed refractory mineral that provides proper spacing for all conductors.

### 332.116 Sheath

The outer sheath shall be of a continuous construction to provide mechanical protection and moisture seal.

## I. General

### 334.1 Scope

This article covers the use, installation, and construction specifications of nonmetallic-sheathed cable.

### 334.2 Definitions

**Nonmetallic-Sheathed Cable.** A factory assembly of two or more insulated conductors enclosed within an overall nonmetallic jacket.

**Type NM.** Insulated conductors enclosed within an overall nonmetallic jacket.

**Type NMC.** Insulated conductors enclosed within an overall, corrosion resistant, nonmetallic jacket.

**Type NMS.** Insulated power or control conductors with signaling, data, and communications conductors within an overall nonmetallic jacket.

Types NM, NMC, and NMS nonmetallic-sheathed cable may be used for either exposed or concealed wiring. Where exposed, the cable should not be subject to physical damage.

Nonmetallic-sheathed cable was first recognized in the 1928 *NEC* as a substitute for concealed knob-and-tube wiring (Article 394) and open wiring on insulators (Article 398). The original advantages of nonmetallic-sheathed cable over knob-and-tube wiring were that the outer sheath provided continuous protection in addition to the insulation applied to the conductors; the cable was easily fished in partitions of finished buildings; no insulating supports were required; and only one hole need be bored that could accommodate more than one cable passing through a wood cross member.

### 334.6 Listed

Type NM, Type NMC, and Type NMS cables shall be listed.

Nonmetallic-sheathed cables must be listed. UL 719, *Standard for Nonmetallic-Sheathed Cables*, requires a construction and performance evaluation, including testing related to flammability, dielectric voltage-withstand, unwinding at low temperatures, pulling through joists, conductor pullout, crushing, and abrasion.

## II. Installation

### 334.10 Uses Permitted

Type NM, Type NMC, and Type NMS cables shall be permitted to be used in the following:

- (1) One- and two-family dwellings and their attached or detached garages, and their storage buildings.

This section was revised for the 2011 *Code* to clarify that the requirements for the use of nonmetallic-sheathed cable in garages of one- and two-family dwellings apply regardless of whether the garage is attached or detached. The same requirements also apply to detached sheds or storage buildings associated with one- and two-family dwellings.

- (2) Multifamily dwellings permitted to be of Types III, IV, and V construction except as prohibited in 334.12.
- (3) Other structures permitted to be of Types III, IV, and V construction except as prohibited in 334.12. Cables shall be concealed within walls, floors, or ceilings that provide a thermal barrier of material that has at least a 15-minute finish rating as identified in listings of fire-rated assemblies.

Informational Note No. 1: Types of building construction and occupancy classifications are defined in NFPA 220-2009, *Standard on Types of Building Construction*, or the applicable building code, or both.

Informational Note No. 2: See Informative Annex E for determination of building types [NFPA 220, Table 3-1].

- (4) Cable trays in structures permitted to be Types III, IV, or V where the cables are identified for the use.

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

- (5) Types I and II construction where installed within raceways permitted to be installed in Types I and II construction.

A well-established means of codifying fire protection and fire safety requirements is to classify buildings by types of construction, based on materials used for the structural elements and the degree of fire resistance afforded by each element. The five fundamental construction types used by the model building codes are Type I (fire resistive), Type II (noncombustible), Type III (combination of combustible and noncombustible), Type IV (heavy timber), and Type V (wood frame). Types I and II basically require all structural elements to be noncombustible, whereas Types III, IV, and V allow some or all of the structural elements to be combustible (wood).

The selection of building construction types is regulated by the local building code, based on the occupancy, height, and area of the building. When a building of a selected height (in feet or stories above grade) and area is permitted to be built of combustible construction (i.e., Types III, IV, or V), the installation of nonmetallic-sheathed cable is permitted. The common areas (corridors) and incidental and subordinate uses (laundry rooms, lounge rooms, etc.) that serve a multifamily dwelling occupancy are also considered part of the multifamily occupancy, thereby allowing the use of nonmetallic-sheathed cable in those areas.

If a building is to be of noncombustible construction (i.e., Type I or II) by the owner's choice, even though the building code would permit combustible construction, the building is allowed to be wired with nonmetallic-sheathed cable. In such an instance, nonmetallic-sheathed cable may be installed in the noncombustible building because the *Code* would have permitted the building to be of combustible construction.

As indicated in Informational Note No. 2, Informative Annex E provides information on the types of construction, as well as a table that cross references the five construction types to the types described in the model building codes.

Section 334.10(5), which was previously in 334.10(A)(1), Exception, permits Type NM, nonmetallic-sheathed cables to be installed in Type I and Type II construction if the cables are within *permitted* raceways. A raceway is only permitted to be used if it complies with the article for the raceway and its use does not violate another article in the code.

**(A) Type NM.** Type NM cable shall be permitted as follows:

- (1) For both exposed and concealed work in normally dry locations except as prohibited in 334.10(3)
- (2) To be installed or fished in air voids in masonry block or tile walls

For concealed work, nonmetallic-sheathed cable should be installed where it is protected from physical damage often caused by nails or screws. Where practical, care should be taken to avoid areas where trim, door and window casings, baseboards, moldings, and so on, are likely to be nailed. See 300.4 for details on protection against physical damage.

**(B) Type NMC.** Type NMC cable shall be permitted as follows:

- (1) For both exposed and concealed work in dry, moist, damp, or corrosive locations, except as prohibited by 334.10(3)
- (2) In outside and inside walls of masonry block or tile
- (3) In a shallow chase in masonry, concrete, or adobe protected against nails or screws by a steel plate at least 1.59 mm ( $\frac{1}{16}$  in.) thick and covered with plaster, adobe, or similar finish

Type NMC (corrosion-resistant) cable is required for installation in dairy barns and similar farm buildings (see Article 547), where cable will be exposed to fumes, vapors, or liquids such as ammonia and barnyard acids. Under such circumstances, ordinary types of nonmetallic-sheathed cable have in some cases deteriorated rapidly due to ammonia fumes or the growth of fungus or mold.

In addition to insulated conductors, nonmetallic-sheathed cable must have an insulated or bare conductor for equipment grounding purposes only, in order to comply with 334.108. See 250.119 and Table 250.122 for identification requirements and minimum conductor sizes.

**(C) Type NMS.** Type NMS cable shall be permitted as follows:

- (1) For both exposed and concealed work in normally dry locations except as prohibited by 334.10(3)
- (2) To be installed or fished in air voids in masonry block or tile walls

### 334.12 Uses Not Permitted

The list of uses not permitted for Type NM cable given in 334.12 is not complete. Restrictions exist elsewhere in the code. For example, Type NM, nonmetallic-sheathed cables

are not permitted to be installed in ducts, plenums, and other air-handling spaces. See 300.22, which limits the use of materials in ducts, plenums, and other air-handling spaces that may contribute smoke and products of combustion during a fire.

**(A) Types NM, NMC, and NMS.** Types NM, NMC, and NMS cables shall not be permitted as follows:

- (1) In any dwelling or structure not specifically permitted in 334.10(1), (2), and (3)
- (2) Exposed in dropped or suspended ceilings in other than one- and two-family and multifamily dwellings

Section 334.12(A)(2) prohibits nonmetallic-sheathed cables installed as exposed in the space above accessible hung ceilings. This requirement does not affect dwelling-type occupancies. The term *exposed*, as used in this requirement, closely follows the definition of *exposed (as applied to wiring methods)* found in Article 100, which states “on or attached to the surface or behind panels designed to allow access.”

For example, cables installed above a dropped gypsum board ceiling or dropped gypsum board soffit would not be considered exposed cable, provided the area above the ceiling is not accessible (does not have removable tiles or does not contain an access panel). Very often, hung or dropped ceilings are accessible; therefore, cables installed above these types of ceilings would be considered exposed cables if the cables do not have additional physical protection.

Additionally, a simple change to an architectural finish schedule during construction could change the acceptability of the wiring method. For example, if a corridor ceiling in an occupancy (other than a dwelling type) called for a painted gypsum board ceiling and the finish schedule changed the ceiling construction to a 2 ft × 2 ft accessible tile ceiling, the wiring method would no longer be permitted to be nonmetallic-sheathed cable unless the nonmetallic-sheathed cable was installed using additional protection. Examples of additional protection are found in 334.15(B).

- (3) As service-entrance cable
- (4) In commercial garages having hazardous (classified) locations as defined in 511.3
- (5) In theaters and similar locations, except where permitted in 518.4(B)
- (6) In motion picture studios
- (7) In storage battery rooms
- (8) In hoistways or on elevators or escalators
- (9) Embedded in poured cement, concrete, or aggregate
- (10) In hazardous (classified) locations, except where specifically permitted by other articles in this Code.

**(B) Types NM and NMS.** Types NM and NMS cables shall not be used under the following conditions or in the following locations:

- (1) Where exposed to corrosive fumes or vapors
- (2) Where embedded in masonry, concrete, adobe, fill, or plaster
- (3) In a shallow chase in masonry, concrete, or adobe and covered with plaster, adobe, or similar finish
- (4) In wet or damp locations

### 334.15 Exposed Work

In exposed work, except as provided in 300.11(A), cable shall be installed as specified in 334.15(A) through (C).

**(A) To Follow Surface.** Cable shall closely follow the surface of the building finish or of running boards.

**(B) Protection from Physical Damage.** Cable shall be protected from physical damage where necessary by rigid metal conduit, intermediate metal conduit, electrical metallic tubing, Schedule 80 PVC conduit, **Type RTRC marked with the suffix -XW**, or other approved means. Where passing through a floor, the cable shall be enclosed in rigid metal conduit, intermediate metal conduit, electrical metallic tubing, Schedule 80 PVC conduit, **Type RTRC marked with the suffix -XW**, or other approved means extending at least 150 mm (6 in.) above the floor.

Type NMC cable installed in shallow chases or grooves in masonry, concrete, or adobe shall be protected in accordance with the requirements in 300.4(F) and covered with plaster, adobe, or similar finish.

This section was revised for the 2011 *Code* to recognize Type RTRC-XW conduit as a means to provide nonmetallic-sheathed cable with protection from physical damage.

**(C) In Unfinished Basements and Crawl Spaces.** Where cable is run at angles with joists in unfinished basements and crawl spaces, it shall be permissible to secure cables not smaller than two 6 AWG or three 8 AWG conductors directly to the lower edges of the joists. Smaller cables shall be run either through bored holes in joists or on running boards. **Nonmetallic-sheathed** cable installed on the wall of an unfinished basement shall be permitted to be installed in a listed conduit or tubing or shall be protected in accordance with 300.4. Conduit or tubing shall be provided with a suitable insulating bushing or adapter at the point the cable enters the raceway. The **sheath of the nonmetallic-sheathed cable** shall extend through the conduit or tubing and into the outlet or device box not less than 6 mm (¼ in.). The cable

shall be secured within 300 mm (12 in.) of the point where the cable enters the conduit or tubing. Metal conduit, tubing, and metal outlet boxes shall be connected to an equipment grounding conductor **complying with the provisions of 250.86 and 250.148.**

Crawl spaces pose dangers similar to those of unfinished basements and in some case are more dangerous due to limited height. The means of providing physical protection in crawl spaces and unfinished basements includes specific protection techniques. Type PVC, Schedule 40 is omitted from this list unless it is judged as an “approved” means by the authority having jurisdiction. Also, where NMC is installed close to the surface in masonry, concrete, or adobe-type construction, physical protection must be afforded to the cable by using steel plate-type protectors as described in 300.4(F).

Nonmetallic-sheathed cables installed in an unfinished basement or crawl space can be run through holes in joists, attached to the side of joists or beams, and installed on running boards as shown on the left side in Exhibit 334.1. Section 300.4(D) requires cables that run parallel to framing members be installed at least 1¼ in. from the nearest edge of studs, joists, or rafters.

### 334.17 Through or Parallel to Framing Members

Types NM, NMC, or NMS cable shall be protected in accordance with 300.4 where installed through or parallel to framing members. Grommets used as required in 300.4(B)(1) shall remain in place and be listed for the purpose of cable protection.

Cable that passes through factory- or field-punched holes in metal studs or similar members is required by 334.17 to be protected in accordance with 300.4(B)(1). Listed bushings or listed grommets covering all metal edges must be securely fastened in the opening before the cable is installed. See the commentary following 300.4(B)(1) for further information regarding physical protection of NM cables.

### 334.23 In Accessible Attics

The installation of cable in accessible attics or roof spaces shall also comply with 320.23.

### 334.24 Bending Radius

Bends in Types NM, NMC, and NMS cable shall be so made that the cable will not be damaged. The radius of the curve

**EXHIBIT 334.1** Nonmetallic-sheathed cables and Type SE cables installed in an unfinished basement or crawl space in accordance with 334.15(C).

of the inner edge of any bend during or after installation shall not be less than five times the diameter of the cable.

### 334.30 Securing and Supporting

Nonmetallic-sheathed cable shall be supported and secured by staples, cable ties, straps, hangers, or similar fittings designed and installed so as not to damage the cable, at intervals not exceeding 1.4 m (4½ ft) and within 300 mm (12 in.) of every outlet box, junction box, cabinet, or fitting. Flat cables shall not be stapled on edge.

Sections of cable protected from physical damage by raceway shall not be required to be secured within the raceway.

The general requirement of 334.30 is that the cable be secured. Simply draping the cable over air ducts, rafters, timbers, joists, pipes, and ceiling grid members is not permitted, except where fished as allowed in 334.30(B)(1).

Section 334.30 also prohibits two-conductor nonmetallic-sheathed cable (or other flat configurations) from being stapled on edge. The intent is to prohibit the cable from being installed with its short dimension against a wood joist. When stapled in this manner, two cables are usually placed side by side under the staple. If the staple is driven too far into the stud, damage to the insulation and conductors could occur. See 300.4(C) for support requirements of cables through spaces behind panels designed to allow access.

**(A) Horizontal Runs Through Holes and Notches.** In other than vertical runs, cables installed in accordance with 300.4 shall be considered to be supported and secured where such support does not exceed 1.4-m (4½-ft) intervals and the nonmetallic-sheathed cable is securely fastened in place by an approved means within 300 mm (12 in.) of each box,

cabinet, conduit body, or other nonmetallic-sheathed cable termination.

Informational Note: See 314.17(C) for support where non-metallic boxes are used.

Section 334.30(A) considers nonmetallic-sheathed cable running horizontally through framing members (spaced less than 54 in. apart) and passing through bored or punched holes in the framing members to be supported by the framing members and does not require additional securing or fastening with cable ties. However, the nonmetallic-sheathed cable must be secured within 12 in. of the outlet box. Where the cable terminates at a nonmetallic outlet box that does not contain a cable clamping device, the cable may be secured (fastened in place) within 8 in. of the outlet box, according to 314.17(C), Exception.

**(B) Unsupported Cables.** Nonmetallic-sheathed cable shall be permitted to be unsupported where the cable:

- (1) Is fished between access points through concealed spaces in finished buildings or structures and supporting is impracticable.
- (2) Is not more than 1.4 m (4½ ft) from the last point of cable support to the point of connection to a luminaire or other piece of electrical equipment and the cable and point of connection are within an accessible ceiling.

Section 334.30(B)(2) permits short, unsupported lengths of nonmetallic-sheathed cable for luminaire and equipment connections.

**(C) Wiring Device Without a Separate Outlet Box.** A wiring device identified for the use, without a separate outlet

box, and incorporating an integral cable clamp shall be permitted where the cable is secured in place at intervals not exceeding 1.4 m (4½ ft) and within 300 mm (12 in.) from the wiring device wall opening, and there shall be at least a 300 mm (12 in.) loop of unbroken cable or 150 mm (6 in.) of a cable end available on the interior side of the finished wall to permit replacement.

### 334.40 Boxes and Fittings

**(A) Boxes of Insulating Material.** Nonmetallic outlet boxes shall be permitted as provided by 314.3.

Nonmetallic boxes and nonmetallic wiring systems are recommended for use in some corrosive atmospheres, such as farm buildings. See Article 547 for details.

**(B) Devices of Insulating Material.** Switch, outlet, and tap devices of insulating material shall be permitted to be used without boxes in exposed cable wiring and for rewiring in existing buildings where the cable is concealed and fished. Openings in such devices shall form a close fit around the outer covering of the cable, and the device shall fully enclose the part of the cable from which any part of the covering has been removed. Where connections to conductors are by binding-screw terminals, there shall be available as many terminals as conductors.

**(C) Devices with Integral Enclosures.** Wiring devices with integral enclosures identified for such use shall be permitted as provided by 300.15(E).

### 334.80 Ampacity

The ampacity of Types NM, NMC, and NMS cable shall be determined in accordance with 310.15. The allowable ampacity shall not exceed that of a 60°C (140°F) rated conductor. The 90°C (194°F) rating shall be permitted to be used for ampacity adjustment and correction calculations, provided the final derated ampacity does not exceed that of a 60°C (140°F) rated conductor. The ampacity of Types NM, NMC, and NMS cable installed in cable tray shall be determined in accordance with 392.80(A).

Where more than two NM cables containing two or more current-carrying conductors are installed, without maintaining spacing between the cables, through the same opening in wood framing that is to be sealed with thermal insulation, caulk, or sealing foam, the allowable ampacity of each conductor shall be adjusted in accordance with Table 310.15(B)(3)(a) and the provisions of 310.15(A)(2), Exception, shall not apply.

Where more than two NM cables containing two or more current-carrying conductors are installed in contact

with thermal insulation without maintaining spacing between cables, the allowable ampacity of each conductor shall be adjusted in accordance with Table 310.15(B)(3)(a).

Section 334.80 references 310.15 for determining the ampacities of Types NM, NMC, and NMS cable. As stated in 310.15(B)(3)(a): “. . . where single conductors or multiconductor cables are installed without maintaining spacing for a continuous length longer than 600 mm (24 in.) and are not installed in raceways, the allowable ampacity of each conductor shall be reduced as shown in Table 310.15(B)(3)(a).” Failure to apply the appropriate ampacity adjustment factor called for by this table, where nonmetallic-sheathed cables are stacked or bundled without maintaining spacing, can lead to overheating of conductors. The ampacity adjustment requirements prevent overheating of Type NM conductors where passing through wood-framed draft- and fire-stopping material. The ampacity adjustment requirement for installations of more than two cables that are in direct contact with thermal insulation is intended to prevent overheating of Type NM conductors. Not only is thermal insulation provided within structures to reduce heat loss or heat gain, but the same thermal insulation material may be used to control sound within structures as well.

#### Calculation Example

Four 2-conductor, size 12 AWG, copper with ground, Type NM cables are installed in direct contact with thermal insulation according to the requirements of 334.80. Calculate the ampacity of the conductors and determine the maximum overcurrent protection permitted for these four circuits.

#### Solution

STEP 1. Determine the number of current-carrying conductors. According to 310.15(B)(3)(a), the number of current-carrying conductors is

$$4 \text{ cables} \times 2 \text{ conductors per cable} = 8 \text{ current-carrying conductors}$$

STEP 2. Determine the initial ampacity of 12 AWG using 334.80 and Table 310.15(B)(16). Using the 90°C copper ampacity from Table 310.15(B)(16) for derating purposes, the ampacity (prior to derating) is 30 amperes.

STEP 3. Determine the adjusted ampacity of each NM cable due to direct contact with thermal insulation using Table 310.15(B)(3)(a), eight current-carrying conductors require an adjustment factor of 70 percent:

$$30 \text{ amperes} \times 70\% \text{ adjustment factor} \\ 30 \text{ amperes} \times 0.7 = 21 \text{ adjusted amperes}$$

STEP 4. Determine the maximum permitted overcurrent device for each NM cable circuit in this example. Section

334.80 does not allow an ampacity greater than given in the 60°C column of Table 310.15(B)(16). And, according to the footnote of Table 310.15(B)(16), conductor sizes of 14 AWG through 10 AWG must also comply with 240.4(D). Section 240.4(D) limits a 12 AWG copper conductor to a maximum of 20 amperes. Therefore, the 21 amperes of adjusted ampacity must be further reduced or limited by being protected by an overcurrent device not to exceed 20 amperes.

Thus, 20 amperes is the final ampacity for each current-carrying conductor of this problem, and the maximum overcurrent device permitted for each of the four circuits in NM cable is 20 amperes.

**Conclusion:** This example points out that NM cable can be installed without spacing and placed within thermal insulation by not exceeding nine current-carrying conductors [70 percent adjustment factor of Table 310.15(B)(3)(a)]. By following similar installation practice as outlined in this example, this requirement will have little impact on most installations, whether installing groups of NM cable from panelboards or installing multiple NM cables down to ganged switches, as long as the quantity is limited to not more than nine current-carrying conductors.

### III. Construction Specifications

#### 334.100 Construction

The outer cable sheath of nonmetallic-sheathed cable shall be a nonmetallic material.

#### 334.104 Conductors

The 600-volt insulated conductors shall be sizes 14 AWG through 2 AWG copper conductors or sizes 12 AWG through 2 AWG aluminum or copper-clad aluminum conductors. The communications conductors shall comply with Part V of Article 800.

#### 334.108 Equipment Grounding Conductor

In addition to the insulated conductors, the cable shall have an insulated, covered, or bare equipment grounding conductor.

The equipment grounding conductor required by 334.108 must be sized in accordance with 250.122 and comply with UL 719, *Standard for Nonmetallic-Sheathed Cables*.

#### 334.112 Insulation

The insulated power conductors shall be one of the types listed in Table 310.104(A) that are suitable for branch-circuit wiring or one that is identified for use in these cables. Conductor insulation shall be rated at 90°C (194°F).

**Informational Note:** Types NM, NMC, and NMS cable identified by the markings NM-B, NMC-B, and NMS-B meet this requirement.

#### 334.116 Sheath

The outer sheath of nonmetallic-sheathed cable shall comply with 334.116(A), (B), and (C).

**(A) Type NM.** The overall covering shall be flame retardant and moisture resistant.

**(B) Type NMC.** The overall covering shall be flame retardant, moisture resistant, fungus resistant, and corrosion resistant.

**(C) Type NMS.** The overall covering shall be flame retardant and moisture resistant. The sheath shall be applied so as to separate the power conductors from the communications conductors.

    - (C) Class 1 Circuit Conductors
  - 336.116 Jacket
  - 336.120 Marking

### I. General

#### 336.1 Scope

This article covers the use, installation, and construction specifications for power and control tray cable, Type TC.

The basic standard to investigate products in this category is UL 1277, *Electrical Power and Control Tray Cables with*

*Optional Optical-Fiber Members.* Summary information regarding listed power and control tray cable may be found in the *UL Guide Information for Electrical Equipment — The White Book-2010*, under category QPOR.

### 336.2 Definition

**Power and Control Tray Cable, Type TC.** A factory assembly of two or more insulated conductors, with or without associated bare or covered grounding conductors, under a nonmetallic jacket.

## II. Installation

Section 336.10(6) permits Type TC tray cable to be used for non-power-limited fire alarm circuits. According to 760.49, the cable must be listed and the conductor material must be copper. Aluminum and copper-clad aluminum conductors are not permitted for fire alarm circuits.

According to 336.10(7), specific types of TC tray cable used in qualifying occupancies are permitted to extend from a cable tray to a piece of equipment without the use of conduit. According to UL 1277, *Electrical Power and Control Tray Cables with Optional Optical-Fiber Members*, cables suitable for use as exposed wiring between cable tray and the utilization equipment according to 336.10(7) are surface-marked "Type TC-ER" (tray cable for exposed runs).

The exception to 336.10(7) permits TC-ER cable to properly exit cable tray without continuous support for a limit of 6 ft. However, the exception clearly does not allow extension from cable tray to cable tray or from cable tray to equipment beyond 6 ft without continuous support.

### 336.10 Uses Permitted

Type TC cable shall be permitted to be used as follows:

- (1) For power, lighting, control, and signal circuits.
- (2) In cable trays.
- (3) In raceways.
- (4) In outdoor locations supported by a messenger wire.
- (5) For Class 1 circuits as permitted in Parts II and III of Article 725.
- (6) For non-power-limited fire alarm circuits if conductors comply with the requirements of 760.49.
- (7) In industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation, and where the cable is continuously supported and protected against physical damage using mechanical protection, such as struts, angles, or channels, Type TC tray cable that complies with the crush and impact requirements of Type MC cable and is identified for such use with the marking

Type TC-ER shall be permitted between a cable tray and the utilization equipment or device. The cable shall be secured at intervals not exceeding 1.8 m (6 ft). Equipment grounding for the utilization equipment shall be provided by an equipment grounding conductor within the cable. In cables containing conductors sized 6 AWG or smaller, the equipment grounding conductor shall be provided within the cable or, at the time of installation, one or more insulated conductors shall be permanently identified as an equipment grounding conductor in accordance with 250.119(B).

*Exception: Where not subject to physical damage, Type TC-ER shall be permitted to transition between cable trays and between cable trays and utilization equipment or devices for a distance not to exceed 1.8 m (6 ft) without continuous support. The cable shall be mechanically supported where exiting the cable tray to ensure that the minimum bending radius is not exceeded.*

- (8) Where installed in wet locations, Type TC cable shall also be resistant to moisture and corrosive agents.

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

### 336.12 Uses Not Permitted

Type TC tray cable shall not be installed or used as follows:

- (1) Installed where it will be exposed to physical damage
- (2) Installed outside a raceway or cable tray system, except as permitted in 336.10(4) and 336.10(7)
- (3) Used where exposed to direct rays of the sun, unless identified as sunlight resistant
- (4) Direct buried, unless identified for such use

### 336.24 Bending Radius

Bends in Type TC cable shall be made so as not to damage the cable. For Type TC cable without metal shielding, the minimum bending radius shall be as follows:

- (1) Four times the overall diameter for cables 25 mm (1 in.) or less in diameter
- (2) Five times the overall diameter for cables larger than 25 mm (1 in.) but not more than 50 mm (2 in.) in diameter
- (3) Six times the overall diameter for cables larger than 50 mm (2 in.) in diameter

Type TC cables with metallic shielding shall have a minimum bending radius of not less than 12 times the cable overall diameter.

### 336.80 Ampacity

The ampacity of Type TC tray cable shall be determined in accordance with 392.80(A) for 14 AWG and larger conduc-

tors, in accordance with 402.5 for 18 AWG through 16 AWG conductors where installed in cable tray, and in accordance with 310.15 where installed in a raceway or as messenger-supported wiring.

### III. Construction Specifications

#### 336.100 Construction

A metallic sheath or armor as defined in 330.116 shall not be permitted either under or over the nonmetallic jacket. Metallic shield(s) shall be permitted over groups of conductors, under the outer jacket, or both.

Type TC cables are permitted by 336.100 to have one or more metal shields, but not a metal sheath or armor. Electrical cables with a metal sheath or armor are covered in either Article 320 as armored cable, Type AC, or Article 330 as metal-clad cable, Type MC.

#### 336.104 Conductors

The insulated conductors of Type TC cables shall be in sizes 18 AWG to 1000 kcmil copper, nickel, or nickel-coated copper, and sizes 12 AWG through 1000 kcmil aluminum or copper-clad aluminum. Insulated conductors of sizes 14 AWG, and larger copper, nickel, or nickel-coated copper, and sizes 12 AWG through 1000 kcmil aluminum or copper-clad aluminum shall be one of the types listed in Table 310.104(A) or Table 310.104(B) that is suitable for branch circuit and feeder circuits or one that is identified for such use.

Section 336.104 permits Type TC cables to be constructed using nickel or nickel-coated conductors. The use of nickel and nickel-coated copper conductor material is generally permitted by 310.106(B) and shown in Table 310.104(A) for insulation types PFAH and TFE (and used in high-temperature applications).

**(A) Fire Alarm Systems.** Where used for fire alarm systems, conductors shall also be in accordance with 760.49.

**(B) Thermocouple Circuits.** Conductors in Type TC cable used for thermocouple circuits in accordance with Part III of Article 725 shall also be permitted to be any of the materials used for thermocouple extension wire.

**(C) Class 1 Circuit Conductors.** Insulated conductors of 18 AWG and 16 AWG copper shall also be in accordance with 725.49.

#### 336.116 Jacket

The outer jacket shall be a flame-retardant, nonmetallic material.

#### 336.120 Marking

There shall be no voltage marking on a Type TC cable employing thermocouple extension wire.

## ARTICLE 338 Service-Entrance Cable: Types SE and USE

### Contents

- I. General
  - 338.1 Scope
  - 338.2 Definitions
- II. Installation
  - 338.10 Uses Permitted
    - (A) Service-Entrance Conductors
    - (B) Branch Circuits or Feeders
  - 338.12 Uses Not Permitted
    - (A) Service-Entrance Cable
    - (B) Underground Service-Entrance Cable
  - 338.24 Bending Radius
- III. Construction
  - 338.100 Construction
  - 338.120 Marking

### I. General

#### 338.1 Scope

This article covers the use, installation, and construction specifications of service-entrance cable.

According to the *UL Guide Information for Electrical Equipment — The White Book-2010*, category TXKT (service cable) and category TYLZ (service-entrance cable rated 600 volts) are listed in sizes 14 AWG and larger for copper and 12 AWG and larger for aluminum or copper-clad aluminum. Type SE cable contains Types RHW, RHW-2, XHHW, XHHW-2, THWN, or THWN-2 conductors. Type USE cable contains conductors with insulation equivalent to RHW or XHHW. Type USE-2 contains insulation equivalent to RHW-2 or XHHW-2 and is rated 90°C wet or dry.

The type designation of the conductors may be marked on the surface of the cable. When used, this marking indicates the temperature rating for the cable corresponding to the temperature rating of the conductors. When this marking

does not appear, the temperature rating of the cable is 75°C. The cables are designated as Type SE, Type USE or USE-2, and submersible water pump cable.

**Type SE** — Indicates cable for aboveground installation. Both the individual insulated conductors and the outer jacket or finish of Type SE are suitable for use where exposed to sun.

**Type USE or USE-2** — Indicates cable for underground installation, including burial directly in the earth. Cable in sizes 4/0 AWG and smaller and having all conductors insulated is suitable for all of the underground uses for which Type UF cable is permitted by the *Code*. Types USE and USE-2 are not suitable for use in premises or above ground except to terminate at the service equipment or metering equipment. Both the insulation and the outer covering, when used on single and multiconductor Types USE and USE-2, are suitable for use where exposed to sun.

**Submersible water pump cable** — Indicates a multiconductor cable in which two, three, or four single-conductor, Type USE or USE-2 cables are provided in a flat or twisted assembly. The cable is listed in sizes 14 AWG to 4/0 AWG inclusive for copper and 12 AWG to 4/0 AWG inclusive for aluminum or copper-clad aluminum. The cable is tag-marked “For Use Within the Well Casing for Wiring Deep-Well Water Pumps Where the Cable Is Not Subject to Repetitive Handling Caused by Frequent Servicing of the Pump Units.” The insulation may also be surface-marked “Pump Cable.” The cable may be directly buried in the earth in conjunction with this use.

## 338.2 Definitions

**Service-Entrance Cable.** A single conductor or multiconductor assembly provided with or without an overall covering, primarily used for services, and of the following types:

**Type SE.** Service-entrance cable having a flame-retardant, moisture-resistant covering.

**Type USE.** Service-entrance cable, identified for underground use, having a moisture-resistant covering, but not required to have a flame-retardant covering.

## II. Installation

### 338.10 Uses Permitted

**(A) Service-Entrance Conductors.** Service-entrance cable shall be permitted to be used as service-entrance conductors and shall be installed in accordance with 230.6, 230.7, and Parts II, III, and IV of Article 230.

#### **(B) Branch Circuits or Feeders.**

**(1) Grounded Conductor Insulated.** Type SE service-entrance cables shall be permitted in wiring systems where

all of the circuit conductors of the cable are of the thermoset or thermoplastic type.

Branch circuits using service-entrance cable as a wiring method are permitted only if all circuit conductors within the cable are fully insulated according to 310.104. The equipment grounding conductor is the only conductor permitted to be bare or covered within service-entrance cable used for branch circuits.

**(2) Use of Uninsulated Conductor.** Type SE service-entrance cable shall be permitted for use where the insulated conductors are used for circuit wiring and the uninsulated conductor is used only for equipment grounding purposes.

*Exception: In existing installations, uninsulated conductors shall be permitted as a grounded conductor in accordance with 250.32 and 250.140, where the uninsulated grounded conductor of the cable originates in service equipment, and with 225.30 through 225.40.*

In accordance with 338.10(B)(2), service-entrance cable containing a bare grounded (neutral) conductor is not permitted for new installations where it is used as a branch circuit to supply appliances such as ranges, wall-mounted ovens, counter-mounted cooking units, or clothes dryers. The exception to 338.10(B)(2) permits a bare neutral service-entrance cable for existing installations only and is coordinated with the sections listed.

**(3) Temperature Limitations.** Type SE service-entrance cable used to supply appliances shall not be subject to conductor temperatures in excess of the temperature specified for the type of insulation involved.

#### **(4) Installation Methods for Branch Circuits and Feeders.**

**(a) Interior Installations.** In addition to the provisions of this article, Type SE service-entrance cable used for interior wiring shall comply with the installation requirements of Part II of Article 334, excluding 334.80.

Where installed in thermal insulation, the ampacity shall be in accordance with the 60°C (140°F) conductor temperature rating. The maximum conductor temperature rating shall be permitted to be used for ampacity adjustment and correction purposes, if the final derated ampacity does not exceed that for a 60°C (140°F) rated conductor.

Informational Note No. 1: See 310.15(A)(3) for temperature limitation of conductors.

Informational Note No. 2: For the installation of main power feeder conductors in dwelling units refer to 310.15(B)(7).

Section 338.10(B)(4)(a) was revised for the 2011 *Code* to include a requirement that addresses the effect of thermal insulation on conductor ampacity. Type SE cable is permitted as an interior branch circuit or feeder wiring method and where used in this manner, the installation is to comply with the requirements in Part II of Article 334 (Type NM cable) except for the ampacity rules in 334.80. The different configurations of Type SE cable, including SEU and SER, are used for a variety of interior circuits including ranges, clothes dryers, heating, and air-conditioning equipment and as feeders to supply panelboards that are not the service equipment.

While all conductors in nonmetallic-sheathed cable are required to have 90°C-rated insulation, 334.80 limits the operating (calculated load) ampacity to those contained in the 60°C column of Table 310.15(B)(16). This limitation applies to all uses of Type NM cable. In contrast to this restriction on Type NM cable, Type SE cable is only limited to operating at a 60°C ampacity when it is installed in thermal insulation. Type SE cable is permitted to have conductors with either 75°C or 90°C insulation, and any ampacity adjustment or correction has to be based on the temperature rating of the conductors in the specific SE cable. If there is no temperature marking on the surface of the cable, the conductors have a 75°C insulation temperature rating, and ampacity adjustment or correction is based on that rating. If the cable is marked with a conductor insulation temperature rating, ampacity adjustment or correction of the conductor can be made based on the conductor temperature marked on the cable.

Where the cable is installed in thermal insulation the adjusted and/or corrected operating ampacity of the conductors cannot exceed those contained in the 60°C column of Table 310.15(B)(16). If Type SE cable is not installed in thermal insulation, the limiting factor on conductor ampacity is the requirement for coordinating the operating ampacity of the conductor with the terminal temperature ratings of electrical equipment contained in 110.14(C).

(b) *Exterior Installations.* In addition to the provisions of this article, service-entrance cable used for feeders or branch circuits, where installed as exterior wiring, shall be installed in accordance with Part I of Article 225. The cable shall be supported in accordance with 334.30. Type USE cable installed as underground feeder and branch circuit cable shall comply with Part II of Article 340.

### 338.12 Uses Not Permitted

(A) **Service-Entrance Cable.** Service-entrance cable (SE) shall not be used under the following conditions or in the following locations:

- (1) Where subject to physical damage unless protected in accordance with 230.50(B)

- (2) Underground with or without a raceway
- (3) For exterior branch circuits and feeder wiring unless the installation complies with the provisions of Part I of Article 225 and is supported in accordance with 334.30 or is used as messenger-supported wiring as permitted in Part II of Article 396

(B) **Underground Service-Entrance Cable.** Underground service-entrance cable (USE) shall not be used under the following conditions or in the following locations:

- (1) For interior wiring
- (2) For aboveground installations except where USE cable emerges from the ground and is terminated in an enclosure at an outdoor location and the cable is protected in accordance with 300.5(D)
- (3) As aerial cable unless it is a multiconductor cable identified for use aboveground and installed as messenger-supported wiring in accordance with 225.10 and Part II of Article 396

Cables marked only as “Type USE service-entrance cable” are not required to have a flame-retardant covering, according to 338.2.

### 338.24 Bending Radius

Bends in Types USE and SE cable shall be so made that the cable will not be damaged. The radius of the curve of the inner edge of any bend, during or after installation, shall not be less than five times the diameter of the cable.

## III. Construction

### 338.100 Construction

Cabled, single-conductor, Type USE constructions recognized for underground use shall be permitted to have a bare copper conductor cabled with the assembly. Type USE single, parallel, or cabled conductor assemblies recognized for underground use shall be permitted to have a bare copper concentric conductor applied. These constructions shall not require an outer overall covering.

Informational Note: See 230.41, Exception, item (2), for directly buried, uninsulated service-entrance conductors.

Type SE or USE cable containing two or more conductors shall be permitted to have one conductor uninsulated.

### 338.120 Marking

Service-entrance cable shall be marked as required in 310.120. Cable with the neutral conductor smaller than the ungrounded conductors shall be so marked.

  - 340.104 Conductors
  - 340.108 Equipment Grounding Conductor
  - 340.112 Insulation
  - 340.116 Sheath

#### I. General

##### 340.1 Scope

This article covers the use, installation, and construction specifications for underground feeder and branch-circuit cable, Type UF.

##### 340.2 Definition

**Underground Feeder and Branch-Circuit Cable, Type UF.** A factory assembly of one or more insulated conductors with an integral or an overall covering of nonmetallic material suitable for direct burial in the earth.

##### 340.6 Listing Requirements

Type UF cable shall be listed.

#### II. Installation

##### 340.10 Uses Permitted

Type UF cable shall be permitted as follows:

- (1) For use underground, including direct burial in the earth. For underground requirements, see 300.5.
- (2) As single-conductor cables. Where installed as single-conductor cables, all conductors of the feeder grounded conductor or branch circuit, including the grounded conductor and equipment grounding conductor, if any, shall be installed in accordance with 300.3.
- (3) For wiring in wet, dry, or corrosive locations under the recognized wiring methods of this *Code*.

- (4) Installed as nonmetallic-sheathed cable. Where so installed, the installation and conductor requirements shall comply with Parts II and III of Article 334 and shall be of the multiconductor type.

Where Type UF cable is installed as nonmetallic-sheathed cable, the ampacity is determined according to 334.80. Where used as interior wiring, the installation requirements of Parts II and III of Article 334 must be complied with.

- (5) For solar photovoltaic systems in accordance with 690.31.
- (6) As single-conductor cables as the nonheating leads for heating cables as provided in 424.43.
- (7) Supported by cable trays. Type UF cable supported by cable trays shall be of the multiconductor type.

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

##### 340.12 Uses Not Permitted

Type UF cable shall not be used as follows:

- (1) As service-entrance cable
- (2) In commercial garages
- (3) In theaters and similar locations
- (4) In motion picture studios
- (5) In storage battery rooms
- (6) In hoistways or on elevators or escalators
- (7) In **hazardous** (classified) locations, except as specifically permitted by other articles in this *Code*
- (8) Embedded in poured cement, concrete, or aggregate, except where embedded in plaster as nonheating leads where permitted in 424.43
- (9) Where exposed to direct rays of the sun, unless identified as sunlight resistant
- (10) Where subject to physical damage
- (11) As overhead cable, except where installed as messenger-supported wiring in accordance with Part II of Article 396

Type UF cable suitable for exposure to the direct rays of the sun is indicated by tag marking and marking on the cable surface with the designation "Sunlight Resistant." This physical protection requirement ensures that Type UF cable, as it emerges from underground, is protected from physical damage.

##### 340.24 Bending Radius

Bends in Type UF cable shall be so made that the cable is not damaged. The radius of the curve of the inner edge of any bend shall not be less than five times the diameter of the cable.

**340.80 Ampacity**

The ampacity of Type UF cable shall be that of 60°C (140°F) conductors in accordance with 310.15.

Where UF cable is installed as nonmetallic-sheathed cable, the ampacity of Type UF cable is determined according to rules for nonmetallic-sheathed cable in 334.80. See 340.10(4).

**III. Construction Specifications****340.104 Conductors**

The conductors shall be sizes 14 AWG copper or 12 AWG aluminum or copper-clad aluminum through 4/0 AWG.

**340.108 Equipment Grounding Conductor**

In addition to the insulated conductors, the cable shall be permitted to have an insulated or bare equipment grounding conductor.

**340.112 Insulation**

The conductors of Type UF shall be one of the moisture-resistant types listed in Table 310.104(A) that is suitable for branch-circuit wiring or one that is identified for such use. Where installed as a substitute wiring method for NM cable, the conductor insulation shall be rated 90°C (194°F).

**340.116 Sheath**

The overall covering shall be flame retardant; moisture, fungus, and corrosion resistant; and suitable for direct burial in the earth.

**I. General****342.1 Scope**

This article covers the use, installation, and construction specifications for intermediate metal conduit (IMC) and associated fittings.

Intermediate metal conduit (IMC) is thinner-walled and lighter in weight than rigid metal conduit, and is satisfactory for uses in all locations where rigid metal conduit (RMC) is permitted to be used. Threaded fittings, couplings, connectors, and so on, are interchangeable between IMC and RMC. Threadless fittings for IMC are suitable only for the type of conduit indicated by the marking on the carton.

**342.2 Definition**

**Intermediate Metal Conduit (IMC).** A steel threadable raceway of circular cross section designed for the physical protection and routing of conductors and cables and for use as an equipment grounding conductor when installed with its integral or associated coupling and appropriate fittings.

**342.6 Listing Requirements**

IMC, factory elbows and couplings, and associated fittings shall be listed.

## II. Installation

### 342.10 Uses Permitted

**(A) All Atmospheric Conditions and Occupancies.** Use of IMC shall be permitted under all atmospheric conditions and occupancies.

**(B) Corrosion Environments.** IMC, elbows, couplings, and fittings shall be permitted to be installed in concrete, in direct contact with the earth, or in areas subject to severe corrosive influences where protected by corrosion protection and judged suitable for the condition.

**(C) Cinder Fill.** IMC shall be permitted to be installed in or under cinder fill where subject to permanent moisture where protected on all sides by a layer of noncinder concrete not less than 50 mm (2 in.) thick; where the conduit is not less than 450 mm (18 in.) under the fill; or where protected by corrosion protection and judged suitable for the condition.

**(D) Wet Locations.** All supports, bolts, straps, screws, and so forth, shall be of corrosion-resistant materials or protected against corrosion by corrosion-resistant materials.

Informational Note: See 300.6 for protection against corrosion.

Section 342.10 emphasizes the need for corrosion protection for IMC installed in concrete, in direct contact with the earth, or in other areas subject to corrosive influences. However, galvanized IMC installed in concrete does not require supplementary corrosion protection. Similarly, galvanized IMC installed in contact with soil does not generally require supplementary corrosion protection. As a guide in the absence of experience with the corrosive effects of soil in a specific location, soils producing severe corrosive effects are generally characterized by low resistivity of less than 2000 ohm-cm.

Wherever ferrous metal conduit runs directly from concrete encasement to soil burial, the metal in contact with the soil can be severely corroded.

### 342.14 Dissimilar Metals

Where practicable, dissimilar metals in contact anywhere in the system shall be avoided to eliminate the possibility of galvanic action.

Aluminum fittings and enclosures shall be permitted to be used with IMC.

### 342.20 Size

**(A) Minimum.** IMC smaller than metric designator 16 (trade size ½) shall not be used.

**(B) Maximum.** IMC larger than metric designator 103 (trade size 4) shall not be used.

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

Table 300.1(C) identifies a distinct metric designator for each circular raceway trade size. For further explanation of metric designators, see 90.9 and the commentary following Table 300.1(C).

### 342.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

Table 1 of Chapter 9 specifies the maximum fill percentage of a conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each conductor. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the look-up tables in Informative Annex C can be used instead of performing calculations. Informative Annex C, which contains 12 sets of tables, accurately indicates the maximum number of conductors permitted in a conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

Table 4 of Chapter 9, in the section entitled “Article 342 — Intermediate Metal Conduit (IMC),” lists the metric designators, trade sizes, and other specifications for IMC. Use of Tables C.4 and C.4(A) for intermediate metal conduit in Informative Annex C is also permissible.

### 342.24 Bends — How Made

Bends of IMC shall be so made that the conduit will not be damaged and the internal diameter of the conduit will not be effectively reduced. The radius of the curve of any field bend to the centerline of the conduit shall not be less than indicated in Table 2, Chapter 9.

Table 2 of Chapter 9 is the common table for raceway field bend measurements. *Field bend* refers to any bend or offset

made by installers, using proper tools and equipment, during the installation of conduit systems.

### 342.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

Section 342.26 limits the number of bends in one run to reduce pulling tension on conductors and helps ensure easy insertion or removal of conductors during later phases of construction, when the conduit may be permanently enclosed by the finish of the building.

### 342.28 Reaming and Threading

All cut ends shall be reamed or otherwise finished to remove rough edges. Where conduit is threaded in the field, a standard cutting die with a taper of 1 in 16 ( $\frac{3}{4}$  in. taper per foot) shall be used.

Informational Note: See ANSI/ASME B.1.20.1-1983, *Standard for Pipe Threads, General Purpose (Inch)*.

Conduit is cut using a saw or a roll cutter (pipe cutter). Care should be taken to ensure a straight cut, given that crooked threads result from a die not started on the pipe squarely. After the cut is made, the conduit must be reamed. Proper reaming removes burrs from the interior of the cut conduit so that as wires and cables are pulled through the conduit, no chafing of the insulation or cable jacket occurs. Finally, the conduit is threaded. The number of threads is important, because cutting too many threads prevents a conduit from being made up properly. If a threaded ring gauge is not available, the same number of threads on the conduit are cut as are present on the factory (threaded) end of the conduit.

### 342.30 Securing and Supporting

IMC shall be installed as a complete system in accordance with 300.18 and shall be securely fastened in place and supported in accordance with 342.30(A) and (B).

**(A) Securely Fastened.** IMC shall be secured in accordance with one of the following:

- (1) IMC shall be securely fastened within 900 mm (3 ft) of each outlet box, junction box, device box, cabinet, conduit body, or other conduit termination.
- (2) Where structural members do not readily permit fastening within 900 mm (3 ft), fastening shall be permitted to be increased to a distance of 1.5 m (5 ft).
- (3) Where approved, conduit shall not be required to be securely fastened within 900 mm (3 ft) of the service head for above-the-roof termination of a mast.

Intermediate metal conduit (IMC) is required by 342.30(A) to be securely fastened at least every 10 ft, as illustrated in Exhibit 342.1. Fastening is also required within 3 ft of outlet boxes, junction boxes, cabinets, and conduit bodies. However, where structural support members do not permit fastening within 3 ft, the support may be located up to 5 ft away. This section was reformatted for the 2011 *Code*. However, there are no technical changes to the requirements.

**(B) Supports.** IMC shall be supported in accordance with one of the following:

- (1) Conduit shall be supported at intervals not exceeding 3 m (10 ft).
- (2) The distance between supports for straight runs of conduit shall be permitted in accordance with Table 344.30(B)(2), provided the conduit is made up with threaded couplings and such supports prevent transmission of stresses to termination where conduit is deflected between supports.
- (3) Exposed vertical risers from industrial machinery or fixed equipment shall be permitted to be supported at intervals not exceeding 6 m (20 ft) if the conduit is made up with threaded couplings, the conduit is supported and securely fastened at the top and bottom of the riser, and no other means of intermediate support is readily available.
- (4) Horizontal runs of IMC supported by openings through framing members at intervals not exceeding 3 m (10 ft)

**EXHIBIT 342.1** Minimum fastening requirements for intermediate metal conduit according to 342.30(A).

and securely fastened within 900 mm (3 ft) of termination points shall be permitted.

Section 342.30(B)(4) permits lengths of IMC to be supported (but not necessarily secured) by framing members at 10-ft intervals, provided the IMC is secured and supported at least 3 ft from the box or enclosure. Exhibit 342.2 illustrates an installation where the IMC is installed through the bar joists.

**EXHIBIT 342.2** An example of intermediate metal conduit supported by framing members and securely fastened at the 3-ft distance from the box, as required by 342.30(B)(4).

### 342.42 Couplings and Connectors

**(A) Threadless.** Threadless couplings and connectors used with conduit shall be made tight. Where buried in masonry or concrete, they shall be the concretetight type. Where installed in wet locations, they shall comply with 314.15. Threadless couplings and connectors shall not be used on threaded conduit ends unless listed for the purpose.

See the commentary following 344.42(A) for examples of threadless fittings.

**(B) Running Threads.** Running threads shall not be used on conduit for connection at couplings.

### 342.46 Bushings

Where a conduit enters a box, fitting, or other enclosure, a bushing shall be provided to protect the wires from abrasion unless the box, fitting, or enclosure is designed to provide such protection.

Informational Note: See 300.4(G) for the protection of conductors 4 AWG and larger at bushings.

### 342.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 342.60 Grounding

IMC shall be permitted as an equipment grounding conductor.

## III. Construction Specifications

### 342.120 Marking

Each length shall be clearly and durably marked at least every 1.5 m (5 ft) with the letters IMC. Each length shall be marked as required in 110.21.

### 342.130 Standard Lengths

The standard length of IMC shall be 3.05 m (10 ft), including an attached coupling, and each end shall be threaded. Longer or shorter lengths with or without coupling and threaded or unthreaded shall be permitted.

## III. Construction Specifications

344.120 Marking

344.130 Standard Lengths

## I. General

## 344.1 Scope

This article covers the use, installation, and construction specifications for rigid metal conduit (RMC) and associated fittings.

## 344.2 Definition

**Rigid Metal Conduit (RMC).** A threadable raceway of circular cross section designed for the physical protection and routing of conductors and cables and for use as an equipment grounding conductor when installed with its integral or associated coupling and appropriate fittings. RMC is generally made of steel (ferrous) with protective coatings or aluminum (nonferrous). Special use types are red brass and stainless steel.

## 344.6 Listing Requirements

RMC, factory elbows and couplings, and associated fittings shall be listed.

## II. Installation

## 344.10 Uses Permitted

## (A) Atmospheric Conditions and Occupancies.

(1) **Galvanized Steel and Stainless Steel RMC.** Galvanized steel and stainless steel RMC shall be permitted under all atmospheric conditions and occupancies.

(2) **Red Brass RMC.** Red brass RMC shall be permitted to be installed for direct burial and swimming pool applications.

(3) **Aluminum RMC.** Aluminum RMC shall be permitted to be installed where judged suitable for the environment. Rigid aluminum conduit encased in concrete or in direct contact with the earth shall be provided with approved supplementary corrosion protection.

(4) **Ferrous Raceways and Fittings.** Ferrous raceways and fittings protected from corrosion solely by enamel shall be permitted only indoors and in occupancies not subject to severe corrosive influences.

## (B) Corrosive Environments.

Section 344.10 indicates the permitted uses for listed ferrous and nonferrous conduit, including their use in concrete, in

direct contact with the earth, and in corrosive areas. The informational note to 344.10(D) references 300.6 for additional information on protection against corrosion and specific types of corrosion-resistant materials.

The authority having jurisdiction for enforcing the *Code* should be consulted for approval of corrosion-resistant materials or for requirements prior to the installation of nonferrous metal (aluminum) conduit in concrete, since chloride additives in the concrete mix may cause corrosion.

(1) **Galvanized Steel, Stainless Steel, and Red Brass RMC, Elbows, Couplings, and Fittings.** Galvanized steel, stainless steel, and red brass RMC elbows, couplings, and fittings shall be permitted to be installed in concrete, in direct contact with the earth, or in areas subject to severe corrosive influences where protected by corrosion protection and judged suitable for the condition.

(2) **Supplementary Protection of Aluminum RMC.** Aluminum RMC shall be provided with approved supplementary corrosion protection where encased in concrete or in direct contact with the earth.

(C) **Cinder Fill.** Galvanized steel, stainless steel, and red brass RMC shall be permitted to be installed in or under cinder fill where subject to permanent moisture where protected on all sides by a layer of noncinder concrete not less than 50 mm (2 in.) thick; where the conduit is not less than 450 mm (18 in.) under the fill; or where protected by corrosion protection and judged suitable for the condition.

Although cinder fill is not commonly used in modern construction, it is still encountered at older building sites. Where cinders have been used as fill, they may contain sulfur, and where they have combined with moisture, sulfuric acid is formed, which can corrode metal raceways.

(D) **Wet Locations.** All supports, bolts, straps, screws, and so forth, shall be of corrosion-resistant materials or protected against corrosion by corrosion-resistant materials.

Informational Note: See 300.6 for protection against corrosion.

## 344.14 Dissimilar Metals

Where practicable, dissimilar metals in contact anywhere in the system shall be avoided to eliminate the possibility of galvanic action. Aluminum fittings and enclosures shall be permitted to be used with steel RMC, and steel fittings and enclosures shall be permitted to be used with aluminum RMC where not subject to severe corrosive influences.

Section 344.14 makes clear that aluminum rigid conduit can be used with steel fittings and enclosures, as can aluminum fittings and enclosures with steel rigid conduit. Tests have shown that the galvanic corrosion at steel and aluminum interfaces is minor compared to the natural corrosion on the combination of steel and steel or of aluminum and aluminum.

### 344.20 Size

**(A) Minimum.** RMC smaller than metric designator 16 (trade size ½) shall not be used.

*Exception: For enclosing the leads of motors as permitted in 430.245(B).*

**(B) Maximum.** RMC larger than metric designator 155 (trade size 6) shall not be used.

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

Table 300.1(C) identifies a distinct metric designator for each circular raceway trade size. For further explanation of metric designators, see 90.9 and the commentary following Table 300.1(C).

### 344.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

Table 1 of Chapter 9 specifies the maximum fill percentage of a conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each conductor. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, Informative Annex C can be used instead of performing the calculations. Informative Annex C, through 12 sets of tables, accurately indicates the maximum number of conductors permitted in a conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

To select the proper trade size of rigid metal conduit, the section entitled “Article 344 — Rigid Metal Conduit

(RMC)” in Table 4 of Chapter 9 should be followed. Use of Tables C.8 and C.8(A) for rigid metal conduit in Informative Annex C is also permissible.

### 344.24 Bends — How Made

Bends of RMC shall be so made that the conduit will not be damaged and so that the internal diameter of the conduit will not be effectively reduced. The radius of the curve of any field bend to the centerline of the conduit shall not be less than indicated in Table 2, Chapter 9.

The term *field bend* means any bend or offset made by installers, using proper tools and equipment, during the installation of conduit systems. Table 2 of Chapter 9 is the common table for raceway field bend measurements.

### 344.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

Limiting the number of bends in a conduit run reduces pulling tension on conductors and helps ensure easy insertion or removal of conductors during later phases of construction, when the conduit may be permanently enclosed by the finish of the building.

### 344.28 Reaming and Threading

All cut ends shall be reamed or otherwise finished to remove rough edges. Where conduit is threaded in the field, a standard cutting die with a 1 in 16 taper ( $\frac{3}{4}$  in. taper per foot) shall be used.

Informational Note: See ANSI/ASME B.1.20.1-1983, *Standard for Pipe Threads, General Purpose (Inch)*.

Conduit is cut using a saw or a roll cutter (pipe cutter). Care should be taken to ensure a straight cut because crooked threads result from a die not started on the pipe squarely. After the cut is made, the conduit must be reamed. Proper reaming removes burrs from the interior of the cut conduit so that as wires and cables are pulled through the conduit, no chafing of the insulation or cable jacket occurs. Finally, the conduit is threaded. The number of threads is important. To determine the correct number of threads for a conduit end, the same number of threads on the conduit are cut as are present on the factory (threaded) end of the conduit. Where excessive threads are cut on the conduit and threaded couplings are installed, the conduits within the coupling will

butt, resulting in a weak mechanical joint and poor grounding continuity.

### 344.30 Securing and Supporting

RMC shall be installed as a complete system in accordance with 300.18 and shall be securely fastened in place and supported in accordance with 344.30(A) and (B).

**(A) Securely Fastened.** RMC shall be securely fastened within 900 mm (3 ft) of each outlet box, junction box, device box, cabinet, conduit body, or other conduit termination. Fastening shall be permitted to be increased to a distance of 1.5 m (5 ft) where structural members do not readily permit fastening within 900 mm (3 ft). Where approved, conduit shall not be required to be securely fastened within 900 mm (3 ft) of the service head for above-the-roof termination of a mast.

As illustrated in Exhibit 344.1, rigid metal conduit is required to be securely fastened to at least every 10 ft. Secure fastening is also required within 3 ft of outlet boxes, junction boxes, cabinets, and conduit bodies. However, where structural support members do not permit fastening within 3 ft, secure fastening may be located up to 5 ft away.

**(B) Supports.** RMC shall be supported in accordance with one of the following:

- (1) Conduit shall be supported at intervals not exceeding 3 m (10 ft).
- (2) The distance between supports for straight runs of conduit shall be permitted in accordance with Table 344.30(B)(2), provided the conduit is made up with threaded couplings and such supports prevent transmission of stresses to termination where conduit is deflected between supports.
- (3) Exposed vertical risers from industrial machinery or fixed equipment shall be permitted to be supported at intervals not exceeding 6 m (20 ft) if the conduit is made up with threaded couplings, the conduit is supported and securely fastened at the top and bottom of

**TABLE 344.30(B)(2) Supports for Rigid Metal Conduit**

Conduit Size		Maximum Distance Between Rigid Metal Conduit Supports	
Metric Designator	Trade Size	m	ft
16–21	½–¾	3.0	10
27	1	3.7	12
35–41	1¼–1½	4.3	14
53–63	2–2½	4.9	16
78 and larger	3 and larger	6.1	20

the riser, and no other means of intermediate support is readily available.

- (4) Horizontal runs of RMC supported by openings through framing members at intervals not exceeding 3 m (10 ft) and securely fastened within 900 mm (3 ft) of termination points shall be permitted.

Section 344.30(B)(4) permits lengths of rigid metal conduit to be supported (but not necessarily secured) by framing members at 10-ft intervals, provided the rigid metal conduit is secured and supported at least 3 ft from the box or enclosure. Installations where the rigid metal conduit is installed through bar joists are just one example, as illustrated in Exhibit 344.2.

## 344.42 Couplings and Connectors

**(A) Threadless.** Threadless couplings and connectors used with conduit shall be made tight. Where buried in masonry or concrete, they shall be the concretetight type. Where installed in wet locations, they shall comply with 314.15. Threadless couplings and connectors shall not be used on threaded conduit ends unless listed for the purpose.

Exhibit 344.3 illustrates two different conduit fittings: a threadless conduit coupling and a threadless conduit connec-

**EXHIBIT 344.1** Minimum support required for rigid metal conduit according to 344.30(A).

**EXHIBIT 344.2** An example of rigid metal conduit supported by framing members and securely fastened at the 3-ft distance from the box, as required by 344.30(B)(4).

**EXHIBIT 344.3** An example of rigid metal conduit threadless connector (top) and a threadless coupling (bottom) according to 344.42(A). (Courtesy of Cooper Crouse-Hinds)

tor. Threadless fittings may be suitable for other applications such as raintight, concretetight, or even wet locations, provided the product itself or the product carton is marked as such.

In general, threadless fittings are not intended for use over threads, because the fitting will not seat properly. The

threaded end of the conduit should be cut off and reamed before installation.

Exhibit 344.4 illustrates a three-piece threaded coupling (the electrical equivalent of a pipe union), which is used to join two lengths of conduit where it is impossible to turn either length, such as in underground or concrete slab construction. Another fitting for joining conduit is a bolted split coupling.

**EXHIBIT 344.4** A three-piece (union-type) coupling. (Courtesy of Appleton Electric Co., EGS Electrical Group)

**(B) Running Threads.** Running threads shall not be used on conduit for connection at couplings.

### 344.46 Bushings

Where a conduit enters a box, fitting, or other enclosure, a bushing shall be provided to protect the wires from abrasion unless the box, fitting, or enclosure is designed to provide such protection.

Informational Note: See 300.4(G) for the protection of conductors sizes 4 AWG and larger at bushings.

### 344.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 344.60 Grounding

RMC shall be permitted as an equipment grounding conductor.

## III. Construction Specifications

### 344.120 Marking

Each length shall be clearly and durably identified in every 3 m (10 ft) as required in the first sentence of 110.21. Non-ferrous conduit of corrosion-resistant material shall have suitable markings.

**344.130 Standard Lengths**

The standard length of RMC shall be 3.05 m (10 ft), including an attached coupling, and each end shall be threaded. Longer or shorter lengths with or without coupling and threaded or unthreaded shall be permitted.

- 348.60 Grounding and Bonding

**I. General****348.1 Scope**

This article covers the use, installation, and construction specifications for flexible metal conduit (FMC) and associated fittings.

**348.2 Definition**

**Flexible Metal Conduit (FMC).** A raceway of circular cross section made of helically wound, formed, interlocked metal strip.

**348.6 Listing Requirements**

FMC and associated fittings shall be listed.

Listed FMC ½ in. and larger may be installed in unlimited lengths, provided an equipment grounding conductor is installed with the circuit conductors. See 250.118(5) as well as

348.60 for specific requirements related to the use of FMC as an equipment grounding conductor.

**II. Installation****348.10 Uses Permitted**

FMC shall be permitted to be used in exposed and concealed locations.

**348.12 Uses Not Permitted**

FMC shall not be used in the following:

- (1) In wet locations
- (2) In hoistways, other than as permitted in 620.21(A)(1)
- (3) In storage battery rooms
- (4) In any hazardous (classified) location except as permitted by other articles in this *Code*
- (5) Where exposed to materials having a deteriorating effect on the installed conductors, such as oil or gasoline
- (6) Underground or embedded in poured concrete or aggregate
- (7) Where subject to physical damage

**348.20 Size**

**(A) Minimum.** FMC less than metric designator 16 (trade size ½) shall not be used unless permitted in 348.20(A)(1) through (A)(5) for metric designator 12 (trade size ⅜).

- (1) For enclosing the leads of motors as permitted in 430.245(B)
- (2) In lengths not in excess of 1.8 m (6 ft) for any of the following uses:
  - a. For utilization equipment
  - b. As part of a listed assembly
  - c. For tap connections to luminaires as permitted in 410.117(C)

Section 348.20(A)(2) makes it clear that ⅜-in. flexible metal conduit is permitted to be used as the manufactured or field-installed metal raceway (1½ ft to 6 ft in length) to enclose tap conductors between the outlet box and the terminal housing of recessed luminaires. FMC is also permitted to be used as a 6-ft luminaire whip from an outlet box to a luminaire.

Section 604.6(A) permits a smaller minimum size for manufactured wiring systems because the conductors are not as prone to physical damage when assembled under factory-controlled conditions.

- (3) For manufactured wiring systems as permitted in 604.6(A)
- (4) In hoistways as permitted in 620.21(A)(1)

- (5) As part of a listed assembly to connect wired luminaire sections as permitted in 410.137(C)

**(B) Maximum.** FMC larger than metric designator 103 (trade size 4) shall not be used.

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

### 348.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9, or as permitted in Table 348.22, or for metric designator 12 (trade size  $\frac{3}{8}$ ).

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

Table 1 of Chapter 9 specifies the maximum fill percentage of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each of the conductors. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the tables in Informative Annex C may be used instead of performing the calculations. Informative Annex C, with 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

To select the proper trade size of flexible metal conduit, the section entitled “Article 348 — Flexible Metal Conduit

(FMC)” in Table 4 of Chapter 9 should be followed. Use of Tables C.3 and C.3(A) for flexible metal conduit is also permissible.

### 348.24 Bends — How Made

Bends in conduit shall be made so that the conduit is not damaged and the internal diameter of the conduit is not effectively reduced. Bends shall be permitted to be made manually without auxiliary equipment. The radius of the curve to the centerline of any bend shall not be less than shown in Table 2, Chapter 9 using the column “Other Bends.”

Table 2 of Chapter 9 is the common table for raceway field bend measurements.

### 348.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

As with other raceways, a run of flexible metal conduit installed between boxes, conduit bodies, and so on, is not permitted to contain more than the equivalent of four quarter bends (360 degrees total). Proper shaping and support of this flexible wiring method ensures that conductors can be easily installed or withdrawn at any time.

### 348.28 Trimming

All cut ends shall be trimmed or otherwise finished to remove rough edges, except where fittings that thread into the convolutions are used.

**TABLE 348.22 Maximum Number of Insulated Conductors in Metric Designator 12 (Trade Size  $\frac{3}{8}$ ) Flexible Metal Conduit\***

Size (AWG)	Types RFH-2, SF-2		Types TF, XHHW, TW		Types TFN, THHN, THWN		Types FEP, FEBP, PF, PGF	
	Fittings Inside Conduit	Fittings Outside Conduit	Fittings Inside Conduit	Fittings Outside Conduit	Fittings Inside Conduit	Fittings Outside Conduit	Fittings Inside Conduit	Fittings Outside Conduit
18	2	3	3	5	5	8	5	8
16	1	2	3	4	4	6	4	6
14	1	2	2	3	3	4	3	4
12	—	—	1	2	2	3	2	3
10	—	—	1	1	1	1	1	2

\*In addition, one insulated, covered, or bare equipment grounding conductor of the same size shall be permitted.

### 348.30 Securing and Supporting

FMC shall be securely fastened in place and supported in accordance with 348.30(A) and (B).

**(A) Securely Fastened.** FMC shall be securely fastened in place by an approved means within 300 mm (12 in.) of each box, cabinet, conduit body, or other conduit termination and shall be supported and secured at intervals not to exceed 1.4 m (4½ ft).

*Exception No. 1: Where FMC is fished between access points through concealed spaces in finished buildings or structures and supporting is impracticable.*

*Exception No. 2: Where flexibility is necessary after installation, lengths from the last point where the raceway is securely fastened shall not exceed the following:*

- (1) 900 mm (3 ft) for metric designators 16 through 35 (trade sizes ½ through 1¼)
- (2) 1200 mm (4 ft) for metric designators 41 through 53 (trade sizes 1½ through 2)
- (3) 1500 mm (5 ft) for metric designators 63 (trade size 2½) and larger

Exception No. 1 is limited to prevent fished installations of FMC where the installation of supports remains practical. In Exception No. 2, an example of the phrase “where flexibility is necessary after installation” is an installation of flexible metal conduit to a motor mounted on an adjustable or sliding frame, where the frame is required to be movable to perform drive belt maintenance. For the 2011 *Code*, this exception was revised to make it clear that the length that the exception addresses is the length from the last point where the flexible metal conduit is securely fastened.

*Exception No. 3: Lengths not exceeding 1.8 m (6 ft) from a luminaire terminal connection for tap connections to luminaires as permitted in 410.117(C).*

*Exception No. 4: Lengths not exceeding 1.8 m (6 ft) from the last point where the raceway is securely fastened for connections within an accessible ceiling to luminaire(s) or other equipment.*

Exception No. 4 to 348.30(A) correlates this permission of unsupported flexible metal conduit with other wiring methods permitting the same exception throughout Chapter 3. One such example is 320.30(D)(3) for Type AC cable. FMC fittings are not considered to be a means of cable support.

**(B) Supports.** Horizontal runs of FMC supported by openings through framing members at intervals not greater than 1.4 m (4½ ft) and securely fastened within 300 mm (12 in.) of termination points shall be permitted.

### 348.42 Couplings and Connectors

Angle connectors shall not be concealed.

### 348.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 348.60 Grounding and Bonding

If used to connect equipment where flexibility is necessary to minimize the transmission of vibration from equipment or to provide flexibility for equipment that requires movement after installation, an equipment grounding conductor shall be installed.

Where flexibility is not required after installation, FMC shall be permitted to be used as an equipment grounding conductor when installed in accordance with 250.118(5).

Where required or installed, equipment grounding conductors shall be installed in accordance with 250.134(B).

Where required or installed, equipment bonding jumpers shall be installed in accordance with 250.102.

According to 348.60, an additional equipment grounding conductor is always required where FMC is used for flexibility. Examples of such installations include using FMC to minimize the transmission of vibration from equipment such as motors or to provide flexibility for floodlights, spotlights, or other equipment that requires adjustment after installation. This section was revised for the 2011 *Code* to correlate this requirement with 250.118(5)(d).

According to the product standard UL 1, *Standard for Flexible Metal Conduit*, FMC longer than 6 ft has not been judged to be suitable for grounding purposes. The general rules for permitting or not permitting FMC for grounding purposes are found in 250.118(5). According to 250.118(5), where the length of the total ground-fault return path exceeds 6 ft or the circuit overcurrent protection exceeds 20 amperes, a separate equipment grounding conductor must be installed with the circuit conductors. The upper sketch in Exhibit 348.1 shows an acceptable application of flexible metal conduit where the total length of any ground return path is limited to 6 ft. The lower sketch shows an application that is unacceptable because the grounding return path for Luminaire 2 exceeds the permitted maximum of 6 ft to the box.

Where FMC is used in hazardous (classified) locations, a bonding jumper is required. See 501.30(B), 502.30(B), and 503.30(B) for details on types of equipment grounding conductors. Section 250.102(E) permits the routing of

**EXHIBIT 348.1** An example of acceptable and unacceptable applications of flexible metal conduit without separate equipment grounding conductors used as a luminaire whip, in accordance with 250.118(5)(c).

equipment bonding jumpers on the outside of the raceway in lengths that are no longer than 6 ft and bonded at each end.

## I. General

### 350.1 Scope

This article covers the use, installation, and construction specifications for liquidtight flexible metal conduit (LFMC) and associated fittings.

Liquidtight flexible metal conduit (LFMC) is intended for use in wet locations or where exposed to oil or coolants, at a maximum temperature of 140°F. LFMC is not intended for use where exposed to gasoline or similar light petroleum solvents unless so marked on the product. LFMC is required to be a listed product. If properly marked for the application, LFMC is permitted for direct burial in the earth. Note that the requirements of 300.5 are applicable to LFMC if installed underground. LFMC is on the permitted list of wiring methods allowed for services (230.43), provided the length does not exceed 6 ft and an equipment bonding jumper is installed in accordance with 250.102. LFMC may be installed in unlimited lengths, provided it meets the other requirements of Article 350 and a separate equipment grounding conductor is installed with the circuit conductors.

Liquidtight flexible nonmetallic conduit (LFNC) is also used extensively in the machine tool and related industries. See 13.5.5 in NFPA 79-2007, *Electrical Standard for Industrial Machinery*, for the uses permitted on an industrial machine.

### 350.2 Definition

**Liquidtight Flexible Metal Conduit (LFMC).** A raceway of circular cross section having an outer liquidtight, nonmetallic, sunlight-resistant jacket over an inner flexible metal core with associated couplings, connectors, and fittings for the installation of electric conductors.

### 350.6 Listing Requirements

LFMC and associated fittings shall be listed.

## II. Installation

### 350.10 Uses Permitted

LFMC shall be permitted to be used in exposed or concealed locations as follows:

- (1) Where conditions of installation, operation, or maintenance require flexibility or protection from liquids, vapors, or solids
- (2) As permitted by 501.10(B), 502.10, 503.10, and 504.20 and in other hazardous (classified) locations where specifically approved, and by 553.7(B)
- (3) For direct burial where listed and marked for the purpose

### 350.12 Uses Not Permitted

LFMC shall not be used as follows:

- (1) Where subject to physical damage
- (2) Where any combination of ambient and conductor temperature produces an operating temperature in excess of that for which the material is approved

### 350.20 Size

**(A) Minimum.** LFMC smaller than metric designator 16 (trade size  $\frac{1}{2}$ ) shall not be used.

*Exception: LFMC of metric designator 12 (trade size  $\frac{3}{8}$ ) shall be permitted as covered in 348.20(A).*

**(B) Maximum.** The maximum size of LFMC shall be metric designator 103 (trade size 4).

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

### 350.22 Number of Conductors or Cables

**(A) Metric Designators 16 through 103 (Trade Sizes  $\frac{1}{2}$  through 4).** The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

**(B) Metric Designator 12 (Trade Size  $\frac{3}{8}$ ).** The number of conductors shall not exceed that permitted in Table 348.22, "Fittings Outside Conduit" columns.

The fill requirements of 350.22(A) for trade sizes  $\frac{1}{2}$  through 4 liquidtight flexible metal conduit are specified in Table 1

of Chapter 9, which gives the maximum percent fill of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each of the conductors. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the tables in Informative Annex C may be used instead of performing the calculations. Informative Annex C, with 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in that annex.

Table 4 of Chapter 9, in the section entitled "Article 350 — Liquidtight Flexible Metal Conduit (LFMC)," lists the metric designators, trade sizes, and other specifications for LFMC. Use of Tables C.7 and C.7(A) for liquidtight flexible metal conduit is also permissible.

The exception to 350.22(A) permits the use of trade size  $\frac{3}{8}$  LFMC under the limited conditions specified in 348.20(A). Section 350.22(B) refers to Table 348.22 for the number of conductors permitted in trade size  $\frac{3}{8}$  LFMC.

### 350.24 Bends — How Made

Bends in conduit shall be so made that the conduit will not be damaged and the internal diameter of the conduit will not be effectively reduced. Bends shall be permitted to be made manually without auxiliary equipment. The radius of the curve to the centerline of any bend shall not be less than required in Table 2, Chapter 9 using the column "Other Bends."

Table 2 of Chapter 9 referenced in 350.24 is the common table for raceway field bend measurements.

### 350.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

## 350.30 Securing and Supporting

LFMC shall be securely fastened in place and supported in accordance with 350.30(A) and (B).

**(A) Securely Fastened.** LFMC shall be securely fastened in place by an approved means within 300 mm (12 in.) of each box, cabinet, conduit body, or other conduit termination and shall be supported and secured at intervals not to exceed 1.4 m (4½ ft).

*Exception No. 1: Where LFMC is fished between access points through concealed spaces in finished buildings or structures and supporting is impractical.*

*Exception No. 2: Where flexibility is necessary after installation, lengths from the last point where the raceway is securely fastened shall not exceed the following:*

- (1) 900 mm (3 ft) for metric designators 16 through 35 (trade sizes ½ through 1¼)
- (2) 1200 mm (4 ft) for metric designators 41 through 53 (trade sizes 1½ through 2)
- (3) 1500 mm (5 ft) for metric designators 63 (trade size 2½) and larger

*Exception No. 3: Lengths not exceeding 1.8 m (6 ft) from a luminaire terminal connection for tap conductors to luminaires, as permitted in 410.117(C).*

*Exception No. 4: Lengths not exceeding 1.8 m (6 ft) from the last point where the raceway is securely fastened for connections within an accessible ceiling to luminaire(s) or other equipment.*

Exception No. 4 to 350.30(A) correlates the permission of unsupported limited lengths of liquidtight flexible metal conduit with other wiring methods permitting the same exception throughout Chapter 3. One such example is 320.30(D)(3) for Type AC cable. LFMC fittings are not considered to be a means of support.

**(B) Supports.** Horizontal runs of LFMC supported by openings through framing members at intervals not greater than 1.4 m (4½ ft) and securely fastened within 300 mm (12 in.) of termination points shall be permitted.

### 350.42 Couplings and Connectors

Angle connectors shall not be concealed.

### 350.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 350.60 Grounding and Bonding

If used to connect equipment where flexibility is necessary to minimize the transmission of vibration from equipment or to provide flexibility for equipment that requires movement after installation, an equipment grounding conductor shall be installed.

Where flexibility is not required after installation, LFMC shall be permitted to be used as an equipment grounding conductor when installed in accordance with 250.118(6).

Where required or installed, equipment grounding conductors shall be installed in accordance with 250.134(B).

Where required or installed, equipment bonding jumpers shall be installed in accordance with 250.102.

Informational Note: See 501.30(B), 502.30(B), 503.30(B), 505.25(B), and 506.25(B) for types of equipment grounding conductors.

## III. Construction Specifications

### 350.120 Marking

LFMC shall be marked according to 110.21. The trade size and other information required by the listing shall also be marked on the conduit. Conduit suitable for direct burial shall be so marked.

## I. General

### 352.1 Scope

This article covers the use, installation, and construction specifications for rigid polyvinyl chloride conduit (PVC) and associated fittings.

Article 352 includes the following listed Type PVC conduits. Beside each PVC-based conduit is the appropriate UL category reference and product standard.

Article 352	UL Product Category Code	UL Standard
Rigid PVC Conduit, Type A	EAZX	ANSI/UL 651A
Rigid PVC Conduit, Type EB	EAZX	ANSI/UL 651A
Rigid PVC Conduit, Schedule 40	DZYR	ANSI/UL 651
Rigid PVC Conduit, Schedule 80	DZYR	ANSI/UL 651

The UL *Guide Information for Electrical Equipment — The White Book-2010* describes rigid polyvinyl chloride conduit, Type PVC, for use in accordance with Article 352 in the following extract.

#### Rigid Nonmetallic Schedule 40 and Schedule 80 PVC Conduit (DZYR)

[Rigid nonmetallic] Schedule 40 conduit is suitable for underground use by direct burial or encasement in concrete. Schedule 40 conduit is also suitable for above-ground use indoors or outdoors exposed to sunlight and weather where not subject to physical damage.

Schedule 80 conduit has a reduced cross-sectional area available for wiring space and is suitable for use wherever Schedule 40 conduit may be used. The marking “Schedule 80 PVC” identifies conduit suitable for use where exposed to physical damage and for installation on poles in accordance with [352.10(F) and 352.12(C) of the] *NEC*.

Unless marked for higher temperature, rigid nonmetallic conduit is intended for use with wire rated 75°C or less including where it is encased in concrete within buildings and where ambient temperature is 50°C or less. Where encased in concrete in trenches outside of buildings it is suitable for use with wires rated 90°C or less.

Listed PVC conduit is inherently resistant to atmosphere containing common industrial corrosive agents and will also withstand vapors or mist of caustic, pickling acids, plating bath and hydrofluoric and chromic acids.

PVC conduit and elbows [and bends] (including couplings) that have been investigated for direct exposure to other reagents may be identified by the designation “Reagent Resistant” printed on the surface of the product. [Further information on reagent resistance may be found in the UL *Electrical Construction Materials Directory* and in ANSI/UL 651, *Schedule 40 and 80 Rigid PVC Conduit*.]

PVC conduit is designed for connection to couplings, fittings, and boxes by the use of a suitable solvent-type cement. Instructions supplied by the solvent-type cement manufacturer describe the method of assembly and precautions to be followed. [Fittings for use with Rigid Polyvinyl Chloride Conduit: Type PVC are covered under UL category (DWTT) Conduit Fittings.]

For examples of requirements specifying the use of Schedule 80 PVC conduit, see 230.50(B)(1) 300.5(D)(4), 300.50(C), 501.10(B)(6), and 551.80(B).

Informational Note: Refer to Article 353 for High Density Polyethylene Conduit: Type HDPE, and Article 355 for Reinforced Thermosetting Resin Conduit: Type RTRC.

### 352.2 Definition

**Rigid Polyvinyl Chloride Conduit (PVC).** A rigid non-metallic conduit of circular cross section, with integral or associated couplings, connectors, and fittings for the installation of electrical conductors and cables.

### 352.6 Listing Requirements

PVC conduit, factory elbows, and associated fittings shall be listed.

## II. Installation

### 352.10 Uses Permitted

The use of PVC conduit shall be permitted in accordance with 352.10(A) through (H).

Informational Note: Extreme cold may cause some nonmetallic conduits to become brittle and, therefore, more susceptible to damage from physical contact.

**(A) Concealed.** PVC conduit shall be permitted in walls, floors, and ceilings.

**(B) Corrosive Influences.** PVC conduit shall be permitted in locations subject to severe corrosive influences as covered

in 300.6 and where subject to chemicals for which the materials are specifically approved.

**(C) Cinders.** PVC conduit shall be permitted in cinder fill.

**(D) Wet Locations.** PVC conduit shall be permitted in portions of dairies, laundries, canneries, or other wet locations, and in locations where walls are frequently washed, the entire conduit system, including boxes and fittings used therewith, shall be installed and equipped so as to prevent water from entering the conduit. All supports, bolts, straps, screws, and so forth, shall be of corrosion-resistant materials or be protected against corrosion by approved corrosion-resistant materials.

**(E) Dry and Damp Locations.** PVC conduit shall be permitted for use in dry and damp locations not prohibited by 352.12.

**(F) Exposed.** PVC conduit shall be permitted for exposed work. PVC conduit used exposed in areas of physical damage shall be identified for the use.

Informational Note: PVC Conduit, Type Schedule 80, is identified for areas of physical damage.

**(G) Underground Installations.** For underground installations, PVC shall be permitted for direct burial and underground encased in concrete. See 300.5 and 300.50.

Section 352.10(G) permits similar PVC products that are manufactured differently to be used for both direct burial and underground encasement in concrete applications. This permitted use is based on the 352.6 requirement that only listed PVC conduit and fittings be used. Homogenous PVC conduit is constructed using a solid wall of PVC, whereas nonhomogenous PVC conduit is a foamed PVC construction covered by a skin or outer layer of solid PVC.

**(H) Support of Conduit Bodies.** PVC conduit shall be permitted to support nonmetallic conduit bodies not larger than the largest trade size of an entering raceway. These conduit bodies shall not support luminaires or other equipment and shall not contain devices other than splicing devices as permitted by 110.14(B) and 314.16(C)(2).

**(I) Insulation Temperature Limitations.** Conductors or cables rated at a temperature higher than the listed temperature rating of PVC conduit shall be permitted to be installed in PVC conduit, provided the conductors or cables are not operated at a temperature higher than the listed temperature rating of the PVC conduit.

This requirement was relocated from 352.12(E) and rewritten as 352.10(I) for the 2011 *Code*. Moving the conductor operating temperature requirements makes it clear that conductors marked with a rated temperature higher than that of the raceway can be used when the conductors are operated within the raceway temperature rating.

One application of 352.10(I) is the use of 105°C-rated medium voltage cables, Type MV, where the cable ampacity at the 105°C rating is reduced to the cable ampacity at 75°C or 90°C and, thus, matches the listed operating temperature rating of the nonmetallic conduit (75°C or 90°C).

### 352.12 Uses Not Permitted

PVC conduit shall not be used under the conditions specified in 352.12(A) through (E).

**(A) Hazardous (Classified) Locations.** In any hazardous (classified) location, except as permitted by other articles of this *Code*.

**(B) Support of Luminaires.** For the support of luminaires or other equipment not described in 352.10(H).

**(C) Physical Damage.** Where subject to physical damage unless identified for such use.

**(D) Ambient Temperatures.** Where subject to ambient temperatures in excess of 50°C (122°F) unless listed otherwise.

**(E) Theaters and Similar Locations.** In theaters and similar locations, except as provided in 518.4 and 520.5.

In addition to the conditions in 352.12(A) through (E), non-metallic conduits are not permitted to be installed in ducts, plenums, and other air-handling spaces. See 300.22, which limits the use of materials in ducts, plenums, and other air-handling spaces that may contribute smoke and products of combustion during a fire.

### 352.20 Size

**(A) Minimum.** PVC conduit smaller than metric designator 16 (trade size ½) shall not be used.

**(B) Maximum.** PVC conduit larger than metric designator 155 (trade size 6) shall not be used.

Informational Note: The trade sizes and metric designators are for identification purposes only and do not relate to actual dimensions. See 300.1(C).

### 352.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

The fill requirements of 352.22 are specified in Table 1 of Chapter 9, which gives the maximum percent fill of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each of the conductors. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the tables in Informative Annex C may be used instead of performing the calculations. Informative Annex C, which contains 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

In Table 4 of Chapter 9 there are four separate subtables that address each of the types of PVC conduit. Each one lists the metric designators, trade sizes, and other specifications for each type of PVC. Utilizing Informative Annex C Tables C.9 and C.9(A) through C.12 and C.12(A) is also permissible, provided the appropriate table for the given type of PVC conduit is used.

For Schedule 80 Type PVC conduit, the cross-sectional area available for conductors is considerably less than that of other raceways of the same trade size due to the extra-thick wall of a Schedule 80 conduit.

### 352.24 Bends — How Made

Bends shall be so made that the conduit will not be damaged and the internal diameter of the conduit will not be effectively reduced. Field bends shall be made only with bending equipment identified for the purpose. The radius of the curve to the centerline of such bends shall not be less than shown in Table 2, Chapter 9.

The term *field bend* refers to any bend or offset made by installers, using proper tools and equipment, during the installation of conduit systems. The pulling of conductors in underground conduit can damage nonmetallic elbows. Metal elbows are often used to ensure the integrity of the raceway. Metal elbows in runs of PVC conduit that are buried at least 18 inches are not required to be bonded to the grounded sys-

tem conductor or the grounding electrode conductor. See 250.80 and the associated commentary. Table 2 of Chapter 9 is the common table for raceway field bend measurements.

### 352.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

Section 352.26 limits the number of bends in a conduit run to reduce pulling tension on the conductors and to help ensure easy insertion or removal of conductors during later phases of construction, when the conduit may be permanently enclosed by the finish of the building. The *Code* does not limit the pull points to conduit bodies and boxes; these are only examples of pull points.

### 352.28 Trimming

All cut ends shall be trimmed inside and outside to remove rough edges.

### 352.30 Securing and Supporting

PVC conduit shall be installed as a complete system as provided in 300.18 and shall be fastened so that movement from thermal expansion or contraction is permitted. PVC conduit shall be securely fastened and supported in accordance with 352.30(A) and (B).

The requirements of 352.30 are on high ambient temperatures and use horizontal-support tests only. Expansion fittings and supports, installed as prescribed, allow for expansion/contraction cycles without damage. See the commentary on expansion fittings following 352.44 for details.

**(A) Securely Fastened.** PVC conduit shall be securely fastened within 900 mm (3 ft) of each outlet box, junction box, device box, conduit body, or other conduit termination. Conduit listed for securing at other than 900 mm (3 ft) shall be permitted to be installed in accordance with the listing.

**(B) Supports.** PVC conduit shall be supported as required in Table 352.30. Conduit listed for support at spacings other than as shown in Table 352.30 shall be permitted to be installed in accordance with the listing. Horizontal runs of PVC conduit supported by openings through framing members at intervals not exceeding those in Table 352.30 and securely fastened within 900 mm (3 ft) of termination points shall be permitted.

**TABLE 352.30 Support of Rigid Polyvinyl Chloride Conduit (PVC)**

Conduit Size		Maximum Spacing Between Supports	
Metric Designator	Trade Size	mm or m	ft
16–27	½–1	900 mm	3
35–53	1¼–2	1.5 m	5
63–78	2½–3	1.8 m	6
91–129	3½–5	2.1 m	7
155	6	2.5 m	8

### 352.44 Expansion Fittings

Expansion fittings for PVC conduit shall be provided to compensate for thermal expansion and contraction where the length change, in accordance with Table 352.44, is expected to be 6 mm (¼ in.) or greater in a straight run between securely mounted items such as boxes, cabinets, elbows, or other conduit terminations.

Since PVC conduit exhibits a considerably greater change in length per degree change in temperature than do metal

raceway systems, 352.44 requires expansion fittings for specific temperature variations. In some areas, outdoor temperature variations of over 100°F are common. According to Table 352.44, a 100-ft run of PVC rigid nonmetallic conduit will change 4.06 in. of length if the temperature change is 100°F. See the commentary example following 300.7(B).

The allowable range of expansion for many PVC conduit expansion couplings is generally 6 in. Information concerning installation and application of this type of coupling may be obtained from manufacturers' instructions.

Expansion fittings are seldom used underground, where temperatures are relatively constant. If PVC conduit is buried or covered immediately, expansion and contraction are not considered a problem.

### 352.46 Bushings

Where a conduit enters a box, fitting, or other enclosure, a bushing or adapter shall be provided to protect the wire from abrasion unless the box, fitting, or enclosure design provides equivalent protection.

Informational Note: See 300.4(G) for the protection of conductors 4 AWG and larger at bushings.

**TABLE 352.44 Expansion Characteristics of PVC Rigid Nonmetallic Conduit Coefficient of Thermal Expansion =  $6.084 \times 10^{-5}$  mm/mm/°C ( $3.38 \times 10^{-5}$  in./in./°F)**

Temperature Change (°C)	Length Change of PVC Conduit (mm/m)	Temperature Change (°F)	Length Change of PVC Conduit (in./100 ft)	Temperature Change (°F)	Length Change of PVC Conduit (in./100 ft)
5	0.30	5	0.20	105	4.26
10	0.61	10	0.41	110	4.46
15	0.91	15	0.61	115	4.66
20	1.22	20	0.81	120	4.87
25	1.52	25	1.01	125	5.07
30	1.83	30	1.22	130	5.27
35	2.13	35	1.42	135	5.48
40	2.43	40	1.62	140	5.68
45	2.74	45	1.83	145	5.88
50	3.04	50	2.03	150	6.08
55	3.35	55	2.23	155	6.29
60	3.65	60	2.43	160	6.49
65	3.95	65	2.64	165	6.69
70	4.26	70	2.84	170	6.90
75	4.56	75	3.04	175	7.10
80	4.87	80	3.24	180	7.30
85	5.17	85	3.45	185	7.50
90	5.48	90	3.65	190	7.71
95	5.78	95	3.85	195	7.91
100	6.08	100	4.06	200	8.11

**352.48 Joints**

All joints between lengths of conduit, and between conduit and couplings, fittings, and boxes, shall be made by an approved method.

**352.56 Splices and Taps**

Splices and taps shall be made in accordance with 300.15.

**352.60 Grounding**

Where equipment grounding is required, a separate equipment grounding conductor shall be installed in the conduit.

*Exception No. 1: As permitted in 250.134(B), Exception No. 2, for dc circuits and 250.134(B), Exception No. 1, for separately run equipment grounding conductors.*

*Exception No. 2: Where the grounded conductor is used to ground equipment as permitted in 250.142.*

**III. Construction Specifications****352.100 Construction**

PVC conduit shall be made of rigid (nonplasticized) polyvinyl chloride (PVC). PVC conduit and fittings shall be composed of suitable nonmetallic material that is resistant to moisture and chemical atmospheres. For use aboveground, it shall also be flame retardant, resistant to impact and crushing, resistant to distortion from heat under conditions likely to be encountered in service, and resistant to low temperature and sunlight effects. For use underground, the material shall be acceptably resistant to moisture and corrosive agents and shall be of sufficient strength to withstand abuse, such as by impact and crushing, in handling and during installation. Where intended for direct burial, without encasement in concrete, the material shall also be capable of withstanding continued loading that is likely to be encountered after installation.

**352.120 Marking**

Each length of PVC conduit shall be clearly and durably marked at least every 3 m (10 ft) as required in the first sentence of 110.21. The type of material shall also be included in the marking unless it is visually identifiable. For conduit recognized for use aboveground, these markings shall be permanent. For conduit limited to underground use only, these markings shall be sufficiently durable to remain legible until the material is installed. Conduit shall be permitted to be surface marked to indicate special characteristics of the material.

Informational Note: Examples of these markings include but are not limited to “limited smoke” and “sunlight resistant.”

**I. General****353.1 Scope**

This article covers the use, installation, and construction specifications for high density polyethylene (HDPE) conduit and associated fittings.

Article 353 includes all of the following listed types of HDPE raceways. Beside each raceway shown is the appropriate UL category reference and product standard.

Article 353	UL Product Category Code	UL Standard
HDPE Conduit, EPEC A	EAZX	ANSI/UL 651A
HDPE Conduit, EPEC B	EAZX	ANSI/UL 651A
HDPE Conduit, Schedule 40	EAZX	ANSI/UL 651A
HDPE Conduit, Schedule 80	EAZX	ANSI/UL 651A
Continuous Length HDPE Conduit	EAZX	ANSI/UL 651B

Product samples of high density polyethylene conduit, Type HDPE conduit are shown in Exhibit 353.1.

**EXHIBIT 353.1** Listed high density polyethylene conduit: Type HDPE conduit. (Courtesy of Blue Diamond Industries, LLC)

Informational Note: Refer to Article 352 for Rigid Polyvinyl Chloride Conduit: Type PVC and Article 355 for Reinforced Thermosetting Resin Conduit: Type RTRC.

### 353.2 Definition

**High Density Polyethylene (HDPE) Conduit.** A nonmetallic raceway of circular cross section, with associated couplings, connectors, and fittings for the installation of electrical conductors.

### 353.6 Listing Requirements

HDPE conduit and associated fittings shall be listed.

## II. Installation

### 353.10 Uses Permitted

The use of HDPE conduit shall be permitted under the following conditions:

- (1) In discrete lengths or in continuous lengths from a reel
- (2) In locations subject to severe corrosive influences as covered in 300.6 and where subject to chemicals for which the conduit is listed
- (3) In cinder fill
- (4) In direct burial installations in earth or concrete

Informational Note to (4): Refer to 300.5 and 300.50 for underground installations.

- (5) Above ground, except as prohibited in 353.12, where encased in not less than 50 mm (2 in.) of concrete.
- (6) Conductors or cables rated at a temperature higher than the listed temperature rating of HDPE conduit shall be permitted to be installed in HDPE conduit, provided the conductors or cables are not operated at a temperature higher than the listed temperature rating of the HDPE conduit.

This requirement was relocated from 353.12(5) and rewritten as 353.10(6) for the 2011 *Code*. Moving the conductor operating temperature requirements makes it clear that conductors marked with a rated temperature higher than that of the raceway can be used when the conductors are operated within the raceway temperature rating.

### 353.12 Uses Not Permitted

HDPE conduit shall not be used under the following conditions:

- (1) Where exposed
- (2) Within a building
- (3) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (4) Where subject to ambient temperatures in excess of 50°C (122°F) unless listed otherwise

### 353.20 Size

**(A) Minimum.** HDPE conduit smaller than metric designator 16 (trade size ½) shall not be used.

**(B) Maximum.** HDPE conduit larger than metric designator 155 (trade size 6) shall not be used.

Informational Note: The trade sizes and metric designators are for identification purposes only and do not relate to actual dimensions. See 300.1(C).

### 353.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

The fill requirements of 353.22 are specified in Table 1 of Chapter 9, which gives the maximum percent fill of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each of the conductors. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the tables in Informative Annex C may be used instead of performing the calculations. Informative Annex C, which contains 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are

provided in the commentary following the introduction in the annex.

Table 4 of Chapter 9 in the section entitled “Articles 352 and 353 — Rigid PVC Conduit (PVC), Schedule 40, and HDPE Conduit,” lists the metric designators, trade sizes, and other specifications for HDPE conduit. Utilizing Tables C.10 and C.10(A) is also permissible. The other type of listed HDPE conduits, such as Types EPEC A, EPEC B, and Schedule 80, are not provided for in Chapter 9, Table 4, or in Informative Annex C.

For Schedule 80 Type HDPE conduit, the cross-sectional area available for conductors is considerably less than that of other raceways of the same trade size due to the extra-thick wall of a Schedule 80 conduit.

### 353.24 Bends — How Made

Bends shall be so made that the conduit will not be damaged and the internal diameter of the conduit will not be effectively reduced. Bends shall be permitted to be made manually without auxiliary equipment, and the radius of the curve to the centerline of such bends shall not be less than shown in Table 354.24. For conduits of metric designators 129 and 155 (trade sizes 5 and 6) the allowable radii of bends shall be in accordance with specifications provided by the manufacturer.

Section 353.24 permits bends in HDPE conduit to be made manually and requires conformance with the minimum bending radius in Table 354.24, not the common bending radius in Chapter 9, Table 2.

This section was revised for the 2011 *Code*. HDPE is now permitted in the larger trade sizes, but Table 354.24 stops at metric designator 103 (trade size 4). This section now refers to the manufacturer’s specifications for how bends must be made.

### 353.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

### 353.28 Trimming

All cut ends shall be trimmed inside and outside to remove rough edges.

### 353.46 Bushings

Where a conduit enters a box, fitting, or other enclosure, a bushing or adapter shall be provided to protect the wire from abrasion unless the box, fitting, or enclosure design provides equivalent protection.

Informational Note: See 300.4(G) for the protection of conductors 4 AWG and larger at bushings.

### 353.48 Joints

All joints between lengths of conduit, and between conduit and couplings, fittings, and boxes, shall be made by an approved method.

Informational Note: HDPE conduit can be joined using either heat fusion, electrofusion, or mechanical fittings.

### 353.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 353.60 Grounding

Where equipment grounding is required, a separate equipment grounding conductor shall be installed in the conduit.

*Exception No. 1: The equipment grounding conductor shall be permitted to be run separately from the conduit where used for grounding dc circuits as permitted in 250.134, Exception No. 2.*

*Exception No. 2: The equipment grounding conductor shall not be required where the grounded conductor is used to ground equipment as permitted in 250.142.*

## III. Construction Specifications

### 353.100 Construction

HDPE conduit shall be composed of high density polyethylene that is resistant to moisture and chemical atmospheres. The material shall be resistant to moisture and corrosive agents and shall be of sufficient strength to withstand abuse, such as by impact and crushing, in handling and during installation. Where intended for direct burial, without encasement in concrete, the material shall also be capable of withstanding continued loading that is likely to be encountered after installation.

### 353.120 Marking

Each length of HDPE shall be clearly and durably marked at least every 3 m (10 ft) as required in 110.21. The type of material shall also be included in the marking.

#### I. General

##### 354.1 Scope

This article covers the use, installation, and construction specifications for nonmetallic underground conduit with conductors (NUCC).

Nonmetallic underground conduit with conductors (preassembled conductors in conduit) has been used by electric utilities for outdoor lighting for several years. It is supplied in continuous lengths on coils or reels or in cartons. It consists of nonmetallic conduit with the conductors pre-installed by the manufacturer. The product is designed to allow conductors to be removed and reinserted.

##### 354.2 Definition

**Nonmetallic Underground Conduit with Conductors (NUCC).** A factory assembly of conductors or cables in-

side a nonmetallic, smooth wall conduit with a circular cross section.

##### 354.6 Listing Requirements

NUCC and associated fittings shall be listed.

#### II. Installation

##### 354.10 Uses Permitted

The use of NUCC and fittings shall be permitted in the following:

- (1) For direct burial underground installation (For minimum cover requirements, see Table 300.5 and Table 300.50 under Rigid Nonmetallic Conduit.)
- (2) Encased or embedded in concrete
- (3) In cinder fill
- (4) In underground locations subject to severe corrosive influences as covered in 300.6 and where subject to chemicals for which the assembly is specifically approved
- (5) Aboveground, except as prohibited in 354.12, where encased in not less than 50 mm (2 in.) of concrete

##### 354.12 Uses Not Permitted

NUCC shall not be used in the following:

- (1) In exposed locations
- (2) Inside buildings

*Exception: The conductor or the cable portion of the assembly, where suitable, shall be permitted to extend within the building for termination purposes in accordance with 300.3.*

- (3) In any hazardous (classified) location, except as permitted by other articles of this Code

##### 354.20 Size

**(A) Minimum.** NUCC smaller than metric designator 16 (trade size ½) shall not be used.

**(B) Maximum.** NUCC larger than metric designator 103 (trade size 4) shall not be used.

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

##### 354.22 Number of Conductors

The number of conductors or cables shall not exceed that permitted by the percentage fill in Table 1, Chapter 9.

##### 354.24 Bends — How Made

Bends shall be manually made so that the conduit will not be damaged and the internal diameter of the conduit will

not be effectively reduced. The radius of the curve of the centerline of such bends shall not be less than shown in Table 354.24.

**TABLE 354.24 Minimum Bending Radius for Nonmetallic Underground Conduit with Conductors (NUCC)**

Conduit Size		Minimum Bending Radius	
Metric Designator	Trade Size	mm	in.
16	½	250	10
21	¾	300	12
27	1	350	14
35	1¼	450	18
41	1½	500	20
53	2	650	26
63	2½	900	36
78	3	1200	48
103	4	1500	60

The bending radius for NUCC does not follow Chapter 9, Table 2, but rather must conform to Table 354.24.

### 354.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between termination points.

### 354.28 Trimming

For termination, the conduit shall be trimmed away from the conductors or cables using an approved method that will not damage the conductor or cable insulation or jacket. All conduit ends shall be trimmed inside and out to remove rough edges.

### 354.46 Bushings

Where the NUCC enters a box, fitting, or other enclosure, a bushing or adapter shall be provided to protect the conductor or cable from abrasion unless the design of the box, fitting, or enclosure provides equivalent protection.

Informational Note: See 300.4(G) for the protection of conductors size 4 AWG or larger.

### 354.48 Joints

All joints between conduit, fittings, and boxes shall be made by an approved method.

### 354.50 Conductor Terminations

All terminations between the conductors or cables and equipment shall be made by an approved method for that type of conductor or cable.

### 354.56 Splices and Taps

Splices and taps shall be made in junction boxes or other enclosures.

### 354.60 Grounding

Where equipment grounding is required, an assembly containing a separate equipment grounding conductor shall be used.

## III. Construction Specifications

### 354.100 Construction

**(A) General.** NUCC is an assembly that is provided in continuous lengths shipped in a coil, reel, or carton.

**(B) Nonmetallic Underground Conduit.** The nonmetallic underground conduit shall be listed and composed of a material that is resistant to moisture and corrosive agents. It shall also be capable of being supplied on reels without damage or distortion and shall be of sufficient strength to withstand abuse, such as impact or crushing, in handling and during installation without damage to conduit or conductors.

**(C) Conductors and Cables.** Conductors and cables used in NUCC shall be listed and shall comply with 310.10(C). Conductors of different systems shall be installed in accordance with 300.3(C).

**(D) Conductor Fill.** The maximum number of conductors or cables in NUCC shall not exceed that permitted by the percentage fill in Table 1, Chapter 9.

### 354.120 Marking

NUCC shall be clearly and durably marked at least every 3.05 m (10 ft) as required by 110.21. The type of conduit material shall also be included in the marking.

Identification of conductors or cables used in the assembly shall be provided on a tag attached to each end of the assembly or to the side of a reel. Enclosed conductors or cables shall be marked in accordance with 310.120.

## I. General

### 355.1 Scope

This article covers the use, installation, and construction specification for reinforced thermosetting resin conduit (RTRC) and associated fittings.

**Informational Note:** Refer to Article 352 for Rigid Polyvinyl Chloride Conduit: Type PVC, and Article 353 for High Density Polyethylene Conduit: Type HDPE.

### 355.2 Definition

**Reinforced Thermosetting Resin Conduit (RTRC).** A rigid nonmetallic conduit of circular cross section, with integral or associated couplings, connectors, and fittings for the installation of electrical conductors and cables.

### 355.6 Listing Requirements

RTRC, factory elbows, and associated fittings shall be listed.

## II. Installation

### 355.10 Uses Permitted

The use of RTRC shall be permitted in accordance with 355.10(A) through (I).

**(A) Concealed.** RTRC shall be permitted in walls, floors, and ceilings.

**(B) Corrosive Influences.** RTRC shall be permitted in locations subject to severe corrosive influences as covered in 300.6 and where subject to chemicals for which the materials are specifically approved.

**(C) Cinders.** RTRC shall be permitted in cinder fill.

**(D) Wet Locations.** RTRC shall be permitted in portions of dairies, laundries, canneries, or other wet locations, and in locations where walls are frequently washed, the entire conduit system, including boxes and fittings used therewith, shall be installed and equipped so as to prevent water from entering the conduit. All supports, bolts, straps, screws, and so forth, shall be of corrosion-resistant materials or be protected against corrosion by approved corrosion-resistant materials.

**(E) Dry and Damp Locations.** RTRC shall be permitted for use in dry and damp locations not prohibited by 355.12.

**(F) Exposed.** RTRC shall be permitted for exposed work if identified for such use.

**Informational Note:** RTRC, Type XW, is identified for areas of physical damage.

**(G) Underground Installations.** For underground installations, see 300.5 and 300.50.

**(H) Support of Conduit Bodies.** RTRC shall be permitted to support nonmetallic conduit bodies not larger than the largest trade size of an entering raceway. These conduit bodies shall not support luminaires or other equipment and shall not contain devices other than splicing devices as permitted by 110.14(B) and 314.16(C)(2).

**(I) Insulation Temperature Limitations.** Conductors or cables rated at a temperature higher than the listed temperature rating of RTRC conduit shall be permitted to be installed in RTRC conduit, if the conductors or cables are not operated at a temperature higher than the listed temperature rating of the RTRC conduit.

This requirement was relocated from 355.12(E) and rewritten as 355.10(I) for the 2011 *Code*. Moving the conductor operating temperature requirements makes it clear that conductors marked with a rated temperature higher than that of the raceway can be used when the conductors are operated within the raceway temperature rating.

One application of 355.10(I) is the use of 105°C-rated medium voltage cables, Type MV, where the cable ampacity at the 105°C rating is reduced to the cable ampacity at 90°C and, thus, matches the listed operating temperature rating of the nonmetallic conduit (90°C in the case of RTRC).

### 355.12 Uses Not Permitted

RTRC shall not be used under the following conditions.

#### (A) Hazardous (Classified) Locations.

- (1) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (2) In Class I, Division 2 locations, except as permitted in 501.10(B)(3)

**(B) Support of Luminaires.** For the support of luminaires or other equipment not described in 355.10(H).

**(C) Physical Damage.** Where subject to physical damage unless identified for such use.

RTRC installed in a location where the raceway will be subject to physical damage must be marked “XW.” If the location is above ground and exposed to physical damage, the conduit must be marked “AG XW RTRC.” See the informational note following 355.10(F) for guidance on the marking “XW.” For examples of requirements specifying the use of “RTRC-XW” conduit, see 300.50(C), 334.15(B), 501.10(B)(6), and 551.80(B).

**(D) Ambient Temperatures.** Where subject to ambient temperatures in excess of 50°C (122°F) unless listed otherwise.

•

**(E) Theaters and Similar Locations.** In theaters and similar locations, except as provided in 518.4 and 520.5.

In addition to the conditions in 355.12(A) through (E), non-metallic conduits are not permitted to be installed in ducts, plenums, and other air-handling spaces. See 300.22, which limits the use of materials in ducts, plenums, and other air-handling spaces that may contribute smoke and products of combustion during a fire.

### 355.20 Size

**(A) Minimum.** RTRC smaller than metric designator 16 (trade size ½) shall not be used.

**(B) Maximum.** RTRC larger than metric designator 155 (trade size 6) shall not be used.

Informational Note: The trade sizes and metric designators are for identification purposes only and do not relate to actual dimensions. See 300.1(C).

### 355.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9. Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

Table 1 of Chapter 9 specifies the maximum percent fill of conduit or tubing. However, calculating the number of conductors permitted for Type RTRC conduit is difficult because no dimensions are given in the *Code*. Where dimensions are marked on the conduit, conductor fill calculation may be in accordance with those marked dimensions. For the exact dimensions for fill calculations of RTRC conduit, refer to the product standard or to the manufacturer’s product information.

According to the information within the product standard for RTRC, Schedule 40, the internal diameter dimension of each size is slightly greater than that for intermediate metal conduit, Type IMC. Therefore, using Table C.4 for IMC within Informative Annex C could be a possible solution for determining the number of conductors for a specific size of RTRC Schedule 40 conduit. However, the requirement is that under no circumstances is the maximum fill allowance of Table 1 of Chapter 9 to be exceeded.

### 355.24 Bends — How Made

Bends shall be so made that the conduit will not be damaged and the internal diameter of the conduit will not be effectively reduced. Field bends shall be made only with bending equipment identified for the purpose. The radius of the curve to the centerline of such bends shall not be less than shown in Table 2, Chapter 9.

Table 2 of Chapter 9 is the common table for raceway field bend measurements. The term *field bend* refers to any bend or offset made by installers, using proper tools and equipment, during the installation of conduit systems. The installation of conduits and raceways installed underground is covered in 300.5 and much of the associated commentary.

355.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

Section 355.26 limits the number of bends in a conduit run to reduce pulling tension on conductors and to help ensure easy insertion or removal of conductors during later phases of construction, when the conduit may be permanently enclosed by the finish of the building. The *Code* does not limit the pull points to conduit bodies and boxes; these are only examples of pull points.

355.28 Trimming

All cut ends shall be trimmed inside and outside to remove rough edges.

355.30 Securing and Supporting

RTRC shall be installed as a complete system in accordance with 300.18 and shall be securely fastened in place and supported in accordance with 355.30(A) and (B).

**(A) Securely Fastened.** RTRC shall be securely fastened within 900 mm (3 ft) of each outlet box, junction box, device box, conduit body, or other conduit termination. Conduit listed for securing at other than 900 mm (3 ft) shall be permitted to be installed in accordance with the listing.

**(B) Supports.** RTRC shall be supported as required in Table 355.30. Conduit listed for support at spacing other than as shown in Table 355.30 shall be permitted to be installed in accordance with the listing. Horizontal runs of RTRC supported by openings through framing members at intervals not exceeding those in Table 355.30 and securely fastened within 900 mm (3 ft) of termination points shall be permitted.

TABLE 355.30 Support of Reinforced Thermosetting Resin Conduit (RTRC)

Conduit Size		Maximum Spacing Between Supports	
Metric Designator	Trade Size	mm or m	ft
16–27	½–1	900 mm	3
35–53	1¼–2	1.5 m	5
63–78	2½–3	1.8 m	6
91–129	3½–5	2.1 m	7
155	6	2.5 m	8

355.44 Expansion Fittings

Expansion fittings for RTRC shall be provided to compensate for thermal expansion and contraction where the length change, in accordance with Table 355.44, is expected to be 6 mm (¼ in.) or greater in a straight run between securely mounted items such as boxes, cabinets, elbows, or other conduit terminations.

The requirements of 355.44 are based on high ambient temperatures and use horizontal-support tests only. Expansion fittings and supports, installed as prescribed, allow for expansion/contraction cycles without damage.

Since RTRC conduit exhibits a considerably greater change in length per degree change in temperature than do metal raceway systems, 355.44 requires expansion fittings for specific variations in temperature. In some areas, outdoor temperature variations of over 100°F are common. According to Table 355.44, a 100-ft run of RTRC conduit will change 1.80 in. in length if the temperature change is 100°F. See the commentary example following 300.7(B).

The allowable range of expansion for many conduit expansion couplings is generally 6 in. Information concerning installation and application of this type of coupling may be obtained from manufacturers’ instructions.

Expansion fittings are seldom used underground, where temperatures are relatively constant. If RTRC conduit is buried or covered immediately, expansion and contraction are not considered a problem.

355.46 Bushings

Where a conduit enters a box, fitting, or other enclosure, a bushing or adapter shall be provided to protect the wire from abrasion unless the box, fitting, or enclosure design provides equivalent protection.

Informational Note: See 300.4(G) for the protection of conductors 4 AWG and larger at bushings.

355.48 Joints

All joints between lengths of conduit, and between conduit and couplings, fitting, and boxes, shall be made by an approved method.

355.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

355.60 Grounding

Where equipment grounding is required, a separate equipment grounding conductor shall be installed in the conduit.

*Exception No. 1: As permitted in 250.134(B), Exception No. 2, for dc circuits and 250.134(B), Exception No. 1, for separately run equipment grounding conductors.*

**TABLE 355.44 Expansion Characteristics of Reinforced Thermosetting Resin Conduit (RTRC)**  
Coefficient of Thermal Expansion =  $2.7 \times 10^{-5}$  mm/mm/°C ( $1.5 \times 10^{-5}$  in./in./°F)

Temperature Change (°C)	Length Change of RTRC Conduit (mm/m)	Temperature Change (°F)	Length Change of RTRC Conduit (in./100 ft)	Temperature Change (°F)	Length Change of RTRC Conduit (in./100 ft)
5	0.14	5	0.09	105	1.89
10	0.27	10	0.18	110	1.98
15	0.41	15	0.27	115	2.07
20	0.54	20	0.36	120	2.16
25	0.68	25	0.45	125	2.25
30	0.81	30	0.54	130	2.34
35	0.95	35	0.63	135	2.43
40	1.08	40	0.72	140	2.52
45	1.22	45	0.81	145	2.61
50	1.35	50	0.90	150	2.70
55	1.49	55	0.99	155	2.79
60	1.62	60	1.08	160	2.88
65	1.76	65	1.17	165	2.97
70	1.89	70	1.26	170	3.06
75	2.03	75	1.35	175	3.15
80	2.16	80	1.44	180	3.24
85	2.30	85	1.53	185	3.33
90	2.43	90	1.62	190	3.42
95	2.57	95	1.71	195	3.51
100	2.70	100	1.80	200	3.60

*Exception No. 2: Where the grounded conductor is used to ground equipment as permitted in 250.142.*

### III. Construction Specifications

#### 355.100 Construction

RTRC and fittings shall be composed of suitable nonmetallic material that is resistant to moisture and chemical atmospheres. For use aboveground, it shall also be flame retardant, resistant to impact and crushing, resistant to distortion from heat under conditions likely to be encountered in service, and resistant to low temperature and sunlight effects. For use underground, the material shall be acceptably resistant to moisture and corrosive agents and shall be of sufficient strength to withstand abuse, such as by impact and crushing, in handling and during installation. Where intended for direct burial, without encasement in concrete, the material shall also be capable of withstanding continued loading that is likely to be encountered after installation.

#### 355.120 Marking

Each length of RTRC shall be clearly and durably marked at least every 3 m (10 ft) as required in the first sentence of 110.21. The type of material shall also be included in the marking unless it is visually identifiable. For conduit recognized for use aboveground, these markings shall be permanent. For conduit limited to underground use only, these

markings shall be sufficiently durable to remain legible until the material is installed. Conduit shall be permitted to be surface marked to indicate special characteristics of the material.

Informational Note: Examples of these markings include but are not limited to “limited smoke” and “sunlight resistant.”

## I. General

### 356.1 Scope

This article covers the use, installation, and construction specifications for liquidtight flexible nonmetallic conduit (LFNC) and associated fittings.

Prewired Type LFNC-B is a listed assembly where the conductors are required to be installed at the manufacturing facility, where controlled conditions prevent damage to the conductor insulation. Special cutting tools are required to be used when cutting prewired Type LFNC-B to prevent nicking the conductor installation. This prewired assembly is shown in Exhibit 356.1.

**EXHIBIT 356.1** Listed manufactured prewired assembly of liquidtight flexible nonmetallic conduit, Type B. (Courtesy of Thomas & Betts Corp.)

### 356.2 Definition

**Liquidtight Flexible Nonmetallic Conduit (LFNC).** A raceway of circular cross section of various types as follows:

- (1) A smooth seamless inner core and cover bonded together and having one or more reinforcement layers between the core and covers, designated as Type LFNC-A
- (2) A smooth inner surface with integral reinforcement within the conduit wall, designated as Type LFNC-B

- (3) A corrugated internal and external surface without integral reinforcement within the conduit wall, designated as LFNC-C

LFNC is flame resistant and with fittings and is approved for the installation of electrical conductors.

Informational Note: FNMC is an alternative designation for LFNC.

### 356.6 Listing Requirements

LFNC and associated fittings shall be listed.

## II. Installation

### 356.10 Uses Permitted

LFNC shall be permitted to be used in exposed or concealed locations for the following purposes:

Informational Note: Extreme cold may cause some types of nonmetallic conduits to become brittle and therefore more susceptible to damage from physical contact.

- (1) Where flexibility is required for installation, operation, or maintenance.
- (2) Where protection of the contained conductors is required from vapors, liquids, or solids.
- (3) For outdoor locations where listed and marked as suitable for the purpose.
- (4) For direct burial where listed and marked for the purpose.
- (5) Type LFNC-B shall be permitted to be installed in lengths longer than 1.8 m (6 ft) where secured in accordance with 356.30.
- (6) Type LFNC-B as a listed manufactured prewired assembly, metric designator 16 through 27 (trade size ½ through 1) conduit.
- (7) For encasement in concrete where listed for direct burial and installed in compliance with 356.42.

### 356.12 Uses Not Permitted

LFNC shall not be used as follows:

- (1) Where subject to physical damage
- (2) Where any combination of ambient and conductor temperatures is in excess of that for which the LFNC is approved
- (3) In lengths longer than 1.8 m (6 ft), except as permitted by 356.10(5) or where a longer length is approved as essential for a required degree of flexibility
- (4) Where the operating voltage of the contained conductors is in excess of 600 volts, nominal, except as permitted in 600.32(A)
- (5) In any hazardous (classified) location, except as permitted by other articles in this Code

### 356.20 Size

**(A) Minimum.** LFNC smaller than metric designator 16 (trade size ½) shall not be used unless permitted in 356.20(A)(1) or (A)(2) for metric designator 12 (trade size ⅜).

- (1) For enclosing the leads of motors as permitted in 430.245(B)
- (2) In lengths not exceeding 1.8 m (6 ft) as part of a listed assembly for tap connections to luminaires as required in 410.117(C), or for utilization equipment

**(B) Maximum.** LFNC larger than metric designator 103 (trade size 4) shall not be used.

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

### 356.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

The fill requirements of 356.22 are specified in Table 1 of Chapter 9, which gives the maximum fill percentage of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each of the conductors. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the tables in Informative Annex C may be used instead of performing the calculations. Informative Annex C, with 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

Table 4 of Chapter 9 contains two sections entitled “Article 356 — Liquidtight Flexible Nonmetallic Conduit (LFNC-B)” and “Article 356 — Liquidtight Flexible Nonmetallic Conduit (LFNC-A),” which list the metric designators, trade sizes, and other specifications for LFNC. The construction differences between these two raceway types are explained in 356.2. The use of Tables C.5 and C.5(A), or C.6 and C.6(A), for liquidtight flexible nonmetallic conduit (LFNC-B or LFNC-A) is also permissible.

### 356.24 Bends — How Made

Bends in conduit shall be so made that the conduit is not damaged and the internal diameter of the conduit is not ef-

fectively reduced. Bends shall be permitted to be made manually without auxiliary equipment. The radius of the curve to the centerline of any bend shall not be less than shown in Table 2, Chapter 9 using the column “Other Bends.”

Table 2 of Chapter 9 is the common table for raceway field bend measurements.

### 356.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

### 356.28 Trimming

All cut ends of conduit shall be trimmed inside and outside to remove rough edges.

### 356.30 Securing and Supporting

Type LFNC-B shall be securely fastened and supported in accordance with one of the following:

- (1) Where installed in lengths exceeding 1.8 m (6 ft), the conduit shall be securely fastened at intervals not exceeding 900 mm (3 ft) and within 300 mm (12 in.) on each side of every outlet box, junction box, cabinet, or fitting.
- (2) Securing or supporting of the conduit shall not be required where it is fished, installed in lengths not exceeding 900 mm (3 ft) at terminals where flexibility is required, or installed in lengths not exceeding 1.8 m (6 ft) from a luminaire terminal connection for tap conductors to luminaires permitted in 410.117(C).
- (3) Horizontal runs of LFNC supported by openings through framing members at intervals not exceeding 900 mm (3 ft) and securely fastened within 300 mm (12 in.) of termination points shall be permitted.
- (4) Securing or supporting of LFNC-B shall not be required where installed in lengths not exceeding 1.8 m (6 ft) from the last point where the raceway is securely fastened for connections within an accessible ceiling to luminaire(s) or other equipment.

The permission to have unsupported 6-ft lengths of liquidtight flexible nonmetallic conduit correlates with other wiring methods permitting the same exception throughout Chapter 3. One such example is 320.30(D)(3) for Type AC cable.

### 356.42 Couplings and Connectors

Only fittings listed for use with LFNC shall be used. Angle connectors shall not be used for concealed raceway installa-

tions. Straight LFNC fittings are permitted for direct burial or encasement in concrete.

### 356.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 356.60 Grounding and Bonding

Where used to connect equipment where flexibility is required, an equipment grounding conductor shall be installed.

Where required or installed, equipment grounding conductors shall be installed in accordance with 250.134(B).

Where required or installed, equipment bonding jumpers shall be installed in accordance with 250.102.

## III. Construction Specifications

### 356.100 Construction

LFNC-B as a prewired manufactured assembly shall be provided in continuous lengths capable of being shipped in a coil, reel, or carton without damage.

### 356.120 Marking

LFNC shall be marked at least every 600 mm (2 ft) in accordance with 110.21. The marking shall include a type designation in accordance with 356.2 and the trade size. Conduit that is intended for outdoor use or direct burial shall be marked.

The type, size, and quantity of conductors used in prewired manufactured assemblies shall be identified by means of a printed tag or label attached to each end of the manufactured assembly and either the carton, coil, or reel. The enclosed conductors shall be marked in accordance with 310.120.

#### 358.100 Construction

#### 358.120 Marking

## I. General

### 358.1 Scope

This article covers the use, installation, and construction specifications for electrical metallic tubing (EMT) and associated fittings.

### 358.2 Definition

**Electrical Metallic Tubing (EMT).** An unthreaded thin-wall raceway of circular cross section designed for the physical protection and routing of conductors and cables and for use as an equipment grounding conductor when installed utilizing appropriate fittings. EMT is generally made of steel (ferrous) with protective coatings or aluminum (non-ferrous).

### 358.6 Listing Requirements

EMT, factory elbows, and associated fittings shall be listed.

## II. Installation

### 358.10 Uses Permitted

**(A) Exposed and Concealed.** The use of EMT shall be permitted for both exposed and concealed work.

**(B) Corrosion Protection.** Ferrous or nonferrous EMT, elbows, couplings, and fittings shall be permitted to be installed in concrete, in direct contact with the earth, or in areas subject to severe corrosive influences where protected by corrosion protection and **approved as** suitable for the condition.

**(C) Wet Locations.** All supports, bolts, straps, screws, and so forth shall be of corrosion-resistant materials or protected against corrosion by corrosion-resistant materials.

Informational Note: See 300.6 for protection against corrosion.

According to the *UL Guide Information for Electrical Equipment — The White Book-2010*, category FJMX, galvanized steel EMT installed in concrete, on grade or above, generally requires no supplementary corrosion protection. Galvanized steel EMT in concrete slab below grade level may require supplementary corrosion protection. In general, galvanized steel EMT in contact with soil requires supplementary corrosion protection. Where galvanized steel EMT without supplementary corrosion protection extends directly from concrete encasement to soil burial, severe corrosive effects are likely to occur on the metal in contact with the soil.

### 358.12 Uses Not Permitted

EMT shall not be used under the following conditions:

- (1) Where, during installation or afterward, it will be subject to severe physical damage.
- (2) Where protected from corrosion solely by enamel.
- (3) In cinder concrete or cinder fill where subject to permanent moisture unless protected on all sides by a layer of noncinder concrete at least 50 mm (2 in.) thick or unless the tubing is at least 450 mm (18 in.) under the fill.
- (4) In any hazardous (classified) location except as permitted by other articles in this *Code*.
- (5) For the support of luminaires or other equipment except conduit bodies no larger than the largest trade size of the tubing.
- (6) Where practicable, dissimilar metals in contact anywhere in the system shall be avoided to eliminate the possibility of galvanic action.

*Exception: Aluminum fittings and enclosures shall be permitted to be used with steel EMT where not subject to severe corrosive influences.*

### 358.20 Size

**(A) Minimum.** EMT smaller than metric designator 16 (trade size ½) shall not be used.

*Exception: For enclosing the leads of motors as permitted in 430.245(B).*

**(B) Maximum.** The maximum size of EMT shall be metric designator 103 (trade size 4).

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

### 358.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

The fill requirements of 358.22 are specified in Table 1 of Chapter 9, which gives the maximum fill percentage of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each conductor. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, instead of performing the calculations, the tables in Informative Annex C may be used. Informative Annex C, with 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

Table 4 of Chapter 9, in the section entitled “Article 358 — Electrical Metallic Tubing (EMT),” lists the metric designators, trade sizes, and other specifications for EMT. Utilization of Tables C.1 and C.1(A) for electrical metallic tubing is also permissible.

### 358.24 Bends — How Made

Bends shall be made so that the tubing is not damaged and the internal diameter of the tubing is not effectively reduced. The radius of the curve of any field bend to the centerline of the tubing shall not be less than shown in Table 2, Chapter 9 for one-shot and full shoe benders.

Table 2 of Chapter 9 is the common table for raceway field bend measurements.

### 358.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

### 358.28 Reaming and Threading

**(A) Reaming.** All cut ends of EMT shall be reamed or otherwise finished to remove rough edges.

In addition to a reamer, a half-round file has proved practical for removing rough edges. The steel handle of a pair of pump pliers, the nose of side-cutting pliers, or an electrician's knife can be effective on the smaller sizes of EMT as well.

**(B) Threading.** EMT shall not be threaded.

*Exception:* EMT with factory threaded integral couplings complying with 358.100.

### 358.30 Securing and Supporting

EMT shall be installed as a complete system in accordance with 300.18 and shall be securely fastened in place and supported in accordance with 358.30(A) and (B).

**(A) Securely Fastened.** EMT shall be securely fastened in place at least every 3 m (10 ft). In addition, each EMT run between termination points shall be securely fastened within 900 mm (3 ft) of each outlet box, junction box, device box, cabinet, conduit body, or other tubing termination.

Section 358.30(A) requires EMT to be “securely fastened” at the prescribed intervals, as illustrated in Exhibit 358.1.

*Exception No. 1:* Fastening of unbroken lengths shall be permitted to be increased to a distance of 1.5 m (5 ft) where structural members do not readily permit fastening within 900 mm (3 ft).

As illustrated in Exhibit 358.2, Exception No. 1 to 358.30(A) permits boxes secured to ceiling or roof support structural members that are spaced not more than 5 ft apart to serve as support for runs of EMT perpendicular to the axis of the ceiling or roof support members.

*Exception No. 2:* For concealed work in finished buildings or prefinished wall panels where such securing is impracticable, unbroken lengths (without coupling) of EMT shall be permitted to be fished.

**(B) Supports.** Horizontal runs of EMT supported by openings through framing members at intervals not greater than

**EXHIBIT 358.1** Minimum requirements for securely fastening electrical metallic tubing (EMT) unless an exception to 358.30(A) applies.

**EXHIBIT 358.2** An example of an EMT installation complying with 358.30(A), Exception No. 1.

3 m (10 ft) and securely fastened within 900 mm (3 ft) of termination points shall be permitted.

Section 358.30(B) permits horizontal runs of EMT to be supported (but not necessarily secured) by framing members at 10-ft intervals, provided the EMT is secured and supported at least 3 ft from the box or enclosure. See Exhibit 342.2 in the commentary following 342.30(B)(4) for an example.

### 358.42 Couplings and Connectors

Couplings and connectors used with EMT shall be made up tight. Where buried in masonry or concrete, they shall be concretetight type. Where installed in wet locations, they shall comply with 314.15.

Only listed fittings are permitted per 358.6, and 314.15 specifically requires that fittings for use in wet locations be listed for such use. According to UL 797, *Electrical Metallic Tubing — Steel*, listed fittings suitable for use in poured concrete or where exposed to rain are so indicated on the fitting or carton. The term *concretetight* or equivalent on the carton indicates suitability for use in poured concrete. The term *raintight* or the equivalent on the carton indicates suitability for use where directly exposed to rain. See 225.22 and 230.54(A) for raintight requirements as applied to raceways on exterior surfaces of buildings and to service raceways.

Indenter-type fittings are utilized with metallic-coated EMT only and require a special tool supplied by the manufacturer for proper installation. Diametrically opposed indenter-type tools require two sets of indentations nominally 90 degrees apart. Triple-indent tools require one set of indentations.

Fittings have been tested for use only with steel EMT unless specific marking on the device or carton indicates the fittings are suitable for use with aluminum or other material.

### 358.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 358.60 Grounding

EMT shall be permitted as an equipment grounding conductor.

## III. Construction Specifications

### 358.100 Construction

Factory-threaded integral couplings shall be permitted. Where EMT with a threaded integral coupling is used,

threads for both the tubing and coupling shall be factory-made. The coupling and EMT threads shall be designed so as to prevent bending of the tubing at any part of the thread.

### 358.120 Marking

EMT shall be clearly and durably marked at least every 3 m (10 ft) as required in the first sentence of 110.21.

## I. General

### 360.1 Scope

This article covers the use, installation, and construction specifications for flexible metallic tubing (FMT) and associated fittings.

Flexible metallic tubing (FMT) is a type of raceway used for certain specific applications, particularly under the requirements of 300.22(B) and (C) for wiring in ducts, plenums, and other air-handling spaces. FMT is very flexible and is rarely affected by vibration or other movement. It is an effective barrier to gases and products of combustion if installed with matching listed fittings and is of adequate mechanical strength for use where not exposed to physical damage.

Flexible metallic tubing not greater than 6 ft in length is suitable for use as a raceway for branch-circuit tap conductors that supply luminaires where outlet boxes are located not less than 1 ft from the luminaire.

### 360.2 Definition

**Flexible Metallic Tubing (FMT).** A raceway that is circular in cross section, flexible, metallic, and liquidtight without a nonmetallic jacket.

### 360.6 Listing Requirements

FMT and associated fittings shall be listed.

## II. Installation

### 360.10 Uses Permitted

FMT shall be permitted to be used for branch circuits as follows:

- (1) In dry locations
- (2) Where concealed
- (3) In accessible locations
- (4) For system voltages of 1000 volts maximum

The 1000-volt limitation in 360.10(4) prohibits the use of flexible metallic tubing for the secondary circuits of sign ballasts, sign transformers, electronic sign power supplies, or oil burner ignition transformers unless these circuits are less than 1000 volts.

### 360.12 Uses Not Permitted

FMT shall not be used as follows:

- (1) In hoistways
- (2) In storage battery rooms
- (3) In hazardous (classified) locations unless otherwise permitted under other articles in this *Code*
- (4) Underground for direct earth burial, or embedded in poured concrete or aggregate
- (5) Where subject to physical damage
- (6) In lengths over 1.8 m (6 ft)

Unlike flexible metal conduit or liquidtight flexible metal conduit, flexible metallic tubing is limited in use by 360.12(6) to 6-ft lengths.

### 360.20 Size

**(A) Minimum.** FMT smaller than metric designator 16 (trade size  $\frac{1}{2}$ ) shall not be used.

*Exception No. 1: FMT of metric designator 12 (trade size  $\frac{3}{8}$ ) shall be permitted to be installed in accordance with 300.22(B) and (C).*

*Exception No. 2: FMT of metric designator 12 (trade size  $\frac{3}{8}$ ) shall be permitted in lengths not in excess of 1.8 m (6 ft) as part of a listed assembly or for luminaires. See 410.117(C).*

**(B) Maximum.** The maximum size of FMT shall be metric designator 21 (trade size  $\frac{3}{4}$ ).

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

### 360.22 Number of Conductors

**(A) FMT — Metric Designators 16 and 21 (Trade Sizes  $\frac{1}{2}$  and  $\frac{3}{4}$ ).** The number of conductors in metric designators 16 (trade size  $\frac{1}{2}$ ) and 21 (trade size  $\frac{3}{4}$ ) shall not exceed that permitted by the percentage fill specified in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

The fill requirements of 360.22(A) are specified in Table 1 of Chapter 9, which gives the maximum fill percentage of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each of the conductors. Examples using these tables to calculate a conduit or tubing size are provided in the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, the tables in Informative Annex C may be used instead of performing the calculations. Informative Annex C, with 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

Table 4 of Chapter 9, in the section entitled “Article 348 — Flexible Metal Conduit (FMC),” lists the metric designators, trade sizes, and other specifications for FMC. Use of Tables C.3 and C.3(A) for flexible metal conduit for sizes  $\frac{1}{2}$  in. and  $\frac{3}{4}$  in. is also permissible.

**(B) FMT — Metric Designator 12 (Trade Size  $\frac{3}{8}$ ).** The number of conductors in metric designator 12 (trade size  $\frac{3}{8}$ ) shall not exceed that permitted in Table 348.22.

### 360.24 Bends

**(A) Infrequent Flexing Use.** When FMT is infrequently flexed in service after installation, the radii of bends mea-

sured to the inside of the bend shall not be less than specified in Table 360.24(A).

**TABLE 360.24(A) Minimum Radii for Flexing Use**

Metric Designator	Trade Size	Minimum Radii for Flexing Use	
		mm	in.
12	$\frac{3}{8}$	254.0	10
16	$\frac{1}{2}$	317.5	12½
21	$\frac{3}{4}$	444.5	17½

**(B) Fixed Bends.** Where FMT is bent for installation purposes and is not flexed or bent as required by use after installation, the radii of bends measured to the inside of the bend shall not be less than specified in Table 360.24(B).

**TABLE 360.24(B) Minimum Radii for Fixed Bends**

Metric Designator	Trade Size	Minimum Radii for Fixed Bends	
		mm	in.
12	$\frac{3}{8}$	88.9	3½
16	$\frac{1}{2}$	101.6	4
21	$\frac{3}{4}$	127.0	5

•

### 360.56 Splices and Taps

Splices and taps shall be made in accordance with 300.15.

### 360.60 Grounding

FMT shall be permitted as an equipment grounding conductor where installed in accordance with 250.118(7).

## III. Construction Specifications

### 360.120 Marking

FMT shall be marked according to 110.21.

## I. General

### 362.1 Scope

This article covers the use, installation, and construction specifications for electrical nonmetallic tubing (ENT) and associated fittings.

Electrical nonmetallic tubing (ENT) is made of the same material used for PVC conduit (Article 362). The outside diameters of ENT ( $\frac{1}{2}$ -in. through 2-in. trade sizes only) are such that standard couplings and other fittings for rigid PVC conduit can be used.

Because of the corrugations, the raceway can be bent by hand and has some degree of flexibility. ENT is not intended for use where flexibility is necessary, such as at motor terminations to prevent transmission of noise and vibration, or for connection of adjustable luminaires or moving parts. ENT is suitable for the installation of conductors having a temperature rating as indicated on the product. The maximum allowable ambient temperature is 122°F. Exhibit 362.1 shows an example of electrical nonmetallic tubing.

### 362.2 Definition

**Electrical Nonmetallic Tubing (ENT).** A nonmetallic, pliable, corrugated raceway of circular cross section with integral or associated couplings, connectors, and fittings for the installation of electrical conductors. ENT is composed of a material that is resistant to moisture and chemical atmospheres and is flame retardant.

**EXHIBIT 362.1** Various sizes of electrical nonmetallic tubing (ENT) suitable for use in accordance with Article 362. (Courtesy of Thomas & Betts Corp.)

A pliable raceway is a raceway that can be bent by hand with a reasonable force but without other assistance.

### 362.6 Listing Requirements

ENT and associated fittings shall be listed.

## II. Installation

### 362.10 Uses Permitted

For the purpose of this article, the first floor of a building shall be that floor that has 50 percent or more of the exterior wall surface area level with or above finished grade. One additional level that is the first level and not designed for human habitation and used only for vehicle parking, storage, or similar use shall be permitted. The use of ENT and fittings shall be permitted in the following:

- (1) In any building not exceeding three floors above grade as follows:
  - a. For exposed work, where not prohibited by 362.12
  - b. Concealed within walls, floors, and ceilings

Section 362.10(1) permits ENT to be installed either concealed or exposed. Where exposed and subject to physical damage, ENT is required to be protected and is limited to use in buildings not exceeding three floors above grade, per 362.10. Where concealed or above a suspended ceiling (exposed), ENT is permitted to be installed within walls, floors, or ceilings in buildings of three floors or less without the need for fire-rated construction. The three-floor limitation is

based on the likelihood that only a small quantity of ENT would be exposed to fire and that the occupants would have adequate time to exit the building before the products of combustion make the building untenable. Exhibit 362.2 illustrates permitted uses of ENT in a building of three floors or less.

**EXHIBIT 362.2** Examples of permitted uses of ENT in a building not exceeding three floors as prescribed in 362.10(1).

- (2) In any building exceeding three floors above grade, ENT shall be concealed within walls, floors, and ceilings where the walls, floors, and ceilings provide a thermal barrier of material that has at least a 15-minute finish rating as identified in listings of fire-rated assemblies. The 15-minute-finish-rated thermal barrier shall be permitted to be used for combustible or noncombustible walls, floors, and ceilings.

*Exception to (2): Where a fire sprinkler system(s) is installed in accordance with NFPA 13-2010, Standard for the Installation of Sprinkler Systems, on all floors, ENT shall be permitted to be used within walls, floors, and ceilings, exposed or concealed, in buildings exceeding three floors abovegrade.*

**Informational Note:** A finish rating is established for assemblies containing combustible (wood) supports. The finish rating is defined as the time at which the wood stud or wood joist reaches an average temperature rise of 121°C (250°F) or an individual temperature of 163°C (325°F) as measured on the plane of the wood nearest the fire. A finish

rating is not intended to represent a rating for a membrane ceiling.

Section 362.10(2) permits ENT to be installed within the walls, floors, or ceilings of a building of any height where the walls, floors, or ceilings provide a thermal barrier of material that has at least a 15-minute finish rating. It is not permitted or intended that ENT be used exposed in the first three floors of a building that exceeds three floors except as permitted in 362.10(5). Where installed in a building over three floors, ENT must be installed behind the 15-minute thermal barrier on all floors. Exhibit 362.3 illustrates permitted uses of ENT in a building exceeding three floors. In accordance with the exception, fire sprinkler systems can also be used as a construction condition under which an expanded use of ENT is allowed.

**EXHIBIT 362.3** Examples of permitted uses of ENT in a building exceeding three floors as prescribed in 362.10(2).

Interior finish is generally considered to consist of those materials or combinations of materials that form the exposed interior surface of walls and ceilings in a building. Common

interior finish materials include plaster, gypsum wallboard, wood, plywood paneling, fibrous ceiling tiles, and a variety of wall coverings. Ordinary paint, wallpaper, or other similar wall coverings not exceeding  $\frac{1}{8}$  in. in thickness are generally considered incidental to interior finish, except where the authority having jurisdiction deems them a hazard. For more information regarding classification of interior finish material, refer to 10.2.1 of NFPA 101®-2009, *Life Safety Code*®.

The finish rating of a wall or ceiling finish material is the time required for the unexposed surface of the finish membrane to reach an average temperature rise of 250°F above ambient or an individual temperature rise at any one point not exceeding 325°F when the assembly is tested in accordance with NFPA 251, *Standard Methods of Tests of Fire Resistance of Building Construction and Materials* (also known as ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, or ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*).

The finish rating of wall and ceiling finish materials tested and rated by UL as part of wall and ceiling assemblies can be found in the UL *Fire Resistance Directory*, immediately following the assembly rating and just below the design number. Only assemblies containing combustible support members, however, have published finish ratings. Obviously, it is not the intent to limit ENT to constructions consisting of combustible support members. This section is intended to provide a 15-minute thermal barrier as a minimum threshold of acceptability.

Commentary Table 362.1, reproduced from the NFPA *Fire Protection Handbook*, 20th edition (Volume 2, Section 19, Chapter 2, Table 19.2.13), provides ratings for common finish materials. If the finish rating concealing the ENT is unknown or is less than 15 minutes, the ENT can still be used if the installation meets the criteria in 362.10, including the three-floor limitation, where required, and the installation is not prohibited by 362.12. For finish materials not tested and rated in the UL *Fire Resistance Directory*, use Commentary Table 362.1.

- (3) In locations subject to severe corrosive influences as covered in 300.6 and where subject to chemicals for which the materials are specifically approved.
- (4) In concealed, dry, and damp locations not prohibited by 362.12.
- (5) Above suspended ceilings where the suspended ceilings provide a thermal barrier of material that has at least a 15-minute finish rating as identified in listings of fire-rated assemblies, except as permitted in 362.10(1)(a).

*Exception to (5): ENT shall be permitted to be used above suspended ceilings in buildings exceeding three floors above grade where the building is protected throughout by a fire*

**COMMENTARY TABLE 362.1** Various Finishes over Wood Framing, One Side (Combustible) with Exposure on Finish Side

Material	Fire Resistance Rating <sup>a</sup> (min)

<sup>b</sup>Unsanded wood-fiber plaster.

*sprinkler system installed in accordance with NFPA 13-2010, Standard for the Installation of Sprinkler Systems.*

- (6) Encased in poured concrete, or embedded in a concrete slab on grade where ENT is placed on sand or approved screenings, provided fittings identified for this purpose are used for connections.
- (7) For wet locations indoors as permitted in this section or in a concrete slab on or belowgrade, with fittings listed for the purpose.
- (8) Metric designator 16 through 27 (trade size ½ through 1) as listed manufactured prewired assembly.

Informational Note: Extreme cold may cause some types of nonmetallic conduits to become brittle and therefore more susceptible to damage from physical contact.

Prewired ENT is a listed assembly whose conductors must be installed at the manufacturing facility, where controlled conditions prevent damage to the conductor insulation. Special tools are required when cutting prewired ENT to prevent nicking of the conductor insulation. A prewired assembly is shown in Exhibit 362.4.

**EXHIBIT 362.4** Listed manufactured prewired ENT assembly. (Courtesy of Thomas & Betts Corp.)

- (9) Conductors or cables rated at a temperature higher than the listed temperature rating of ENT shall be permitted to be installed in ENT, if the conductors or cables are not operated at a temperature higher than the listed temperature rating of the ENT.

This requirement was relocated from 362.12(4) and rewritten as 362.10(9) for the 2011 *Code*. Moving the conductor operating temperature requirements makes it clear that conductors marked with a rated temperature higher than that of the raceway can be used when the conductors are operated within the raceway temperature rating.

### 362.12 Uses Not Permitted

ENT shall not be used in the following:

- (1) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (2) For the support of luminaires and other equipment
- (3) Where subject to ambient temperatures in excess of 50°C (122°F) unless listed otherwise
- 
- (4) For direct earth burial
- (5) Where the voltage is over 600 volts
- (6) In exposed locations, except as permitted by 362.10(1), 362.10(5), and 362.10(7)
- (7) In theaters and similar locations, except as provided in 518.4 and 520.5
- (8) Where exposed to the direct rays of the sun, unless identified as sunlight resistant
- (9) Where subject to physical damage

### 362.20 Size

**(A) Minimum.** ENT smaller than metric designator 16 (trade size ½) shall not be used.

**(B) Maximum.** ENT larger than metric designator 53 (trade size 2) shall not be used.

Informational Note: See 300.1(C) for the metric designators and trade sizes. These are for identification purposes only and do not relate to actual dimensions.

### 362.22 Number of Conductors

The number of conductors shall not exceed that permitted by the percentage fill in Table 1, Chapter 9.

Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles. The number of cables shall not exceed the allowable percentage fill specified in Table 1, Chapter 9.

The fill requirements of 362.22 are specified in Table 1 of Chapter 9, which gives the maximum fill percentage of conduit or tubing. Table 4 provides the usable area within the selected conduit or tubing, and Table 5 provides the required area for each conductor. Examples using these tables to calculate a conduit or tubing size are provided in

the commentary following Chapter 9, Table 1, Notes to Tables, Note 6.

If the conductors are of the same wire size, Informative Annex C may be consulted. This annex, which contains 12 sets of tables, accurately indicates the maximum number of conductors permitted in conduit or tubing. Examples using Informative Annex C to select a conduit or tubing size are provided in the commentary following the introduction in the annex.

Table 4 of Chapter 9, in the section entitled “Article 362 — Electrical Nonmetallic Tubing (ENT),” lists the metric designators, trade sizes, and other specifications for ENT. Using Tables C.2 and C.2(A) for electrical nonmetallic tubing is also permissible.

### 362.24 Bends — How Made

Bends shall be so made that the tubing will not be damaged and the internal diameter of the tubing will not be effectively reduced. Bends shall be permitted to be made manually without auxiliary equipment, and the radius of the curve to the centerline of such bends shall not be less than shown in Table 2, Chapter 9 using the column “Other Bends.”

### 362.26 Bends — Number in One Run

There shall not be more than the equivalent of four quarter bends (360 degrees total) between pull points, for example, conduit bodies and boxes.

### 362.28 Trimming

All cut ends shall be trimmed inside and outside to remove rough edges.

### 362.30 Securing and Supporting

ENT shall be installed as a complete system in accordance with 300.18 and shall be securely fastened in place and supported in accordance with 362.30(A) and (B).

**(A) Securely Fastened.** ENT shall be securely fastened at intervals not exceeding 900 mm (3 ft). In addition, ENT shall be securely fastened in place within 900 mm (3 ft) of each outlet box, device box, junction box, cabinet, or fitting where it terminates.

*Exception No. 1: Lengths not exceeding a distance of 1.8 m (6 ft) from a luminaire terminal connection for tap connections to lighting luminaires shall be permitted without being secured.*

*Exception No. 2: Lengths not exceeding 1.8 m (6 ft) from the last point where the raceway is securely fastened for connections within an accessible ceiling to luminaire(s) or other equipment.*

As illustrated in Exhibit 362.5, where run on the surface of framing members, ENT is required to be fastened to the framing member every 3 ft and within 3 ft of every box. See 300.4(D) for requirements for protection against physical damage.

**EXHIBIT 362.5** An application of 362.30(A), showing ENT supported every 3 ft and within 3 ft of the outlet box.

As illustrated in Exhibit 362.6, ENT is permitted by Exception No. 1 to be used as luminaire whip without support for lengths not exceeding 6 ft. See 410.67(C) for details on tap conductor wiring.

*Exception No. 3: For concealed work in finished buildings or prefinished wall panels where such securing is impracticable, unbroken lengths (without coupling) of ENT shall be permitted to be fished.*

Exception No. 3 to 362.30(A) permits ENT to be fished into concealed spaces (unsupported) in continuous lengths.

**EXHIBIT 362.6** An application of 362.30(A), Exception No. 1, showing two unsupported lengths of ENT, each permitted to be installed in a length not to exceed 6 ft.

**(B) Supports.** Horizontal runs of ENT supported by openings in framing members at intervals not exceeding 900 mm (3 ft) and securely fastened within 900 mm (3 ft) of termination points shall be permitted.

### 362.46 Bushings

Where a tubing enters a box, fitting, or other enclosure, a bushing or adapter shall be provided to protect the wire from abrasion unless the box, fitting, or enclosure design provides equivalent protection.

Informational Note: See 300.4(G) for the protection of conductors size 4 AWG or larger.

### 362.48 Joints

All joints between lengths of tubing and between tubing and couplings, fittings, and boxes shall be by an approved method.

### 362.56 Splices and Taps

Splices and taps shall be made only in accordance with 300.15.

Informational Note: See Article 314 for rules on the installation and use of boxes and conduit bodies.

### 362.60 Grounding

Where equipment grounding is required, a separate equipment grounding conductor shall be installed in the raceway in compliance with Article 250, Part VI.

## III. Construction Specifications

### 362.100 Construction

ENT shall be made of material that does not exceed the ignitibility, flammability, smoke generation, and toxicity characteristics of rigid (nonplasticized) polyvinyl chloride.

ENT, as a prewired manufactured assembly, shall be provided in continuous lengths capable of being shipped in a coil, reel, or carton without damage.

### 362.120 Marking

ENT shall be clearly and durably marked at least every 3 m (10 ft) as required in the first sentence of 110.21. The type of material shall also be included in the marking. Marking for limited smoke shall be permitted on the tubing that has limited smoke-producing characteristics.

The type, size, and quantity of conductors used in prewired manufactured assemblies shall be identified by means of a printed tag or label attached to each end of the manufactured assembly and either the carton, coil, or reel. The enclosed conductors shall be marked in accordance with 310.120.

### I. General

#### 366.1 Scope

This article covers the use, installation, and construction requirements of metal auxiliary gutters and nonmetallic auxiliary gutters and associated fittings.

#### 366.2 Definitions

**Metallic Auxiliary Gutter.** A sheet metal enclosure used to supplement wiring spaces at meter centers, distribution centers, switchboards, and similar points of wiring systems. The enclosure has hinged or removable covers for housing and protecting electrical wires, cable, and busbars. The enclosure is designed for conductors to be laid or set in place after the enclosures have been installed as a complete system.

**Nonmetallic Auxiliary Gutter.** A flame retardant, nonmetallic enclosure used to supplement wiring spaces at meter centers, distribution centers, switchboards, and similar points of wiring systems. The enclosure has hinged or removable covers for housing and protecting electrical wires, cable, and busbars. The enclosure is designed for conductors to be laid or set in place after the enclosures have been installed as a complete system.

As its name implies, an auxiliary gutter provides additional gutter space for wiring in various types of electrical enclosures and equipment. This additional gutter space may be necessary to provide sufficient room for the number of conductors in an enclosure or to provide adequate wiring bending/deflection space where conductors connect to a terminal. Although the construction of an auxiliary gutter is no different from that of a wireway, it is the field application of this equipment that differentiates an auxiliary gutter from a wireway.

A wireway is a raceway in accordance with the definition of *raceway* in Article 100. Auxiliary gutters supplement enclosure wiring spaces and are not encompassed by the definition of raceway. Therefore, *Code* requirements that

apply only to raceways do not apply to auxiliary gutters. An example of such a requirement is 230.7, which prohibits service conductors from being installed in a raceway with conductors that are not service conductors. This rule applies to wireways installed in accordance with Article 376 and 378. However, an auxiliary gutter installed to supplement the wiring space of a service equipment enclosure is not a wireway and therefore is not subject to 230.7.

### 366.6 Listing Requirements

**(A) Outdoors.** Nonmetallic auxiliary gutters installed outdoors shall comply with the following:

- (1) Be listed as suitable for exposure to sunlight
- (2) Be listed as suitable for use in wet locations
- (3) Be listed for maximum ambient temperature of the installation

**(B) Indoors.** Nonmetallic auxiliary gutters installed indoors shall be listed for the maximum ambient temperature of the installation.

Only nonmetallic auxiliary gutters are required by 366.6 to be listed. Auxiliary gutter sections and associated fittings are identical to those of wireways and, where listed by UL, bear the UL listing mark “Listed Wireway” or “Auxiliary Gutter.” They differ only in their intended use. See 366.2, Definitions, for a clear understanding of auxiliary gutters. See the commentary following 376.1 for a comparative discussion.

## II. Installation

### 366.10 Uses Permitted

**(A) Sheet Metal Auxiliary Gutters.**

**(1) Indoor and Outdoor Use.** Sheet metal auxiliary gutters shall be permitted for indoor and outdoor use.

**(2) Wet Locations.** Sheet metal auxiliary gutters installed in wet locations shall be suitable for such locations.

**(B) Nonmetallic Auxiliary Gutters.** Nonmetallic auxiliary gutters shall be listed for the maximum ambient temperature of the installation and marked for the installed conductor insulation temperature rating.

**(1) Outdoors.** Nonmetallic auxiliary gutters shall be permitted to be installed outdoors where listed and marked as suitable for the purpose.

Informational Note: Extreme cold may cause nonmetallic auxiliary gutters to become brittle and therefore more susceptible to damage from physical contact.

**(2) Indoors.** Nonmetallic auxiliary gutters shall be permitted to be installed indoors.

Section 366.10 provides requirements for both indoor and outdoor installations. Both metal and nonmetallic gutters must have expansion fittings where temperature fluctuations are expected to change gutter length more than ¼ in., according to 366.44. See the informational note following 378.44 regarding expansion characteristics of PVC conduit and PVC nonmetallic wireway. In addition, see the commentary example following 300.7(B).

### 366.12 Uses Not Permitted

Auxiliary gutters shall not be used:

- (1) To enclose switches, overcurrent devices, appliances, or other similar equipment
- (2) To extend a greater distance than 9 m (30 ft) beyond the equipment that it supplements

*Exception: As permitted in 620.35 for elevators, an auxiliary gutter shall be permitted to extend a distance greater than 9 m (30 ft) beyond the equipment it supplements.*

Informational Note: For wireways, see Articles 376 and 378. For busways, see Article 368.

### 366.22 Number of Conductors

**(A) Sheet Metal Auxiliary Gutters.** The sum of the cross-sectional areas of all contained conductors at any cross section of a sheet metal auxiliary gutter shall not exceed 20 percent of the interior cross-sectional area of the sheet metal auxiliary gutter. The adjustment factors in 310.15(B)(3)(a) shall be applied only where the number of current-carrying conductors, including neutral conductors classified as current-carrying under the provisions of 310.15(B)(5), exceeds 30. Conductors for signaling circuits or controller conductors between a motor and its starter and used only for starting duty shall not be considered as current-carrying conductors.

**(B) Nonmetallic Auxiliary Gutters.** The sum of cross-sectional areas of all contained conductors at any cross section of the nonmetallic auxiliary gutter shall not exceed 20 percent of the interior cross-sectional area of the nonmetallic auxiliary gutter.

A common requirement for both metal and nonmetallic auxiliary gutters is that all the contained conductors not exceed 20 percent fill of the interior cross-sectional area of the gutter. The dimensions of insulated conductors, found in Tables 5 and 5A of Chapter 9, can be used to calculate the size of auxiliary gutters.

Where sheet metal auxiliary gutters contain 30 or fewer current-carrying conductors, the correction factors in 310.15(B)(2) do not apply. However, if more than 30 conductors are installed in a sheet metal auxiliary gutter, the ampacity adjustment factors of 310.15(B)(3)(a) apply, and there is no limit on the number of current-carrying conductors up to the 20 percent fill.

The requirements for nonmetallic auxiliary gutters limit the cross-sectional area of all conductors to 20 percent. There is no 30-conductor allowance. The derating factors specified in 310.15(B)(3)(a) must be applied as stated in 366.23(B).

See the example for calculating the size of a wireway in the commentary following 376.22. This calculation method is also applicable to auxiliary gutters.

No limit is placed on the size of conductors that may be installed in an auxiliary gutter; however, see 366.23(A) for ampacity limitations of bare copper or aluminum busbars enclosed in gutters.

### 366.23 Ampacity of Conductors

**(A) Sheet Metal Auxiliary Gutters.** Where the number of current-carrying conductors contained in the sheet metal auxiliary gutter is 30 or less, the adjustment factors specified in 310.15(B)(3)(a) shall not apply. The current carried continuously in bare copper bars in sheet metal auxiliary gutters shall not exceed 1.55 amperes/mm<sup>2</sup> (1000 amperes/in.<sup>2</sup>) of cross section of the conductor. For aluminum bars, the current carried continuously shall not exceed 1.09 amperes/mm<sup>2</sup> (700 amperes/in.<sup>2</sup>) of cross section of the conductor.

**(B) Nonmetallic Auxiliary Gutters.** The adjustment factors specified in 310.15(B)(3)(a) shall be applicable to the current-carrying conductors in the nonmetallic auxiliary gutter.

### 366.30 Securing and Supporting

**(A) Sheet Metal Auxiliary Gutters.** Sheet metal auxiliary gutters shall be supported and secured throughout their entire length at intervals not exceeding 1.5 m (5 ft).

**(B) Nonmetallic Auxiliary Gutters.** Nonmetallic auxiliary gutters shall be supported and secured at intervals not to exceed 900 mm (3 ft) and at each end or joint, unless listed for other support intervals. In no case shall the distance between supports exceed 3 m (10 ft).

### 366.44 Expansion Fittings

Expansion fittings shall be installed where expected length change, due to expansion and contraction due to temperature change, is more than 6 mm (0.25 in.).

### 366.56 Splices and Taps

Splices and taps shall comply with 366.56(A) through (D).

**(A) Within Gutters.** Splices or taps shall be permitted within gutters where they are accessible by means of removable covers or doors. The conductors, including splices and taps, shall not fill the gutter to more than 75 percent of its area.

**(B) Bare Conductors.** Taps from bare conductors shall leave the gutter opposite their terminal connections, and conductors shall not be brought in contact with uninsulated current-carrying parts of different potential.

**(C) Suitably Identified.** All taps shall be suitably identified at the gutter as to the circuit or equipment that they supply.

**(D) Overcurrent Protection.** Tap connections from conductors in auxiliary gutters shall be provided with overcurrent protection as required in 240.21.

To prevent abrasion of the conductor insulation, suitable bushings, shields, and so on, must be provided where conductors pass around bends or between gutters and cabinets and other locations. Sections 366.56(C) and 366.56(D) require all taps from gutters to be identified (as to circuits or equipment) and protected with overcurrent devices per 240.21.

### 366.58 Insulated Conductors

**(A) Deflected Insulated Conductors.** Where insulated conductors are deflected within an auxiliary gutter, either at the ends or where conduits, fittings, or other raceways or cables enter or leave the gutter, or where the direction of the gutter is deflected greater than 30 degrees, dimensions corresponding to one wire per terminal in Table 312.6(A) shall apply.

Section 366.58(A) references Table 312.6(A) for dimensions of deflected insulated conductors. As noted in 366.56(B), insulated conductors are not permitted to come into contact with bare busbars of opposite polarity. This would require conductors to be shaped or formed in a permanent manner to prevent contact with bare busbars within the gutter.

**(B) Auxiliary Gutters Used as Pull Boxes.** Where insulated conductors 4 AWG or larger are pulled through an auxiliary gutter, the distance between raceway and cable entries enclosing the same conductor shall not be less than that required in 314.28(A)(1) for straight pulls and 314.28(A)(2) for angle pulls.

### 366.60 Grounding

Metal auxiliary gutters shall be connected to an equipment grounding conductor(s), to an equipment bonding jumper, or

to the grounded conductor where permitted or required by 250.92(B)(1) or 250.142.

Listed metal auxiliary gutters (and other listed electrically continuous metal raceways) are required to be constructed and installed in a manner that ensures adequate electrical and mechanical continuity of the complete system according to 250.118(13). The references to 250.92(B)(1) or 250.142 in 366.60 point out that the grounding of auxiliary gutters is not just a connection to an equipment grounding conductor (EGC) but also reaches into services as well.

### III. Construction Specifications

#### 366.100 Construction

**(A) Electrical and Mechanical Continuity.** Gutters shall be constructed and installed so that adequate electrical and mechanical continuity of the complete system is secured.

**(B) Substantial Construction.** Gutters shall be of substantial construction and shall provide a complete enclosure for the contained conductors. All surfaces, both interior and exterior, shall be suitably protected from corrosion. Corner joints shall be made tight, and where the assembly is held together by rivets, bolts, or screws, such fasteners shall be spaced not more than 300 mm (12 in.) apart.

**(C) Smooth Rounded Edges.** Suitable bushings, shields, or fittings having smooth, rounded edges shall be provided where conductors pass between gutters, through partitions, around bends, between gutters and cabinets or junction boxes, and at other locations where necessary to prevent abrasion of the insulation of the conductors.

**(D) Covers.** Covers shall be securely fastened to the gutter.

**(E) Clearance of Bare Live Parts.** Bare conductors shall be securely and rigidly supported so that the minimum clearance between bare current-carrying metal parts of different potential mounted on the same surface will not be less than 50 mm (2 in.), nor less than 25 mm (1 in.) for parts that are held free in the air. A clearance not less than 25 mm (1 in.) shall be secured between bare current-carrying metal parts and any metal surface. Adequate provisions shall be made for the expansion and contraction of busbars.

#### 366.120 Marking

**(A) Outdoors.** Nonmetallic auxiliary gutters installed outdoors shall have the following markings:

- (1) Suitable for exposure to sunlight
- (2) Suitable for use in wet locations
- (3) Installed conductor insulation temperature rating

**(B) Indoors.** Nonmetallic auxiliary gutters installed indoors shall be marked with the installed conductor insulation temperature rating.

## I. General Requirements

### 368.1 Scope

This article covers service-entrance, feeder, and branch-circuit busways and associated fittings.

According to the UL *Electrical Construction Equipment Directory* (Green Book), category CWFT, busways and short-run busways are provided with metal enclosures. These enclosures and in some cases an additional ground bus are intended for use as equipment grounding conductors. Some busways are not intended for use ahead of service equipment and are marked with the maximum rating of overcurrent protection to be used on the supply side of the busway.

Busways that have been investigated to determine suitability for installation in a specified position, for use in vertical runs, for support at intervals greater than 5 ft, or for outdoor use are so marked. This marking is on or contiguous to the nameplate incorporating the manufacturer's name and electrical rating. A busway or fitting containing a vapor seal is so marked, but unless marked otherwise, the busway or fitting has not been investigated for passage through a fire-rated wall.

Short-run busways are marked to limit the run to 30 ft or less and no more than 10 ft vertically. They are intended primarily to feed switchboards. Except for transformer stubs, short-run busways are not intended to have intermediate taps. Short-run busways are not ventilated and may be marked for outdoor use.

Busways and associated fittings marked "Short Circuit Current Rating(s) Maximum rms Symmetrical Amps \_\_\_\_\_ Volts \_\_\_\_\_" have been investigated for the rating indicated.

Busways that are intended to supply and support industrial and commercial luminaires are classified as "Lighting Busway" and are so marked. Trolley busway is marked "Trolley Busway" and is additionally marked "Lighting Busway" if intended to supply and support industrial and commercial luminaires. Busway with provisions for insertion of plug-in devices at any point along its length and intended for general use is classified as "Continuous Plug-in Busway" and is so marked. The marking is contiguous to the marking of the manufacturer's name and the electrical rating. Trolley busway should be installed out of the reach of personnel, or it should be otherwise installed to prevent accidental contact with exposed conductors.

Busway marked "Lighting Busway" and protected by overcurrent devices rated in excess of 20 amperes is intended for use only with luminaires employing heavy-duty lampholders unless additional overcurrent protection is provided for the luminaire in accordance with this *Code*.

Exhibit 368.1 illustrates busways, as covered in this article. See also Exhibit 100.1.

**EXHIBIT 368.1** A 10-ft section of feeder busway, which is one type of busway covered by Article 368.

### 368.2 Definition

**Busway.** A grounded metal enclosure containing factory-mounted, bare or insulated conductors, which are usually copper or aluminum bars, rods, or tubes.

Informational Note: For cablebus, refer to Article 370.

## II. Installation

### 368.10 Uses Permitted

Busways shall be permitted to be installed where they are located in accordance with 368.10(A) through (C).

**(A) Exposed.** Busways shall be permitted to be located in the open where visible, except as permitted in 368.10(C).

**(B) Behind Access Panels.** Busways shall be permitted to be installed behind access panels, provided the busways are totally enclosed, of nonventilating-type construction, and installed so that the joints between sections and at fittings are accessible for maintenance purposes. Where installed behind access panels, means of access shall be provided, and either of the following conditions shall be met:

- (1) The space behind the access panels shall not be used for air-handling purposes.
- (2) Where the space behind the access panels is used for environmental air, other than ducts and plenums, there shall be no provisions for plug-in connections, and the conductors shall be insulated.

Unless busways are mounted in the open and are visible, the installation must comply with 368.10(B). Busways are commonly used as feeders and are mounted horizontally in

industrial buildings or mounted vertically in high-rise buildings. See Exhibit 368.2 for an illustration of a busway installed in the space above a dropped or hung ceiling. The space is not being used as an “other space for environmental air” and can contain the plug-in devices for supplying luminaires or other electrical equipment.

**EXHIBIT 368.2** An example of a busway mounted in the space above a hung ceiling.

**(C) Through Walls and Floors.** Busways shall be permitted to be installed through walls or floors in accordance with (C)(1) and (C)(2).

**(1) Walls.** Unbroken lengths of busway shall be permitted to be extended through dry walls.

**(2) Floors.** Floor penetrations shall comply with (a) and (b):

(a) Busways shall be permitted to be extended vertically through dry floors if totally enclosed (unventilated) where passing through and for a minimum distance of 1.8 m (6 ft) above the floor to provide adequate protection from physical damage.

(b) In other than industrial establishments, where a vertical riser penetrates two or more dry floors, a minimum 100-mm (4-in.) high curb shall be installed around all floor openings for riser busways to prevent liquids from entering the opening. The curb shall be installed within 300 mm (12 in.) of the floor opening. Electrical equipment shall be located so that it will not be damaged by liquids that are retained by the curb.

Informational Note: See 300.21 for information concerning the spread of fire or products of combustion.

A busway or fitting containing a vapor seal is so marked, but, unless marked otherwise, the busway or fitting has not been investigated for passage through a fire-rated wall. The requirements of 300.21 are extremely important in order to confine a fire and the products of combustion at their origin.

Section 368.10(C)(2)(b) requires that a curb be placed around a busway if the busway penetrates two or more dry floors. The addition of a 4-in. curb encircling the busway can help eliminate the possibility that a liquid spilled on an upper floor will penetrate and trickle down the vertical rise of the busway, causing damage to the electrical system.

### 368.12 Uses Not Permitted

**(A) Physical Damage.** Busways shall not be installed where subject to severe physical damage or corrosive vapors.

**(B) Hoistways.** Busways shall not be installed in hoistways.

**(C) Hazardous Locations.** Busways shall not be installed in any hazardous (classified) location, unless specifically approved for such use.

Informational Note: See 501.10(B).

**(D) Wet Locations.** Busways shall not be installed outdoors or in wet or damp locations unless identified for such use.

**(E) Working Platform.** Lighting busway and trolley busway shall not be installed less than 2.5 m (8 ft) above the floor or working platform unless provided with a cover identified for the purpose.

### 368.17 Overcurrent Protection

Overcurrent protection shall be provided in accordance with 368.17(A) through (D).

**(A) Rating of Overcurrent Protection — Feeders.** A busway shall be protected against overcurrent in accordance with the allowable current rating of the busway.

*Exception No. 1: The applicable provisions of 240.4 shall be permitted.*

*Exception No. 2: Where used as transformer secondary ties, the provisions of 450.6(A)(3) shall be permitted.*

The rated ampacity of a busway is based on the allowable temperature rise of the conductors and can be determined in the field only by reference to the nameplate data. The appli-

cable sections of 240.4 referenced in Exception No. 1 are 240.4(B) and 240.4(C).

**(B) Reduction in Ampacity Size of Busway.** Overcurrent protection shall be required where busways are reduced in ampacity.

*Exception: For industrial establishments only, omission of overcurrent protection shall be permitted at points where busways are reduced in ampacity, provided that the length of the busway having the smaller ampacity does not exceed 15 m (50 ft) and has an ampacity at least equal to one-third the rating or setting of the overcurrent device next back on the line, and provided that such busway is free from contact with combustible material.*

In industrial establishments, where the size of a smaller busway is kept within the specified limits, the additional cost of providing overcurrent protection at the point where the size is changed is not warranted. For example, a busway protected by a 1200-ampere overcurrent device may be reduced in size, provided the smaller busway has a current rating of 400 amperes ( $\frac{1}{3}$  of 1200 amperes) and does not extend more than 50 ft. In this case, overcurrent protection would be required if the smaller busway were rated less than 400 amperes (e.g., 200 amperes, 300 amperes).

**(C) Feeder or Branch Circuits.** Where a busway is used as a feeder, devices or plug-in connections for tapping off feeder or branch circuits from the busway shall contain the overcurrent devices required for the protection of the feeder or branch circuits. The plug-in device shall consist of an externally operable circuit breaker or an externally operable fusible switch. Where such devices are mounted out of reach and contain disconnecting means, suitable means such as ropes, chains, or sticks shall be provided for operating the disconnecting means from the floor.

Externally operated fused switches and circuit breakers that are plugged into busways and mounted out of reach are to be considered accessible if operated by means such as ropes, chains, or hooksticks.

*Exception No. 1: As permitted in 240.21.*

*Exception No. 2: For fixed or semifixed luminaires, where the branch-circuit overcurrent device is part of the luminaire cord plug on cord-connected luminaires.*

*Exception No. 3: Where luminaires without cords are plugged directly into the busway and the overcurrent device is mounted on the luminaire.*

**(D) Rating of Overcurrent Protection — Branch Circuits.** A busway used as a branch circuit shall be protected against overcurrent in accordance with 210.20.

### 368.30 Support

Busways shall be securely supported at intervals not exceeding 1.5 m (5 ft) unless otherwise designed and marked.

### 368.56 Branches from Busways

Branches from busways shall be permitted to be made in accordance with 368.56(A), (B), and (C).

**(A) General.** Branches from busways shall be permitted to use any of the following wiring methods:

- (1) Type AC armored cable
- (2) Type MC metal-clad cable
- (3) Type MI mineral-insulated, metal-sheathed cable
- (4) Type IMC intermediate metal conduit
- (5) Type RMC rigid metal conduit
- (6) Type FMC flexible metal conduit
- (7) Type LFMC liquidtight flexible metal conduit
- (8) Type PVC rigid polyvinyl chloride conduit
- (9) Type RTRC reinforced thermosetting resin conduit
- (10) Type LFNC liquidtight flexible nonmetallic conduit
- (11) Type EMT electrical metallic tubing
- (12) Type ENT electrical nonmetallic tubing
- (13) Busways
- (14) Strut-type channel raceway
- (15) Surface metal raceway
- (16) Surface nonmetallic raceway

Where a separate equipment grounding conductor is used, connection of the equipment grounding conductor to the busway shall comply with 250.8 and 250.12.

**(B) Cord and Cable Assemblies.** Suitable cord and cable assemblies approved for extra-hard usage or hard usage and listed bus drop cable shall be permitted as branches from busways for the connection of portable equipment or the connection of stationary equipment to facilitate their interchange in accordance with 400.7 and 400.8 and the following conditions:

- (1) The cord or cable shall be attached to the building by an approved means.
- (2) The length of the cord or cable from a busway plug-in device to a suitable tension take-up support device shall not exceed 1.8 m (6 ft).
- (3) The cord and cable shall be installed as a vertical riser from the tension take-up support device to the equipment served.
- (4) Strain relief cable grips shall be provided for the cord or cable at the busway plug-in device and equipment terminations.

*Exception to (B)(2): In industrial establishments only, where the conditions of maintenance and supervision ensure that only qualified persons service the installation, lengths exceeding 1.8 m (6 ft) shall be permitted between the busway plug-in device and the tension take-up support device where the cord or cable is supported at intervals not exceeding 2.5 m (8 ft).*

Exhibit 368.3 illustrates a cable or cord branch from a busway installed according to the requirements of 368.56(B)(2). Section 400.9 specifically prohibits the installation of spliced cords. Exhibit 368.4 illustrates a cable or cord branch from a busway installed according to 368.56(B)(2), Exception.

**EXHIBIT 368.3** An example of a cable or cord branch from a busway installed according to 368.56(B).

**(C) Branches from Trolley-Type Busways.** Suitable cord and cable assemblies approved for extra-hard usage or hard usage and listed bus drop cable shall be permitted as branches from trolley-type busways for the connection of movable equipment in accordance with 400.7 and 400.8.

### 368.58 Dead Ends

A dead end of a busway shall be closed.

**EXHIBIT 368.4** An example of an installation permitted only in industrial occupancies with other restrictions, according to 368.56(B)(2), Exception.

### 368.60 Grounding

Busway shall be connected to an equipment grounding conductor(s), to an equipment bonding jumper, or to the grounded conductor where permitted or required by 250.92(B)(1) or 250.142.

## III. Construction

### 368.120 Marking

Busways shall be marked with the voltage and current rating for which they are designed, and with the manufacturer's name or trademark in such a manner as to be visible after installation.

## IV. Requirements for Over 600 Volts, Nominal

### 368.214 Adjacent and Supporting Structures

Metal-enclosed busways shall be installed so that temperature rise from induced circulating currents in any adjacent metallic parts will not be hazardous to personnel or constitute a fire hazard.

### 368.234 Barriers and Seals

**(A) Vapor Seals.** Busway runs that have sections located both inside and outside of buildings shall have a vapor seal at the building wall to prevent interchange of air between indoor and outdoor sections.

*Exception: Vapor seals shall not be required in forced-cooled bus.*

**(B) Fire Barriers.** Fire barriers shall be provided where fire walls, floors, or ceilings are penetrated.

Informational Note: See 300.21 for information concerning the spread of fire or products of combustion.

### 368.236 Drain Facilities

Drain plugs, filter drains, or similar methods shall be provided to remove condensed moisture from low points in busway run.

### 368.237 Ventilated Bus Enclosures

Ventilated busway enclosures shall be installed in accordance with Article 110, Part III, and 490.24.

### 368.238 Terminations and Connections

Where bus enclosures terminate at machines cooled by flammable gas, seal-off bushings, baffles, or other means shall be provided to prevent accumulation of flammable gas in the busway enclosures.

All conductor termination and connection hardware shall be accessible for installation, connection, and maintenance.

### 368.239 Switches

Switching devices or disconnecting links provided in the busway run shall have the same momentary rating as the busway. Disconnecting links shall be plainly marked to be removable only when bus is de-energized. Switching devices that are not load-break shall be interlocked to prevent operation under load, and disconnecting link enclosures shall be interlocked to prevent access to energized parts.

### 368.240 Wiring 600 Volts or Less, Nominal

Secondary control devices and wiring that are provided as part of the metal-enclosed bus run shall be insulated by fire-retardant barriers from all primary circuit elements with the exception of short lengths of wire, such as at instrument transformer terminals.

### 368.244 Expansion Fittings

Flexible or expansion connections shall be provided in long, straight runs of bus to allow for temperature expansion or contraction, or where the busway run crosses building vibration insulation joints.

### 368.258 Neutral Conductor

Neutral bus, where required, shall be sized to carry all neutral load current, including harmonic currents, and shall have adequate momentary and short-circuit rating consistent with system requirements.

### 368.260 Grounding

Metal-enclosed busway shall be grounded.

### 368.320 Marking

Each busway run shall be provided with a permanent nameplate on which the following information shall be provided:

- (1) Rated voltage.
- (2) Rated continuous current; if bus is forced-cooled, both the normal forced-cooled rating and the self-cooled (not forced-cooled) rating for the same temperature rise shall be given.
- (3) Rated frequency.
- (4) Rated impulse withstand voltage.
- (5) Rated 60-Hz withstand voltage (dry).
- (6) Rated momentary current.
- (7) Manufacturer's name or trademark.

Informational Note: See ANSI C37.23-1987 (R1991), *Guide for Metal-Enclosed Bus and Calculating Losses in Isolated-Phase Bus*, for construction and testing requirements for metal-enclosed buses.

## ARTICLE 370 Cablebus

### Contents

- 370.7 Fittings
- 370.8 Conductor Terminations
- 370.9 Grounding
- 370.10 Marking

### 370.1 Scope

This article covers the use and installation requirements of cablebus and associated fittings.

Cablebus consists of a metal structure or framework installed in a manner similar to that for a cable tray support system. As illustrated in Exhibit 370.1, insulated conductors, 1/0 AWG or

**EXHIBIT 370.1** A section of cablebus with conductors in place and the ventilated top cover ready to be attached to the busway frame. (Courtesy of MP Husky Cable Bus & Cable Tray)

larger, are field installed within the framework on special insulating blocks at specified intervals to provide controlled spacing between conductors. To completely enclose the conductors, a ventilated top cover is attached to the framework.

### 370.2 Definition

**Cablebus.** An assembly of insulated conductors with fittings and conductor terminations in a completely enclosed, ventilated protective metal housing. Cablebus is ordinarily assembled at the point of installation from the components furnished or specified by the manufacturer in accordance with instructions for the specific job. This assembly is designed to carry fault current and to withstand the magnetic forces of such current.

### 370.3 Use

Approved cablebus shall be permitted at any voltage or current for which spaced conductors are rated and shall be installed only for exposed work, except as permitted in 370.6. Cablebus installed outdoors or in corrosive, wet, or damp locations shall be identified for such use. Cablebus shall not be installed in hoistways or hazardous (classified) locations unless specifically approved for such use. Cablebus shall be permitted to be used for branch circuits, feeders, and services.

Cablebus framework, where bonded, shall be permitted to be used as the equipment grounding conductor for branch circuits and feeders.

### 370.4 Conductors

**(A) Types of Conductors.** The current-carrying conductors in cablebus shall have an insulation rating of 75°C

(167°F) or higher and be an approved type suitable for the application.

**(B) Ampacity of Conductors.** The ampacity of conductors in cablebus shall be in accordance with Table 310.15(B)(17) and Table 310.15(B)(19), or with Table 310.60(C)(69) and Table 310.60(C)(70) for installations over 600 volts.

**(C) Size and Number of Conductors.** The size and number of conductors shall be that for which the cablebus is designed, and in no case smaller than 1/0 AWG.

**(D) Conductor Supports.** The insulated conductors shall be supported on blocks or other mounting means designed for the purpose.

The individual conductors in a cablebus shall be supported at intervals not greater than 900 mm (3 ft) for horizontal runs and 450 mm (1½ ft) for vertical runs. Vertical and horizontal spacing between supported conductors shall not be less than one conductor diameter at the points of support.

### 370.5 Overcurrent Protection

Cablebus shall be protected against overcurrent in accordance with the allowable ampacity of the cablebus conductors in accordance with 240.4.

*Exception: Overcurrent protection shall be permitted in accordance with 240.100 and 240.101 for over 600 volts, nominal.*

### 370.6 Support and Extension Through Walls and Floors

**(A) Support.** Cablebus shall be securely supported at intervals not exceeding 3.7 m (12 ft).

*Exception: Where spans longer than 3.7 m (12 ft) are required, the structure shall be specifically designed for the required span length.*

**(B) Transversely Routed.** Cablebus shall be permitted to extend transversely through partitions or walls, other than fire walls, provided the section within the wall is continuous, protected against physical damage, and unventilated.

**(C) Through Dry Floors and Platforms.** Except where firestops are required, cablebus shall be permitted to extend vertically through dry floors and platforms, provided the cablebus is totally enclosed at the point where it passes through the floor or platform and for a distance of 1.8 m (6 ft) above the floor or platform.

**(D) Through Floors and Platforms in Wet Locations.** Except where firestops are required, cablebus shall be permitted to extend vertically through floors and platforms

in wet locations where (1) there are curbs or other suitable means to prevent waterflow through the floor or platform opening, and (2) where the cablebus is totally enclosed at the point where it passes through the floor or platform and for a distance of 1.8 m (6 ft) above the floor or platform.

### 370.7 Fittings

A cablebus system shall include approved fittings for the following:

- (1) Changes in horizontal or vertical direction of the run
- (2) Dead ends
- (3) Terminations in or on connected apparatus or equipment or the enclosures for such equipment
- (4) Additional physical protection where required, such as guards where subject to severe physical damage

### 370.8 Conductor Terminations

Approved terminating means shall be used for connections to cablebus conductors.

### 370.9 Grounding

A cablebus installation shall be grounded and bonded in accordance with Article 250, excluding 250.86, Exception No. 2.

### 370.10 Marking

Each section of cablebus shall be marked with the manufacturer's name or trade designation and the maximum diameter, number, voltage rating, and ampacity of the conductors to be installed. Markings shall be located so as to be visible after installation.

## ARTICLE 372 Cellular Concrete Floor Raceways

### Contents

- 372.1 Scope

- 372.10 Size of Conductors
- 372.11 Maximum Number of Conductors
- 372.12 Splices and Taps
- 372.13 Discontinued Outlets
- 372.17 Ampacity of Conductors

### 372.1 Scope

This article covers cellular concrete floor raceways, the hollow spaces in floors constructed of precast cellular concrete slabs, together with suitable metal fittings designed to provide access to the floor cells.

Cellular concrete floor raceways are a form of floor deck construction commonly used in high-rise office buildings. This construction method is very similar in design, application, and adaptation to cellular metal floor raceways. Basically, this wiring method consists of floor cells (that are part of the structural floor system), header ducts laid at right angles to the cells and used to carry conductors from cabinets to cells, and junction boxes.

### 372.2 Definitions

**Cell.** A single, enclosed tubular space in a floor made of precast cellular concrete slabs, the direction of the cell being parallel to the direction of the floor member.

**Header.** Transverse metal raceways for electrical conductors, providing access to predetermined cells of a precast cellular concrete floor, thereby permitting the installation of electrical conductors from a distribution center to the floor cells.

### 372.4 Uses Not Permitted

Conductors shall not be installed in precast cellular concrete floor raceways as follows:

- (1) Where subject to corrosive vapor
- (2) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (3) In commercial garages, other than for supplying ceiling outlets or extensions to the area below the floor but not above

Informational Note: See 300.8 for installation of conductors with other systems.

Section 300.8 prohibits the installation of electrical conductors in raceways or cable trays containing any pipes, tubes, or other means for carrying steam, water, air, gas, or drainage or for any service other than electrical.

### 372.5 Header

The header shall be installed in a straight line at right angles to the cells. The header shall be mechanically secured to the top of the precast cellular concrete floor. The end joints shall be closed by a metal closure fitting and sealed against the entrance of concrete. The header shall be electrically continuous throughout its entire length and shall be electrically bonded to the enclosure of the distribution center.

### 372.6 Connection to Cabinets and Other Enclosures

Connections from headers to cabinets and other enclosures shall be made by means of listed metal raceways and listed fittings.

### 372.7 Junction Boxes

Junction boxes shall be leveled to the floor grade and sealed against the free entrance of water or concrete. Junction boxes shall be of metal and shall be mechanically and electrically continuous with the header.

### 372.8 Markers

A suitable number of markers shall be installed for the future location of cells.

### 372.9 Inserts

Inserts shall be leveled and sealed against the entrance of concrete. Inserts shall be of metal and shall be fitted with grounded-type receptacles. A grounding conductor shall connect the insert receptacles to a positive ground connection provided on the header. Where cutting through the cell wall for setting inserts or other purposes (such as providing access openings between header and cells), chips and other dirt shall not be allowed to remain in the raceway, and the tool used shall be designed so as to prevent the tool from entering the cell and damaging the conductors.

### 372.10 Size of Conductors

No conductor larger than 1/0 AWG shall be installed, except by special permission.

### 372.11 Maximum Number of Conductors

The combined cross-sectional area of all conductors or cables shall not exceed 40 percent of the cross-sectional area of the cell or header.

### 372.12 Splices and Taps

Splices and taps shall be made only in header access units or junction boxes. A continuous unbroken conductor connecting the individual outlets is not a splice or tap.

### 372.13 Discontinued Outlets

When an outlet is abandoned, discontinued, or removed, the sections of circuit conductors supplying the outlet shall be removed from the raceway. No splices or reinsulated conductors, such as would be the case of abandoned outlets on loop wiring, shall be allowed in raceways.

### 372.17 Ampacity of Conductors

The ampacity adjustment factors, provided in 310.15(B)(3), shall apply to conductors installed in cellular concrete floor raceways.

## ARTICLE 374 Cellular Metal Floor Raceways

### Contents

- 374.1 Scope
- 374.2 Definitions
- 374.3 Uses Not Permitted
- I. Installation
  - 374.4 Size of Conductors
  - 374.5 Maximum Number of Conductors in Raceway

  - 374.11 Connection to Cabinets and Extensions from Cells
  - 374.17 Ampacity of Conductors
- II. Construction Specifications
  - 374.100 General

### 374.1 Scope

This article covers the use and installation requirements for cellular metal floor raceways.

Cellular metal floor raceways, as shown in Exhibit 374.1, are a form of metal floor deck construction designed for use in steel-frame buildings and consisting of sheet metal formed into shapes that are combined to form cells or raceways. The cells extend across the building and, depending on the structural strength required, can have various shapes and sizes.

**EXHIBIT 374.1** An artist's rendition of a cross section of cellular metal floor raceway system. (Courtesy of H.H. Robertson Floor Systems)

Connections to the cells are made by means of headers extending across the cells and connecting only to those cells to be used as raceways for the conductors. Two or three separate headers, connecting to different sets of cells, may be used for different systems, such as light and power, signaling, and communications systems.

### 374.2 Definitions

**Cellular Metal Floor Raceway.** The hollow spaces of cellular metal floors, together with suitable fittings, that may be approved as enclosures for electrical conductors.

**Cell.** A single enclosed tubular space in a cellular metal floor member, the axis of the cell being parallel to the axis of the metal floor member.

**Header.** A transverse raceway for electrical conductors, providing access to predetermined cells of a cellular metal floor, thereby permitting the installation of electrical conductors from a distribution center to the cells.

### 374.3 Uses Not Permitted

Conductors shall not be installed in cellular metal floor raceways as follows:

- (1) Where subject to corrosive vapor
- (2) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (3) In commercial garages, other than for supplying ceiling outlets or extensions to the area below the floor but not above

Informational Note: See 300.8 for installation of conductors with other systems.

Section 300.8 prohibits the installation of electrical conductors in raceways or cable trays containing any pipes, tubes, or other carriers of steam, water, air, gas, or drainage, or for any service other than electrical.

## I. Installation

### 374.4 Size of Conductors

No conductor larger than 1/0 AWG shall be installed, except by special permission.

### 374.5 Maximum Number of Conductors in Raceway

The combined cross-sectional area of all conductors or cables shall not exceed 40 percent of the interior cross-sectional area of the cell or header.

### 374.6 Splices and Taps

Splices and taps shall be made only in header access units or junction boxes.

For the purposes of this section, so-called loop wiring (continuous unbroken conductor connecting the individual outlets) shall not be considered to be a splice or tap.

### 374.7 Discontinued Outlets

When an outlet is abandoned, discontinued, or removed, the sections of circuit conductors supplying the outlet shall be removed from the raceway. No splices or reinsulated conductors, such as would be the case with abandoned outlets on loop wiring, shall be allowed in raceways.

### 374.8 Markers

A suitable number of markers shall be installed for locating cells in the future.

The markers required by 374.8 are typically brass flat-head screws set into the top side of the cells and adjusted so that their heads are flush with the floor finish and are exposed in order to aid in the location of cells for future installations.

### 374.9 Junction Boxes

Junction boxes shall be leveled to the floor grade and sealed against the free entrance of water or concrete. Junction boxes used with these raceways shall be of metal and shall be electrically continuous with the raceway.

Connections to wall outlets are to be made with metal raceways unless there are provisions for equipment grounding termination, as required by 374.11. Installation instructions are supplied by the manufacturer for use by the general contractor, erector, electrical contractor, inspector, and others concerned with the installation.

### 374.10 Inserts

Inserts shall be leveled to the floor grade and sealed against the entrance of concrete. Inserts shall be of metal and shall be electrically continuous with the raceway. In cutting through the cell wall and setting inserts, chips and other dirt shall not be allowed to remain in the raceway, and tools shall be used that are designed to prevent the tool from entering the cell and damaging the conductors.

### 374.11 Connection to Cabinets and Extensions from Cells

Connections between raceways and distribution centers and wall outlets shall be made by means of liquidtight flexible metal conduit, flexible metal conduit where not installed in

concrete, rigid metal conduit, intermediate metal conduit, electrical metallic tubing, or approved fittings. Where there are provisions for the termination of an equipment grounding conductor, nonmetallic conduit, electrical nonmetallic tubing, or liquidtight flexible nonmetallic conduit shall be permitted. Where installed in concrete, liquidtight flexible nonmetallic conduit shall be listed and marked for direct burial.

**Informational Note:** Liquidtight flexible metal conduit and liquidtight flexible nonmetallic conduit that is suitable for installation in concrete is listed and marked for direct burial.

### 374.17 Ampacity of Conductors

The ampacity adjustment factors in 310.15(B)(3) shall apply to conductors installed in cellular metal floor raceways.

## II. Construction Specifications

### 374.100 General

Cellular metal floor raceways shall be constructed so that adequate electrical and mechanical continuity of the complete system will be secured. They shall provide a complete enclosure for the conductors. The interior surfaces shall be free from burrs and sharp edges, and surfaces over which conductors are drawn shall be smooth. Suitable bushings or fittings having smooth rounded edges shall be provided where conductors pass.

376.120 Marking

## I. General

### 376.1 Scope

This article covers the use, installation, and construction specifications for metal wireways and associated fittings.

Wireways are sheet-metal enclosures equipped with hinged or removable covers and are manufactured in 1-ft to 10-ft lengths and various widths and depths. Couplings, elbows, end plates, and accessories such as T and X fittings are available. Unlike auxiliary gutters, which are not permitted to extend more than 30 ft from the equipment they supplement, wireways may be run throughout an entire area. See the commentary following 366.2 for more information on the differences between wireways and auxiliary gutters.

### 376.2 Definition

**Metal Wireways.** Sheet metal troughs with hinged or removable covers for housing and protecting electrical wires and cable and in which conductors are laid in place after the wireway has been installed as a complete system.

## II. Installation

### 376.10 Uses Permitted

The use of metal wireways shall be permitted as follows:

- (1) For exposed work.
- (2) In any hazardous (classified) location, as permitted by other articles in this Code.
- (3) In wet locations where wireways are listed for the purpose.
- (4) In concealed spaces as an extension that passes transversely through walls, if the length passing through the wall is unbroken. Access to the conductors shall be maintained on both sides of the wall.

### 376.12 Uses Not Permitted

Metal wireways shall not be used in the following:

- (1) Where subject to severe physical damage
- (2) Where subject to severe corrosive environments

### 376.21 Size of Conductors

No conductor larger than that for which the wireway is designed shall be installed in any wireway.

### 376.22 Number of Conductors and Ampacity

The number of conductors and their ampacity shall comply with 376.22(A) and (B).

The requirements of 376.22(A) for the number of conductors are as follows:

- All conductors count in determining wireway fill.
- Total conductor fill must not exceed 20 percent of the wireway.

The conductor ampacity requirements of 376.22(B) are as follows:

- Conductor ampacity is determined according to 310.15.
- Where the quantity of current-carrying conductors does not exceed 30, the adjustment factors of 310.15(B)(3)(a) do not apply.
- Where the quantity of current-carrying conductors does exceed 30, the adjustment factors of 310.15(B)(3)(a) do apply.
- Neutral conductors are determined to be current-carrying conductors according to 310.15(B)(5).
- Signaling circuit conductors are not considered current-carrying conductors.
- Conductors used only for motor-starting duty as limited by 376.22(B) are not considered current-carrying conductors.

The following installation example consists of a wireway with 26 current-carrying conductors; therefore, the adjustment factors of 310.15(B)(3)(a) do not apply.

#### Calculation Example

A wireway contains 26 conductors: ten 3/0 AWG XHHW-2, three 6 AWG THWN, three 8 AWG THHN, and ten 12 AWG THHN. Find the minimum standard size wireway required by Article 376.

#### Solution

Conductor Type and Size	Quantity	Individual Area* (in. <sup>2</sup> )	Total Area (in. <sup>2</sup> )
3/0 AWG, XHHW-2	10 ×	0.2642	= 2.6420
6 AWG, THWN	3 ×	0.0507	= 0.1521
8 AWG, THHN	3 ×	0.0366	= 0.1098
12 AWG, THHN	10 ×	0.0133	= 0.1330
Total area occupied by conductors			3.0369
Minimum wireway area required:			
$3.0369 \text{ in.}^2 \div 20\% \text{ fill} = 15.1845 \text{ in.}^2$			
Minimum size square wireway required:			
$15.1845 \text{ in.}^2 = 3.9 \text{ in.} \times 3.9 \text{ in. or } 4 \text{ in.} \times 4 \text{ in. wireway}$			

\*Individual area dimensions of conductors are from Chapter 9, Table 5.

**(A) Cross-Sectional Areas of Wireway.** The sum of the cross-sectional areas of all contained conductors at any cross section of a wireway shall not exceed 20 percent of the interior cross-sectional area of the wireway.

**(B) Adjustment Factors.** The adjustment factors in 310.15(B)(3)(a) shall be applied only where the number of current-carrying conductors, including neutral conductors classified as current-carrying under the provisions of 310.15(B)(5), exceeds 30. Conductors for signaling circuits or controller conductors between a motor and its starter and used only for starting duty shall not be considered as current-carrying conductors.

### 376.23 Insulated Conductors

Insulated conductors installed in a metallic wireway shall comply with 376.23(A) and (B).

**(A) Deflected Insulated Conductors.** Where insulated conductors are deflected within a metallic wireway, either at the ends or where conduits, fittings, or other raceways or cables enter or leave the metallic wireway, or where the direction of the metallic wireway is deflected greater than 30 degrees, dimensions corresponding to one wire per terminal in Table 312.6(A) shall apply.

The intent of 376.23 is to provide adequate space for installing and bending conductors without damaging the conductor insulation.

**(B) Metallic Wireways Used as Pull Boxes.** Where insulated conductors 4 AWG or larger are pulled through a wireway, the distance between raceway and cable entries enclosing the same conductor shall not be less than that required by 314.28(A)(1) for straight pulls and 314.28(A)(2) for angle pulls. When transposing cable size into raceway size, the minimum metric designator (trade size) raceway required for the number and size of conductors in the cable shall be used.

The requirements in 376.23(B) ensure that where wireways are used as pull boxes, the same minimum dimension requirements associated with raceway entries of pull boxes apply.

## 376.30 Securing and Supporting

Metal wireways shall be supported in accordance with 376.30(A) and (B).

**(A) Horizontal Support.** Wireways shall be supported where run horizontally at each end and at intervals not to

exceed 1.5 m (5 ft) or for individual lengths longer than 1.5 m (5 ft) at each end or joint, unless listed for other support intervals. The distance between supports shall not exceed 3 m (10 ft).

**(B) Vertical Support.** Vertical runs of wireways shall be securely supported at intervals not exceeding 4.5 m (15 ft) and shall not have more than one joint between supports. Adjoining wireway sections shall be securely fastened together to provide a rigid joint.

### 376.56 Splices, Taps, and Power Distribution Blocks

**(A) Splices and Taps.** Splices and taps shall be permitted within a wireway, provided they are accessible. The conductors, including splices and taps, shall not fill the wireway to more than 75 percent of its area at that point.

Conductors in wireways can be accessed through hinged or removable covers. See 376.22 and the associated commentary example regarding the number of conductors permitted.

#### **(B) Power Distribution Blocks.**

Where power distribution blocks are placed within metal wireways, additional precautions are necessary as required by 376.56(B)(1) through (B)(4). With the use of listed terminal blocks, additional field product evaluation is not necessary.

**(1) Installation.** Power distribution blocks installed in metal wireways shall be listed.

**(2) Size of Enclosure.** In addition to the wiring space requirement in 376.56(A), the power distribution block shall be installed in a wireway with dimensions not smaller than specified in the installation instructions of the power distribution block.

**(3) Wire Bending Space.** Wire bending space at the terminals of power distribution blocks shall comply with 312.6(B).

**(4) Live Parts.** Power distribution blocks shall not have uninsulated live parts exposed within a wireway, whether or not the wireway cover is installed.

### 376.58 Dead Ends

Dead ends of metal wireways shall be closed.

### 376.70 Extensions from Metal Wireways

Extensions from wireways shall be made with cord pendants installed in accordance with 400.10 or with any wiring

method in Chapter 3 that includes a means for equipment grounding. Where a separate equipment grounding conductor is employed, connection of the equipment grounding conductors in the wiring method to the wireway shall comply with 250.8 and 250.12.

Extensions from wireways using metal raceways, metal-sheathed cables, and nonmetallic-sheathed cables are made through knockouts provided on the wireway or field punched. Rigid polyvinyl chloride conduit electrical nonmetallic tubing, and liquidtight flexible nonmetallic conduit may also be used. Cables and nonmetallic raceways as well as the wireway must include a means for ensuring an effective continuation of the equipment grounding conductor. Sections of wireways, including accessory fittings (elbows, endplates, flanges, etc.), are bolted together, ensuring a rigid mechanical and electrical connection.

## III. Construction Specifications

### 376.100 Construction

**(A) Electrical and Mechanical Continuity.** Wireways shall be constructed and installed so that electrical and mechanical continuity of the complete system are assured.

**(B) Substantial Construction.** Wireways shall be of substantial construction and shall provide a complete enclosure for the contained conductors. All surfaces, both interior and exterior, shall be suitably protected from corrosion. Corner joints shall be made tight, and where the assembly is held together by rivets, bolts, or screws, such fasteners shall be spaced not more than 300 mm (12 in.) apart.

**(C) Smooth Rounded Edges.** Suitable bushings, shields, or fittings having smooth, rounded edges shall be provided where conductors pass between wireways, through partitions, around bends, between wireways and cabinets or junction boxes, and at other locations where necessary to prevent abrasion of the insulation of the conductors.

**(D) Covers.** Covers shall be securely fastened to the wireway.

The intent of 376.100(A) through (D) is to aid in construction of one of a kind or custom-made wireways and fittings.

### 376.120 Marking

Metal wireways shall be so marked that their manufacturer's name or trademark will be visible after installation.

## ARTICLE 378

  - 378.44 Expansion Fittings
  - 378.56 Splices and Taps
  - 378.58 Dead Ends
  - 378.60 Grounding
  - 378.70 Extensions from Nonmetallic Wireways
- III. Construction Specifications
  - 378.120 Marking

#### I. General

##### 378.1 Scope

This article covers the use, installation, and construction specifications for nonmetallic wireways and associated fittings.

Nonmetallic wireways are troughs with removable covers in which conductors are laid after the wireway has been installed as a complete system. The wireway must be installed on the surface of the structure, not concealed. It is allowed to pass through walls, provided that an unbroken length passes through the wall.

##### 378.2 Definition

**Nonmetallic Wireways.** Flame retardant, nonmetallic troughs with removable covers for housing and protecting electrical wires and cables in which conductors are laid in place after the wireway has been installed as a complete system.

##### 378.6 Listing Requirements

Nonmetallic wireways and associated fittings shall be listed.

#### II. Installation

##### 378.10 Uses Permitted

The use of nonmetallic wireways shall be permitted in the following:

- (1) Only for exposed work, except as permitted in 378.10(4).
- (2) Where subject to corrosive environments where identified for the use.
- (3) In wet locations where listed for the purpose.

Informational Note: Extreme cold may cause nonmetallic wireways to become brittle and therefore more susceptible to damage from physical contact.

- (4) As extensions to pass transversely through walls if the length passing through the wall is unbroken. Access to the conductors shall be maintained on both sides of the wall.

##### 378.12 Uses Not Permitted

Nonmetallic wireways shall not be used in the following:

- (1) Where subject to physical damage
- (2) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (3) Where exposed to sunlight unless listed and marked as suitable for the purpose
- (4) Where subject to ambient temperatures other than those for which nonmetallic wireway is listed
- (5) For conductors whose insulation temperature limitations would exceed those for which the nonmetallic wireway is listed

##### 378.21 Size of Conductors

No conductor larger than that for which the nonmetallic wireway is designed shall be installed in any nonmetallic wireway.

##### 378.22 Number of Conductors

The sum of cross-sectional areas of all contained conductors at any cross section of the nonmetallic wireway shall not exceed 20 percent of the interior cross-sectional area of the nonmetallic wireway. Conductors for signaling circuits or controller conductors between a motor and its starter and used only for starting duty shall not be considered as current-carrying conductors.

The **adjustment** factors specified in 310.15(B)(3)(a) shall be applicable to the current-carrying conductors up to and including the 20 percent fill specified above.

##### 378.23 Insulated Conductors

Insulated conductors installed in a nonmetallic wireway shall comply with 378.23(A) and (B).

**(A) Deflected Insulated Conductors.** Where insulated conductors are deflected within a nonmetallic wireway, either at the ends or where conduits, fittings, or other raceways or cables enter or leave the nonmetallic wireway, or where the direction of the nonmetallic wireway is deflected greater than 30 degrees, dimensions corresponding to one wire per terminal in Table 312.6(A) shall apply.

**(B) Nonmetallic Wireways Used as Pull Boxes.** Where insulated conductors 4 AWG or larger are pulled through a wireway, the distance between raceway and cable entries enclosing the same conductor shall not be less than that required in 314.28(A)(1) for straight pulls and in 314.28(A)(2) for angle pulls. When transposing cable size into raceway size, the minimum metric designator (trade size) raceway required for the number and size of conductors in the cable shall be used.

The intent of 378.23 is to provide adequate space for installing and bending conductors without damaging the conductor insulation. Section 378.23(A) ensures that the Table 312.6(A) column of one wire per terminal is used. Section 378.23(B) requires that the same adequate space requirements that apply to conduits also apply to cables as they enter a wireway. Finally, where wireways are used as pull boxes, the same minimum dimension requirements associated with raceway entries of pull boxes apply.

### 378.30 Securing and Supporting

Nonmetallic wireway shall be supported in accordance with 378.30(A) and (B).

**(A) Horizontal Support.** Nonmetallic wireways shall be supported where run horizontally at intervals not to exceed 900 mm (3 ft), and at each end or joint, unless listed for other support intervals. In no case shall the distance between supports exceed 3 m (10 ft).

**(B) Vertical Support.** Vertical runs of nonmetallic wireway shall be securely supported at intervals not exceeding 1.2 m (4 ft), unless listed for other support intervals, and shall not have more than one joint between supports. Adjoining nonmetallic wireway sections shall be securely fastened together to provide a rigid joint.

### 378.44 Expansion Fittings

Expansion fittings for nonmetallic wireway shall be provided to compensate for thermal expansion and contraction where the length change is expected to be 6 mm (0.25 in.) or greater in a straight run.

Informational Note: See Table 352.44 for expansion characteristics of PVC conduit. The expansion characteristics of PVC nonmetallic wireway are identical.

### 378.56 Splices and Taps

Splices and taps shall be permitted within a nonmetallic wireway, provided they are accessible. The conductors, including splices and taps, shall not fill the nonmetallic wireway to more than 75 percent of its area at that point.

### 378.58 Dead Ends

Dead ends of nonmetallic wireway shall be closed using listed fittings.

### 378.60 Grounding

Where equipment grounding is required, a separate equipment grounding conductor shall be installed in the nonmetallic wireway. A separate equipment grounding conductor shall not be required where the grounded conductor is used to ground equipment as permitted in 250.142.

### 378.70 Extensions from Nonmetallic Wireways

Extensions from nonmetallic wireway shall be made with cord pendants or any wiring method of Chapter 3. A separate equipment grounding conductor shall be installed in, or an equipment grounding connection shall be made to, any of the wiring methods used for the extension.

## III. Construction Specifications

### 378.120 Marking

Nonmetallic wireways shall be marked so that the manufacturer's name or trademark and interior cross-sectional area in square inches shall be visible after installation. Marking for limited smoke shall be permitted on the nonmetallic wireways that have limited smoke-producing characteristics.

  - 380.10 Uses Permitted
  - 380.12 Uses Not Permitted
  - 380.23 Insulated Conductors
    - (A) Deflected Insulated Conductors
    - (B) Multioutlet Assemblies Used as Pull Boxes
  - 380.76 Metal Multioutlet Assembly Through Dry Partitions

This article was reorganized for the 2011 *Code* to follow the format of other Chapter 3 Articles.

## I. General

### 380.1 Scope

This article covers the use and installation requirements for multioutlet assemblies.

Multioutlet assemblies are metal or nonmetallic raceways that are usually surface mounted and designed to contain branch-circuit conductors and receptacles. Exhibit 380.1 provides an illustration of a multioutlet assembly. Receptacles may be spaced at desired intervals and may be assembled at the factory or in the field. See 220.14(H) and Exhibit 220.4 for load calculations.

**EXHIBIT 380.1** A typical multioutlet assembly shown in assembly form.

Informational Note: See the definition of multioutlet assembly in Article 100.

## II. Installation

### 380.10 Uses Permitted

The use of a multioutlet assembly shall be permitted in dry locations.

### 380.12 Uses Not Permitted

A multioutlet assembly shall not be installed as follows:

- (1) Where concealed, except that it shall be permissible to surround the back and sides of a metal multioutlet assembly by the building finish or recess a nonmetallic multioutlet assembly in a baseboard
- (2) Where subject to severe physical damage
- (3) Where the voltage is 300 volts or more between conductors unless the assembly is of metal having a thickness of not less than 1.02 mm (0.040 in.)
- (4) Where subject to corrosive vapors
- (5) In hoistways
- (6) In any hazardous (classified) location, except as permitted by other articles in this Code

### 380.23 Insulated Conductors

For field assembled multioutlet assemblies, insulated conductors shall comply with 380.23(A) and (B).

**(A) Deflected Insulated Conductors.** Where insulated conductors are deflected within a multioutlet assembly, either at the ends or where conduits, fittings, or other raceways or cables enter or leave the multioutlet assembly, or where the direction of the multioutlet assembly is deflected greater than 30 degrees, dimensions corresponding to one wire per terminal in Table 312.6(A) shall apply.

**(B) Multioutlet Assemblies Used as Pull Boxes.** Where insulated conductors 4 AWG or larger are pulled through a multioutlet assembly, the distance between raceway and cable entries enclosing the same conductor shall not be less than that required by 314.28(A)(1) for straight pulls and 314.28(A)(2) for angle pulls. When transposing cable size into raceway size, the minimum metric designator (trade size) raceway required for the number and size of conductors in the cable shall be used.

This section was added for the 2011 Code. It provides safeguards to prevent overfill with a limitation of the number of conductors that can be installed in multioutlet assemblies. For deflected insulated conductors, dimensions corresponding to the minimum width of wiring gutters must be maintained.

Where a multioutlet assembly is used as a pull box for insulated conductors of 4 AWG or larger, the distance between the raceway and the cable entries enclosing the conductor must not be less than eight times the trade size or metric designator of the raceway for straight pulls. For angle pulls, the distance must be six times the trade size or metric designator of the raceway.

### 380.76 Metal Multioutlet Assembly Through Dry Partitions

It shall be permissible to extend a metal multioutlet assembly through (not run within) dry partitions if arrangements are made for removing the cap or cover on all exposed portions and no outlet is located within the partitions.

## I. General

### 382.1 Scope

This article covers the use, installation, and construction specifications for nonmetallic extensions.

### 382.2 Definitions

**Concealable Nonmetallic Extension.** A listed assembly of two, three, or four insulated circuit conductors within a non-metallic jacket, an extruded thermoplastic covering, or a sealed nonmetallic covering. The classification includes surface extensions intended for mounting directly on the surface of walls or ceilings, and concealed with paint, texture, joint compound, plaster, wallpaper, tile, wall paneling, or other similar materials.

**Nonmetallic Extension.** An assembly of two insulated conductors within a nonmetallic jacket or an extruded thermoplastic covering. The classification includes surface extensions intended for mounting directly on the surface of walls or ceilings.

### 382.6 Listing Requirements

Concealable nonmetallic extensions and associated fittings and devices shall be listed. The starting/source tap device for

the extension shall contain and provide the following protection for all load-side extensions and devices.

- (1) Supplementary overcurrent protection
- (2) Level of protection equivalent to a Class A GFCI
- (3) Level of protection equivalent to a portable GFCI
- (4) Line and load-side miswire protection
- (5) Provide protection from the effects of arc faults

## II. Installation

### 382.10 Uses Permitted

Nonmetallic extensions shall be permitted only in accordance with 382.10(A), (B), and (C).

**(A) From an Existing Outlet.** The extension shall be from an existing outlet on a 15- or 20-ampere branch circuit. Where a concealable nonmetallic extension originates from a non-grounding-type receptacle, the installation shall comply with 250.130(C), 406.4(D)(3)(b), or 406.4(D)(3)(c).

**(B) Exposed and in a Dry Location.** The extension shall be run exposed, or concealed as permitted in 382.15, and in a dry location.

**(C) Residential or Offices.** For nonmetallic surface extensions mounted directly on the surface of walls or ceilings, the building shall be occupied for residential or office purposes and shall not exceed three floors abovegrade. Where identified for the use, concealable nonmetallic extensions shall be permitted more than three floors abovegrade.

Informational Note No. 1: See 310.15(A)(3) for temperature limitation of conductors.

Informational Note No. 2: See 362.10 for definition of *First Floor*.

### 382.12 Uses Not Permitted

Nonmetallic extensions shall not be used as follows:

- (1) In unfinished basements, attics, or roof spaces
- (2) Where the voltage between conductors exceeds 150 volts for nonmetallic surface extensions and 300 volts for aerial cable
- (3) Where subject to corrosive vapors
- (4) Where run through a floor or partition, or outside the room in which it originates

### 382.15 Exposed

**(A) Nonmetallic Extensions.** One or more extensions shall be permitted to be run in any direction from an existing outlet, but not on the floor or within 50 mm (2 in.) from the floor.

**(B) Concealable Nonmetallic Extensions.** Where identified for the use, nonmetallic extensions shall be permitted to be concealed with paint, texture, concealing compound,

plaster, wallpaper, tile, wall paneling, or other similar materials and installed in accordance with 382.15(A).

### 382.26 Bends

**(A) Nonmetallic Extensions.** A bend that reduces the normal spacing between the conductors shall be covered with a cap to protect the assembly from physical damage.

**(B) Concealable Nonmetallic Extensions.** Concealable extensions shall be permitted to be folded back over themselves and flattened as required for installation.

### 382.30 Securing and Supporting

**(A) Nonmetallic Extensions.** Nonmetallic surface extensions shall be secured in place by approved means at intervals not exceeding 200 mm (8 in.), with an allowance for 300 mm (12 in.) to the first fastening where the connection to the supplying outlet is by means of an attachment plug. There shall be at least one fastening between each two adjacent outlets supplied. An extension shall be attached to only woodwork or plaster finish and shall not be in contact with any metal work or other conductive material other than with metal plates on receptacles.

**(B) Concealable Nonmetallic Extensions.** All surface-mounted concealable nonmetallic extension components shall be firmly anchored to the wall or ceiling using an adhesive or mechanical anchoring system identified for this use.

### 382.40 Boxes and Fittings

Each run shall terminate in a fitting, connector, or box that covers the end of the assembly. All fittings, connectors, and devices shall be of a type identified for the use.

### 382.42 Devices

**(A) Receptacles.** All receptacles, receptacle housings, and self-contained devices used with concealable nonmetallic extensions shall be identified for this use.

**(B) Receptacles and Housings.** Receptacle housings and self-contained devices designed either for surface or for recessed mounting shall be permitted for use with concealable nonmetallic extensions. Receptacle housings and self-contained devices shall incorporate means for facilitating entry and termination of concealable nonmetallic extensions and for electrically connecting the housing or device. Receptacle and self-contained devices shall comply with 406.4. Power and communications outlets installed together in common housing shall be permitted in accordance with 800.133(A)(1)(c), Exception No. 2.

### 382.56 Splices and Taps

Extensions shall consist of a continuous unbroken length of the assembly, without splices, and without exposed conduc-

tors between fittings, connectors, or devices. Taps shall be permitted where approved fittings completely covering the tap connections are used. Aerial cable and its tap connectors shall be provided with an approved means for polarization. Receptacle-type tap connectors shall be of the locking type.

## III. Construction Specifications (Concealable Nonmetallic Extensions Only)

### 382.100 Construction

Concealable nonmetallic extensions shall be a multilayer flat conductor design consisting of a center ungrounded conductor enclosed by a sectioned grounded conductor, and an overall sectioned grounding conductor.

### 382.104 Flat Conductors

Concealable nonmetallic extensions shall be constructed, using flat copper conductors equivalent to 14 AWG or 12 AWG conductor sizes, and constructed per 382.104(A), (B), and (C).

**(A) Ungrounded Conductor (Center Layer).** The ungrounded conductor shall consist of one or more ungrounded flat conductor(s) enclosed in accordance with 382.104(B) and (C) and identified in accordance with 310.110(C).

**(B) Grounded Conductor (Inner Sectioned Layers).** The grounded conductor shall consist of two sectioned inner flat conductors that enclose the center ungrounded conductor(s). The sectioned grounded conductor shall be enclosed by the sectioned grounding conductor and identified in accordance with 200.6.

**(C) Grounding Conductor (Outer Sectioned Layers).** The grounding conductor shall consist of two overall sectioned conductors that enclose the grounded conductor and ungrounded conductor(s) and shall comply with 250.4(A)(5). The grounding conductor layers shall be identified by any one of the following methods:

- (1) As permitted in 250.119
- (2) A clear covering
- (3) One or more continuous green stripes or hash marks
- (4) The term "Equipment Ground" printed at regular intervals throughout the cable

Multilayer flat conductor design is a complete assembly of branch-circuit conductors. This manufactured assembly is thinner than a business card and yet flexible enough to bend to any angle required for a customized installation.

**EXHIBIT 382.1** One example of multilayer flat conductor cable assembly used as a nonmetallic extension in compliance with Article 382. (Courtesy of FlatWire Technologies, a division of Southwire®)

Exhibit 382.1 is one example of a concealable nonmetallic extension circuit conductor assembly of flat conductors meeting the requirement of Article 382.

A multilayer flat wire cable assembly is a five-layer design for circuit integrity and protection. Flat sectioned equipment grounding conductor layers fully encase the ungrounded conductor and grounded conductor layers of the cable. By design, any penetration in the flat wire cable assembly will penetrate the equipment grounding conductor layer first, then the grounded conductor layer, then the ungrounded conductor layer. A penetration will result in a short circuit between the three conductors described that will immediately trip the overcurrent protection device, causing automatic disconnection of the circuit.

### 382.112 Insulation

The ungrounded and grounded flat conductor layers shall be individually insulated and comply with 310.15(A)(3). The grounding conductor shall be covered or insulated.

### 382.120 Marking

**(A) Cable.** Concealable nonmetallic extensions shall be clearly and durably marked on both sides at intervals of not more than 610 mm (24 in.) with the information required by 310.120(A) and with the following additional information:

- (1) Material of conductors
- (2) Maximum temperature rating
- (3) Ampacity

**(B) Conductor Identification.** Conductors shall be clearly and durably identified on both sides throughout their length as specified in 382.104.

## I. General

### 384.1 Scope

This article covers the use, installation, and construction specifications of strut-type channel raceway.

### 384.2 Definition

**Strut-Type Channel Raceway.** A metallic raceway that is intended to be mounted to the surface of or suspended from a structure, with associated accessories for the installation of electrical conductors and cables.

### 384.6 Listing Requirements

Strut-type channel raceways, closure strips, and accessories shall be listed and identified for such use.

## II. Installation

### 384.10 Uses Permitted

The use of strut-type channel raceways shall be permitted in the following:

- (1) Where exposed.
- (2) In dry locations.
- (3) In locations subject to corrosive vapors where protected by finishes judged suitable for the condition.

- (4) Where the voltage is 600 volts or less.
- (5) As power poles.
- (6) In Class I, Division 2 hazardous (classified) locations as permitted in 501.10(B)(3).
- (7) As extensions of unbroken lengths through walls, partitions, and floors where closure strips are removable from either side and the portion within the wall, partition, or floor remains covered.
- (8) Ferrous channel raceways and fittings protected from corrosion solely by enamel shall be permitted only indoors.

The installation shown in Exhibit 384.1 is typical of how a strut-type channel raceway can be used.

**EXHIBIT 384.1** An example of a strut-type channel raceway using accessories to support and supply power to luminaires.

### 384.12 Uses Not Permitted

Strut-type channel raceways shall not be used as follows:

- (1) Where concealed.
- (2) Ferrous channel raceways and fittings protected from corrosion solely by enamel shall not be permitted where subject to severe corrosive influences.

### 384.21 Size of Conductors

No conductor larger than that for which the raceway is listed shall be installed in strut-type channel raceways.

### 384.22 Number of Conductors

The number of conductors permitted in strut-type channel raceways shall not exceed the percentage fill using Table 384.22 and applicable cross-sectional area of specific types and sizes of wire given in the tables in Chapter 9.

The adjustment factors of 310.15(B)(3)(a) shall not apply to conductors installed in strut-type channel raceways where all of the following conditions are met:

- (1) The cross-sectional area of the raceway exceeds 2500 mm<sup>2</sup> (4 in.<sup>2</sup>).
- (2) The current-carrying conductors do not exceed 30 in number.

**TABLE 384.22** Channel Size and Inside Cross-Sectional Area

Size Channel	Area		40% Area*		25% Area†	
	in. <sup>2</sup>	mm <sup>2</sup>	in. <sup>2</sup>	mm <sup>2</sup>	in. <sup>2</sup>	mm <sup>2</sup>
1½ × 1⅜	0.887	572	0.355	229	0.222	143
1½ × 1	1.151	743	0.460	297	0.288	186
1½ × 1⅝	1.677	1076	0.671	433	0.419	270
1½ × 1⅞	2.028	1308	0.811	523	0.507	327
1½ × 2⅞	3.169	2045	1.267	817	0.792	511
1½ × 3¼	4.308	2780	1.723	1112	1.077	695
1½ × ¾	0.849	548	0.340	219	0.212	137
1½ × 1½	1.828	1179	0.731	472	0.457	295
1½ × 1⅞	2.301	1485	0.920	594	0.575	371
1½ × 3	3.854	2487	1.542	995	0.964	622

\*Raceways with external joiners shall use a 40 percent wire fill calculation to determine the number of conductors permitted.

†Raceways with internal joiners shall use a 25 percent wire fill calculation to determine the number of conductors permitted.

- (3) The sum of the cross-sectional areas of all contained conductors does not exceed 20 percent of the interior cross-sectional area of the strut-type channel raceways.

### 384.30 Securing and Supporting

**(A) Surface Mount.** A surface mount strut-type channel raceway shall be secured to the mounting surface with retention straps external to the channel at intervals not exceeding 3 m (10 ft) and within 900 mm (3 ft) of each outlet box, cabinet, junction box, or other channel raceway termination.

**(B) Suspension Mount.** Strut-type channel raceways shall be permitted to be suspension mounted in air with approved appropriate methods designed for the purpose at intervals not to exceed 3 m (10 ft) and within 900 mm (3 ft) of channel raceway terminations and ends.

### 384.56 Splices and Taps

Splices and taps shall be permitted in raceways that are accessible after installation by having a removable cover. The conductors, including splices and taps, shall not fill the raceway to more than 75 percent of its area at that point. All splices and taps shall be made by approved methods.

### 384.60 Grounding

Strut-type channel raceway enclosures providing a transition to or from other wiring methods shall have a means for connecting an equipment grounding conductor. Strut-type channel raceways shall be permitted as an equipment grounding conductor in accordance with 250.118(13). Where a snap-fit

metal cover for strut-type channel raceways is used to achieve electrical continuity in accordance with the listing, this cover shall not be permitted as the means for providing electrical continuity for a receptacle mounted in the cover.

### III. Construction Specifications

#### 384.100 Construction

Strut-type channel raceways and their accessories shall be of a construction that distinguishes them from other raceways. Raceways and their elbows, couplings, and other fittings shall be designed such that the sections can be electrically and mechanically coupled together and installed without subjecting the wires to abrasion. They shall comply with 384.100(A), (B), and (C).

**(A) Material.** Raceways and accessories shall be formed of steel, stainless steel, or aluminum.

**(B) Corrosion Protection.** Steel raceways and accessories shall be protected against corrosion by galvanizing or by an organic coating.

Informational Note: Enamel and PVC coatings are examples of organic coatings that provide corrosion protection.

**(C) Cover.** Covers of strut-type channel raceways shall be either metallic or nonmetallic.

#### 384.120 Marking

Each length of strut-type channel raceways shall be clearly and durably identified as required in the first sentence of 110.21.

  - 386.100 Construction

### I. General

#### 386.1 Scope

This article covers the use, installation, and construction specifications for surface metal raceways and associated fittings.

The installations shown in Exhibits 386.1 and 386.2 are examples of how surface metal raceway can be used to extend branch-circuit wiring to new switch-controlled outlets.

**EXHIBIT 386.1** An example of a surface metal raceway extending from an existing receptacle outlet.

**EXHIBIT 386.2** Use of surface metal raceway and associated fitting to supply ceiling-paddle fan and associated speed control.

### 386.2 Definition

**Surface Metal Raceway.** A metallic raceway that is intended to be mounted to the surface of a structure, with associated couplings, connectors, boxes, and fittings for the installation of electrical conductors.

### 386.6 Listing Requirements

Surface metal raceway and associated fittings shall be listed.

## II. Installation

### 386.10 Uses Permitted

The use of surface metal raceways shall be permitted in the following:

- (1) In dry locations.
- (2) In Class I, Division 2 hazardous (classified) locations as permitted in 501.10(B)(3).
- (3) Under raised floors, as permitted in 645.5(E)(2).
- (4) Extension through walls and floors. Surface metal raceway shall be permitted to pass transversely through dry walls, dry partitions, and dry floors if the length passing through is unbroken. Access to the conductors shall be maintained on both sides of the wall, partition, or floor.

### 386.12 Uses Not Permitted

Surface metal raceways shall not be used in the following:

- (1) Where subject to severe physical damage, unless otherwise approved
- (2) Where the voltage is 300 volts or more between conductors, unless the metal has a thickness of not less than 1.02 mm (0.040 in.) nominal
- (3) Where subject to corrosive vapors
- (4) In hoistways
- (5) Where concealed, except as permitted in 386.10

### 386.21 Size of Conductors

No conductor larger than that for which the raceway is designed shall be installed in surface metal raceway.

### 386.22 Number of Conductors or Cables

The number of conductors or cables installed in surface metal raceway shall not be greater than the number for which the raceway is designed. Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles.

The adjustment factors of 310.15(B)(3)(a) shall not apply to conductors installed in surface metal raceways where all of the following conditions are met:

- (1) The cross-sectional area of the raceway exceeds 2500 mm<sup>2</sup> (4 in.<sup>2</sup>).
- (2) The current-carrying conductors do not exceed 30 in number.

- (3) The sum of the cross-sectional areas of all contained conductors does not exceed 20 percent of the interior cross-sectional area of the surface metal raceway.

The number, type, and sizes of conductors permitted to be installed in a listed surface metal raceway are marked on the raceway or on the package in which it is shipped. This information is also available in detail in the manufacturer's catalog.

### 386.30 Securing and Supporting

Surface metal raceways shall be supported at intervals in accordance with the manufacturer's installation instructions.

### 386.56 Splices and Taps

Splices and taps shall be permitted in surface metal raceways having a removable cover that is accessible after installation. The conductors, including splices and taps, shall not fill the raceway to more than 75 percent of its area at that point. Splices and taps in surface metal raceways without removable covers shall be made only in boxes. All splices and taps shall be made by approved methods.

Taps of Type FC cable installed in surface metal raceway shall be made in accordance with 322.56(B).

### 386.60 Grounding

Surface metal raceway enclosures providing a transition from other wiring methods shall have a means for connecting an equipment grounding conductor.

As the example in Exhibit 386.3 shows, where a surface metal raceway is supplied by Type MC or NM cable, 386.60 requires a means (e.g., grounding terminal screw or lug) be available at the surface metal raceway for terminating the equipment grounding conductor provided within the cable.

### 386.70 Combination Raceways

When combination surface metallic raceways are used for both signaling and for lighting and power circuits, the different systems shall be run in separate compartments identified by stamping, imprinting, or color coding of the interior finish.

## III. Construction Specifications

### 386.100 Construction

Surface metal raceways shall be of such construction as will distinguish them from other raceways. Surface metal raceways and their elbows, couplings, and similar fittings shall be designed so that the sections can be electrically and me-

**EXHIBIT 386.3** An example of providing a means for terminating an equipment grounding conductor at a surface metal raceway.

chanically coupled together and installed without subjecting the wires to abrasion.

Where covers and accessories of nonmetallic materials are used on surface metal raceways, they shall be identified for such use.

## I. General

### 388.1 Scope

This article covers the use, installation, and construction specifications for surface nonmetallic raceways and associated fittings.

The installation shown in Exhibit 388.1 is typical of how a surface nonmetallic raceway can be used to supply power, CATV, and communications outlets.

**EXHIBIT 388.1** An example of a surface nonmetallic raceway supplying a receptacle outlet on the top and CATV and communications in the bottom compartment. (Courtesy of Legrand/Wiremold®)

### 388.2 Definition

**Surface Nonmetallic Raceway.** A nonmetallic raceway that is intended to be mounted to the surface of a structure, with associated couplings, connectors, boxes, and fittings for the installation of electrical conductors.

### 388.6 Listing Requirements

Surface nonmetallic raceway and associated fittings shall be listed.

## II. Installation

### 388.10 Uses Permitted

Surface nonmetallic raceways shall be permitted as follows:

- (1) The use of surface nonmetallic raceways shall be permitted in dry locations.

- (2) Extension through walls and floors shall be permitted. Surface nonmetallic raceway shall be permitted to pass transversely through dry walls, dry partitions, and dry floors if the length passing through is unbroken. Access to the conductors shall be maintained on both sides of the wall, partition, or floor.

### 388.12 Uses Not Permitted

Surface nonmetallic raceways shall not be used in the following:

- (1) Where concealed, except as permitted in 388.10(2)
- (2) Where subject to severe physical damage
- (3) Where the voltage is 300 volts or more between conductors, unless listed for higher voltage
- (4) In hoistways
- (5) In any hazardous (classified) location, except as permitted by other articles in this *Code*
- (6) Where subject to ambient temperatures exceeding those for which the nonmetallic raceway is listed
- (7) For conductors whose insulation temperature limitations would exceed those for which the nonmetallic raceway is listed

### 388.21 Size of Conductors

No conductor larger than that for which the raceway is designed shall be installed in surface nonmetallic raceway.

### 388.22 Number of Conductors or Cables

The number of conductors or cables installed in surface nonmetallic raceway shall not be greater than the number for which the raceway is designed. Cables shall be permitted to be installed where such use is not prohibited by the respective cable articles.

### 388.30 Securing and Supporting

Surface nonmetallic raceways shall be supported at intervals in accordance with the manufacturer's installation instructions.

### 388.56 Splices and Taps

Splices and taps shall be permitted in surface nonmetallic raceways having a cover capable of being opened in place that is accessible after installation. The conductors, including splices and taps, shall not fill the raceway to more than 75 percent of its area at that point. Splices and taps in surface nonmetallic raceways without covers capable of being opened in place shall be made only in boxes. All splices and taps shall be made by approved methods.

### 388.60 Grounding

Where equipment grounding is required, a separate equipment grounding conductor shall be installed in the raceway.

### 388.70 Combination Raceways

When combination surface nonmetallic raceways are used both for signaling and for lighting and power circuits, the different systems shall be run in separate compartments identified by stamping, imprinting, or color coding of the interior finish.

## III. Construction Specifications

### 388.100 Construction

Surface nonmetallic raceways shall be of such construction as will distinguish them from other raceways. Surface nonmetallic raceways and their elbows, couplings, and similar fittings shall be designed so that the sections can be mechanically coupled together and installed without subjecting the wires to abrasion.

Surface nonmetallic raceways and fittings are made of suitable nonmetallic material that is resistant to moisture and chemical atmospheres. It shall also be flame retardant, resistant to impact and crushing, resistant to distortion from heat under conditions likely to be encountered in service, and resistant to low-temperature effects.

### 388.120 Marking

Surface nonmetallic raceways that have limited smoke-producing characteristics shall be permitted to be so identified.

390.14 Inserts

390.15 Connections to Cabinets and Wall Outlets

390.17 Ampacity of Conductors

### 390.1 Scope

This article covers the use and installation requirements for underfloor raceways.

An underfloor raceway is a practical means of bringing light, power, and signal and communications systems to desks, work benches, or tables that are not located adjacent to wall space. This wiring method offers flexibility in layout where used with movable partitions and is commonly used in large retail stores and office buildings to supply power at any desired location.

Underfloor raceways are permitted beneath the surface of concrete, wood, or other flooring material. The wiring method between cabinets, raceway junction boxes, and outlet boxes may be rigid metal conduit, intermediate metal conduit, rigid PVC conduit, liquidtight flexible nonmetallic conduit, electrical nonmetallic tubing, or electrical metallic tubing. Flexible metal conduit may be used where not installed in concrete.

### 390.2 Definition

**Underfloor Raceway.** A raceway and associated components designed and intended for installation beneath or flush with the surface of a floor for the installation of cables and electrical conductors.

### 390.3 Use

**(A) Permitted.** The installation of underfloor raceways shall be permitted beneath the surface of concrete or other flooring material or in office occupancies where laid flush with the concrete floor and covered with linoleum or equivalent floor covering.

As Exhibit 390.1 illustrates, flat-top underfloor raceways over 4 in. wide and spaced less than 1 in. apart must be covered with at least 1½ in. of concrete.

Approved trench-type underfloor raceways may be installed flush with the floor surface, provided they have covers that provide protection at least equal to those of junction box covers. Approved metal flat-top underfloor raceways, if not over 4 in. wide, may be installed flush with a concrete floor, provided they are equipped with covers that afford mechanical protection and rigidity equal to or exceeding that of junction box covers.

**EXHIBIT 390.1** Two side-by-side underfloor raceways over 4 in. installed with the required covering in compliance with 390.3(B). (Courtesy of Legrand/Wiremold®)

**(B) Not Permitted.** Underfloor raceways shall not be installed (1) where subject to corrosive vapors or (2) in any hazardous (classified) locations, except as permitted by 504.20 and in Class I, Division 2 locations as permitted in 501.10(B) (3). Unless made of a material judged suitable for the condition or unless corrosion protection approved for the condition is provided, ferrous or nonferrous metal underfloor raceways, junction boxes, and fittings shall not be installed in concrete or in areas subject to severe corrosive influences.

### 390.4 Covering

Raceway coverings shall comply with 390.4(A) through (D).

**(A) Raceways Not over 100 mm (4 in.) Wide.** Half-round and flat-top raceways not over 100 mm (4 in.) in width shall have not less than 20 mm (¾ in.) of concrete or wood above the raceway.

*Exception:* As permitted in 390.4(C) and (D) for flat-top raceways.

**(B) Raceways over 100 mm (4 in.) Wide But Not over 200 mm (8 in.) Wide.** Flat-top raceways over 100 mm (4 in.) but not over 200 mm (8 in.) wide with a minimum of 25 mm (1 in.) spacing between raceways shall be covered with concrete to a depth of not less than 25 mm (1 in.). Raceways spaced less than 25 mm (1 in.) apart shall be covered with concrete to a depth of 38 mm (1½ in.).

**(C) Trench-Type Raceways Flush with Concrete.** Trench-type flush raceways with removable covers shall be permitted to be laid flush with the floor surface. Such approved raceways shall be designed so that the cover plates

provide adequate mechanical protection and rigidity equivalent to junction box covers.

**(D) Other Raceways Flush with Concrete.** In office occupancies, approved metal flat-top raceways, if not over 100 mm (4 in.) in width, shall be permitted to be laid flush with the concrete floor surface, provided they are covered with substantial linoleum that is not less than 1.6 mm ( $\frac{1}{16}$  in.) thick or with equivalent floor covering. Where more than one and not more than three single raceways are each installed flush with the concrete, they shall be contiguous with each other and joined to form a rigid assembly.

### 390.5 Size of Conductors

No conductor larger than that for which the raceway is designed shall be installed in underfloor raceways.

### 390.6 Maximum Number of Conductors in Raceway

The combined cross-sectional area of all conductors or cables shall not exceed 40 percent of the interior cross-sectional area of the raceway.

### 390.7 Splices and Taps

Splices and taps shall be made only in junction boxes.

For the purposes of this section, so-called loop wiring (continuous, unbroken conductor connecting the individual outlets) shall not be considered to be a splice or tap.

*Exception: Splices and taps shall be permitted in trench-type flush raceway having a removable cover that is accessible after installation. The conductors, including splices and taps, shall not fill more than 75 percent of the raceway area at that point.*

When an outlet is removed, the sections of conductors supplying the outlet must be removed from the raceway as well. As is the case with abandoned outlets on loop wiring, reinsulated or spliced conductors are not allowed in raceways, except in trench-type raceways as covered in the exception to 390.7.

### 390.8 Discontinued Outlets

When an outlet is abandoned, discontinued, or removed, the sections of circuit conductors supplying the outlet shall be removed from the raceway. No splices or reinsulated conductors, such as would be the case with abandoned outlets on loop wiring, shall be allowed in raceways.

### 390.9 Laid in Straight Lines

Underfloor raceways shall be laid so that a straight line from the center of one junction box to the center of the next junction

box coincides with the centerline of the raceway system. Raceways shall be firmly held in place to prevent disturbing this alignment during construction.

### 390.10 Markers at Ends

A suitable marker shall be installed at or near each end of each straight run of raceways to locate the last insert.

### 390.11 Dead Ends

Dead ends of raceways shall be closed.

### 390.13 Junction Boxes

Junction boxes shall be leveled to the floor grade and sealed to prevent the free entrance of water or concrete. Junction boxes used with metal raceways shall be metal and shall be electrically continuous with the raceways.

### 390.14 Inserts

Inserts shall be leveled and sealed to prevent the entrance of concrete. Inserts used with metal raceways shall be metal and shall be electrically continuous with the raceway. Inserts set in or on fiber raceways before the floor is laid shall be mechanically secured to the raceway. Inserts set in fiber raceways after the floor is laid shall be screwed into the raceway. When cutting through the raceway wall and setting inserts, chips and other dirt shall not be allowed to remain in the raceway, and tools shall be used that are designed so as to prevent the tool from entering the raceway and damaging conductors that may be in place.

### 390.15 Connections to Cabinets and Wall Outlets

Connections from underfloor raceways to distribution centers and wall outlets shall be made by approved fittings or by any of the wiring methods in Chapter 3, where installed in accordance with the provisions of the respective articles.

### 390.17 Ampacity of Conductors

The ampacity adjustment factors, in 310.15(B)(3), shall apply to conductors installed in underfloor raceways.

## I. General

### 392.1 Scope

This article covers cable tray systems, including ladder, ventilated trough, ventilated channel, solid bottom, and other similar structures.

Cable trays are mechanical support systems. Cable trays are not raceways. See the definition of *raceway* in Article 100.

Cable tray installations are typically an industrial-type wiring method. However, they are sometimes installed in commercial facilities as a wire-and-cable management system for telecommunications/data installations and for feeder and branch-circuit wiring. Exhibit 392.1 is one example of a UL-classified wire mesh-type cable tray used in an accessible underfloor application for MC cable distribution.

**Informational Note:** For further information on cable trays, see ANSI/NEMA-VE 1-2002, *Metal Cable Tray Systems*; NECA/NEMA 105-2007, *Standard for Installing Metal Cable Tray Systems*; and NEMA-FG 1-1998, *Nonmetallic Cable Tray Systems*.

### 392.2 Definition

**Cable Tray System.** A unit or assembly of units or sections and associated fittings forming a structural system used to securely fasten or support cables and raceways.

## II. Installation

### 392.10 Uses Permitted.

Cable tray shall be permitted to be used as a support system for service conductors, feeders, branch circuits, communications circuits, control circuits, and signaling circuits. Cable tray installations shall not be limited to industrial establishments. Where exposed to direct rays of the sun, insulated conductors and jacketed cables shall be identified as being sunlight resistant. Cable trays and their associated fittings shall be identified for the intended use.

**EXHIBIT 392.1** MC cable distribution in a data center installed underfloor application. (Courtesy of CABLOFIL® Legrand)

**(A) Wiring Methods.** The wiring methods in Table 392.10(A) shall be permitted to be installed in cable tray systems under the conditions described in their respective articles and sections.

Section 392.10(A) identifies the raceways and many of the cable types that may be supported in commercial and industrial cable tray installations. Cable tray is rarely used as a major raceway support system. For raceway support systems, the versatility of strut systems exceeds that of cable tray support systems.

Section 392.10(A) does not identify all the specific cable types that may be installed in commercial and industrial cable tray systems. According to Table 392.10(A), other factory-assembled, multiconductor control, signal, and power cables that are specifically approved for installation in cable trays are permitted as well.

**(B) In Industrial Establishments.** The wiring methods in Table 392.10(A) shall be permitted to be used in any industrial establishment under the conditions described in their respective articles. In industrial establishments only, where conditions of maintenance and supervision ensure that only qualified persons service the installed cable tray system, any of the cables in 392.10(B)(1) and (B)(2) shall be permitted

**TABLE 392.10(A) Wiring Methods**

to be installed in ladder, ventilated trough, solid bottom, or ventilated channel cable trays.

Section 392.10(B) permits single-conductor cables (rated 0 to 2000 volts) and Type MV cables to be installed in ladder, ventilated-trough, or ventilated-channel cable trays, provided the installation is located in a qualifying industrial facility.

(1) Single-conductor cables shall be permitted to be installed in accordance with (B)(1)(a) through (B)(1)(c).

(a) Single-conductor cable shall be 1/0 AWG or larger and shall be of a type listed and marked on the surface for use in cable trays. Where 1/0 AWG through 4/0 AWG

single-conductor cables are installed in ladder cable tray, the maximum allowable rung spacing for the ladder cable tray shall be 225 mm (9 in.).

(b) Welding cables shall comply with the provisions of Article 630, Part IV.

(c) Single conductors used as equipment grounding conductors shall be insulated, covered, or bare, and they shall be 4 AWG or larger.

Cable trays used to support welding cables are required by 630.42 to be dedicated for welding cable installation.

(2) Single- and multiconductor medium voltage cables shall be Type MV cable. Single conductors shall be installed in accordance with 392.10(B)(1).

(C) **Hazardous (Classified) Locations.** Cable trays in hazardous (classified) locations shall contain only the cable types and raceways permitted by other articles in this *Code*.

(D) **Nonmetallic Cable Tray.** In addition to the uses permitted elsewhere in 392.10, nonmetallic cable tray shall be permitted in corrosive areas and in areas requiring voltage isolation.

As permitted by 392.10(D), fiberglass cable trays are often used to support cables in corrosive environments or in electrolytic cell rooms where voltage isolation is required. See Article 668, Electrolytic Cells.

### 392.12 Uses Not Permitted.

Cable tray systems shall not be used in hoistways or where subject to severe physical damage.

This section was revised for the 2011 *Code* to delete “other spaces used for environmental air (plenums)” from the uses not permitted. Metal cable trays may be used within these spaces to support only the recognized wiring methods permitted in these spaces. The cable tray types may be ladder, ventilated trough, ventilated channel, or solid bottom. Metal cable trays are not the limiting factor; rather, the cable or wiring method is the limiting factor. In addition, solid side and bottom metal cable tray systems with solid metal covers are permitted in accordance with 392.10(A) and (B).

### 392.18 Cable Tray Installation.

(A) **Complete System.** Cable trays shall be installed as a complete system. Field bends or modifications shall be so made that the electrical continuity of the cable tray system and support for the cables is maintained. Cable tray systems

shall be permitted to have mechanically discontinuous segments between cable tray runs or between cable tray runs and equipment.

Runs of cable tray are not required by 392.18(A) to be totally mechanically continuous from the equipment source to the equipment termination. Breaks in the mechanical continuity of cable tray systems are permitted and often occur at tees, crossovers, elevation changes, or firestops, or for thermal contraction and expansion. Also, cable tray systems are not required to be mechanically connected to the equipment they serve.

**(B) Completed Before Installation.** Each run of cable tray shall be completed before the installation of cables.

**(C) Covers.** In portions of runs where additional protection is required, covers or enclosures providing the required protection shall be of a material that is compatible with the cable tray.

**(D) Through Partitions and Walls.** Cable trays shall be permitted to extend transversely through partitions and walls or vertically through platforms and floors in wet or dry locations where the installations, complete with installed cables, are made in accordance with the requirements of 300.21.

**(E) Exposed and Accessible.** Cable trays shall be exposed and accessible, except as permitted by 392.10(D).

**(F) Adequate Access.** Sufficient space shall be provided and maintained about cable trays to permit adequate access for installing and maintaining the cables.

**(G) Raceways, Cables, Boxes, and Conduit Bodies Supported from Cable Tray Systems.** In industrial facilities where conditions of maintenance and supervision ensure that only qualified persons service the installation and where the cable tray systems are designed and installed to support the load, such systems shall be permitted to support raceways and cables, and boxes and conduit bodies covered in 314.1. For raceways terminating at the tray, a listed cable tray clamp or adapter shall be used to securely fasten the raceway to the cable tray system. Additional supporting and securing of the raceway shall be in accordance with the requirements of the appropriate raceway article. For raceways or cables running parallel to and attached to the bottom or side of a cable tray system, fastening and supporting shall be in accordance with the requirements of the appropriate raceway or cable article.

For boxes and conduit bodies attached to the bottom or side of a cable tray system, fastening and supporting shall be in accordance with the requirements of 314.23.

Section 392.18(G) permits conduit and cable termination supports as well as outlet boxes supported solely by the cable tray in qualifying industrial facilities only. These items are not permitted to be supported solely by the cable tray in commercial installations.

For commercial installations (and nonqualifying industrial facilities), conduits must be supported within 3 ft of the cable tray or within 5 ft if structural members do not permit fastening within 3 ft of the cable tray. Cables connecting to equipment outside the cable tray system must be supported according to their respective article. For example, Type MC cable in the larger sizes is required to be supported outside a cable tray system at intervals not exceeding 6 ft, according to 330.30.

**(H) Marking.** Cable trays containing conductors rated over 600 volts shall have a permanent, legible warning notice carrying the wording “DANGER — HIGH VOLTAGE — KEEP AWAY” placed in a readily visible position on all cable trays, with the spacing of warning notices not to exceed 3 m (10 ft).

This section was added to the 2011 *Code*. Warning requirements currently exist throughout the *NEC* where qualified and unqualified persons may encounter over 600-volt circuits and equipment. Cable tray is permitted to be installed in locations accessible to both qualified and unqualified persons. This requirement is intended to protect persons in those locations.

The requirement is an installation requirement because it is a field marking requirement, rather than a manufacturing specification, because manufacturers may not know how the tray will be used.

## 392.20 Cable and Conductor Installation.

**(A) Multiconductor Cables Rated 600 Volts or Less.** Multiconductor cables rated 600 volts or less shall be permitted to be installed in the same cable tray.

**(B) Cables Rated Over 600 Volts.** Cables rated over 600 volts and those rated 600 volts or less installed in the same cable tray shall comply with either of the following:

- (1) The cables rated over 600 volts are Type MC.
- (2) The cables rated over 600 volts are separated from the cables rated 600 volts or less by a solid fixed barrier of a material compatible with the cable tray.

**(C) Connected in Parallel.** Where single conductor cables comprising each phase, neutral, or grounded conductor of an alternating-current circuit are connected in parallel as permitted in 310.10(H), the conductors shall be installed in

groups consisting of not more than one conductor per phase, neutral, or grounded conductor to prevent current imbalance in the paralleled conductors due to inductive reactance.

Single conductors shall be securely bound in circuit groups to prevent excessive movement due to fault-current magnetic forces unless single conductors are cabled together, such as triplexed assemblies.

The binding or otherwise grouping of 3-phase circuits results in the phase reactances of the conductors being balanced, which reduces the voltage imbalance between the phases of the 3-phase circuit.

**(D) Single Conductors.** Where any of the single conductors installed in ladder or ventilated trough cable trays are 1/0 through 4/0 AWG, all single conductors shall be installed in a single layer. Conductors that are bound together to comprise each circuit group shall be permitted to be installed in other than a single layer.

### 392.22 Number of Conductors or Cables.

**(A) Number of Multiconductor Cables, Rated 2000 Volts or Less, in Cable Trays.** The number of multiconductor cables, rated 2000 volts or less, permitted in a single cable tray shall not exceed the requirements of this section. The conductor sizes apply to both aluminum and copper conductors.

**(1) Ladder or Ventilating Trough Cable Trays Containing Any Mixture of Cables.** Where ladder or ventilated trough cable trays contain multiconductor power or lighting cables, or any mixture of multiconductor power, lighting, control, and signal cables, the maximum number of cables shall conform to the following:

(a) Where all of the cables are 4/0 AWG or larger, the sum of the diameters of all cables shall not exceed the cable tray width, and the cables shall be installed in a single layer. Where the cable ampacity is determined according to 392.80(A)(1)(c), the cable tray width shall not be less than the sum of the diameters of the cables and the sum of the required spacing widths between the cables.

Section 392.22(A)(1) clarifies that cables 1000 kcmil and larger should be installed in a single layer except where these large cables are bundled according to circuit.

(b) Where all of the cables are smaller than 4/0 AWG, the sum of the cross-sectional areas of all cables shall not exceed the maximum allowable cable fill area in Column 1 of Table 392.22(A) for the appropriate cable tray width.

(c) Where 4/0 AWG or larger cables are installed in the same cable tray with cables smaller than 4/0 AWG, the sum of the cross-sectional areas of all cables smaller than 4/0 AWG shall not exceed the maximum allowable fill area resulting from the calculation in Column 2 of Table 392.22(A) for the appropriate cable tray width. The 4/0 AWG and larger cables shall be installed in a single layer, and no other cables shall be placed on them.

#### **(2) Ladder or Ventilating Trough Cable Trays Containing Multiconductor Control and/or Signal Cables Only.**

Where a ladder or ventilated trough cable tray having a usable inside depth of 150 mm (6 in.) or less contains multiconductor control and/or signal cables only, the sum of the cross-sectional areas of all cables at any cross section shall not exceed 50 percent of the interior cross-sectional area of the cable tray. A depth of 150 mm (6 in.) shall be used to calculate the allowable interior cross-sectional area of any cable tray that has a usable inside depth of more than 150 mm (6 in.).

#### **(3) Solid Bottom Cable Trays Containing Any Mixture of Cables.**

Where solid bottom cable trays contain multiconductor power or lighting cables, or any mixture of multiconductor power, lighting, control, and signal cables, the maximum number of cables shall conform to the following:

(a) Where all of the cables are 4/0 AWG or larger, the sum of the diameters of all cables shall not exceed 90 percent of the cable tray width, and the cables shall be installed in a single layer.

(b) Where all of the cables are smaller than 4/0 AWG, the sum of the cross-sectional areas of all cables shall not exceed the maximum allowable cable fill area in Column 3 of Table 392.22(A) for the appropriate cable tray width.

(c) Where 4/0 AWG or larger cables are installed in the same cable tray with cables smaller than 4/0 AWG, the sum of the cross-sectional areas of all cables smaller than 4/0 AWG shall not exceed the maximum allowable fill area resulting from the computation in Column 4 of Table 392.22(A) for the appropriate cable tray width. The 4/0 AWG and larger cables shall be installed in a single layer, and no other cables shall be placed on them.

#### **(4) Solid Bottom Cable Tray Containing Multiconductor Control and/or Signal Cables Only.**

Where a solid bottom cable tray having a usable inside depth of 150 mm (6 in.) or less contains multiconductor control and/or signal cables only, the sum of the cross sectional areas of all cables at any cross section shall not exceed 40 percent of the interior cross-sectional area of the cable tray. A depth of 150 mm (6 in.) shall be used to calculate the allowable interior cross-sectional area of any cable tray that has a usable inside depth of more than 150 mm (6 in.).

**TABLE 392.22(A) Allowable Cable Fill Area for Multiconductor Cables in Ladder, Ventilated Trough, or Solid Bottom Cable Trays for Cables Rated 2000 Volts or Less**

Inside Width of Cable Tray		Maximum Allowable Fill Area for Multiconductor Cables							
		Ladder or Ventilated Trough or Wire Mesh Cable Trays, 392.22(A)(1)				Solid Bottom Cable Trays, 392.22(A)(3)

450	18.0	13,500	21.0	13,500 – (30 Sd)	21 – (1.2 Sd)	10,600	16.5	10,600 – (25 Sd)	16.5 – Sd
500	20.0	15,000	23.5	15,000 – (30 Sd)	23.5 – (1.2 Sd)	11,800	18.5	11,800 – (25 Sd)	18.5 – Sd
600	24.0	18,000	28.0	18,000 – (30 Sd)	28 – (1.2 Sd)	14,200	22.0	14,200 – (25 Sd)	22.0 – Sd
750	30.0	22,500	35.0	22,500 – (30 Sd)	35 – (1.2 Sd)	17,700	27.5	17,700 – (25 Sd)	27.5 – Sd
900	36.0	27,000	42.0	27,000 – (30 Sd)	42 – (1.2 Sd)	21,300	33.0	21,300 – (25 Sd)	33.0 – Sd

<sup>a</sup>The maximum allowable fill areas in Columns 2 and 4 shall be calculated. For example, the maximum allowable fill in mm<sup>2</sup> for a 150-mm wide cable tray in Column 2 shall be 4500 minus (30 multiplied by Sd) [the maximum allowable fill, in square inches, for a 6-in. wide cable tray in Column 2 shall be 7 minus (1.2 multiplied by Sd)].

<sup>b</sup>The term Sd in Columns 2 and 4 is equal to the sum of the diameters, in mm, of all cables 107.2 mm (in inches, of all 4/0 AWG) and larger multiconductor cables in the same cable tray with smaller cables.

**(5) Ventilated Channel Cable Trays Containing Multiconductor Cables of Any Type.** Where ventilated channel cable trays contain multiconductor cables of any type, the following shall apply:

(a) Where only one multiconductor cable is installed, the cross-sectional area shall not exceed the value specified in Column 1 of Table 392.22(A)(5).

(b) Where more than one multiconductor cable is installed, the sum of the cross-sectional area of all cables shall not exceed the value specified in Column 2 of Table 392.22(A)(5).

Section 392.22 contains the requirements for conductor and cable fill in ladder, ventilated trough, ventilated channel, and solid bottom cable trays. Tables 392.22(A)(5), 392.22(A)(6), and 392.22(B)(1) list the maximum fill permitted for various widths. The depth of a channel cable tray (up to 6 in.) is related to fill only where the cable tray contains signal and control cables or where the cable tray contains large cable splices. Heat dissipation is generally not a problem for signal and con-

**TABLE 392.22(A)(5) Allowable Cable Fill Area for Multiconductor Cables in Ventilated Channel Cable Trays for Cables Rated 2000 Volts or Less**

Inside Width of Cable Tray		Maximum Allowable Fill Area for Multiconductor Cables			
		Column 1 One Cable		Column 2 More Than One Cable	
		mm <sup>2</sup>	in. <sup>2</sup>	mm <sup>2</sup>	in. <sup>2</sup>
75	3	1500	2.3	850	1.3
100	4	2900	4.5	1600	2.5
150	6	4500	7.0	2450	3.8

trol cables. Inspectors or contractors, therefore, are not expected to calculate the various combinations of cable tray fill in the field. Installation handbooks for cable tray applications are available from various cable tray manufacturers. Table 392.22(B)(1) was revised for the 2011 *Code* to provide maximum fill requirements for wire mesh cable trays.

**(6) Solid Channel Cable Trays Containing Multiconductor Cables of Any Type.** Where solid channel cable trays contain multiconductor cables of any type, the following shall apply:

(a) Where only one multiconductor cable is installed, the cross-sectional area of the cable shall not exceed the value specified in Column 1 of Table 392.22(A)(6).

(b) Where more than one multiconductor cable is installed, the sum of the cross-sectional area of all cable shall not exceed the value specified in Column 2 of Table 392.22(A)(6).

**TABLE 392.22(A)(6) Allowable Cable Fill Area for Multiconductor Cables in Solid Channel Cable Trays for Cables Rated 2000 Volts or Less**

Inside Width of Cable Tray		Column 1 One Cable		Column 2 More Than One Cable	
mm	in.	mm <sup>2</sup>	in. <sup>2</sup>	mm <sup>2</sup>	in. <sup>2</sup>
50	2	850	1.3	500	0.8
75	3	1300	2.0	700	1.1
100	4	2400	3.7	1400	2.1
150	6	3600	5.5	2100	3.2

**(B) Number of Single-Conductor Cables, Rated 2000 Volts or Less, in Cable Trays.** The number of single conductor cables, rated 2000 volts or less, permitted in a single cable tray section shall not exceed the requirements of this section. The single conductors, or conductor assemblies, shall be evenly distributed across the cable tray. The conductor sizes apply to both aluminum and copper conductors.

**(1) Ladder or Ventilated Trough Cable Trays.** Where ladder or ventilated trough cable trays contain single-conductor cables, the maximum number of single conductors shall conform to the following:

(a) Where all of the cables are 1000 kcmil or larger, the sum of the diameters of all single-conductor cables shall not exceed the cable tray width, and the cables shall be installed in a single layer. Conductors that are bound together to comprise each circuit group shall be permitted to be installed in other than a single layer.

(b) Where all of the cables are from 250 kcmil through 900 kcmil, the sum of the cross-sectional areas of all single-conductor cables shall not exceed the maximum allowable cable fill area in Column 1 of Table 392.22(B)(1) for the appropriate cable tray width.

(c) Where 1000 kcmil or larger single-conductor cables are installed in the same cable tray with single-conductor cables smaller than 1000 kcmil, the sum of the cross sec-

tional areas of all cables smaller than 1000 kcmil shall not exceed the maximum allowable fill area resulting from the computation in Column 2 of Table 392.22(B)(1) for the appropriate cable tray width.

(d) Where any of the single conductor cables are 1/0 through 4/0 AWG, the sum of the diameters of all single conductor cables shall not exceed the cable tray width.

**(2) Ventilated Channel Cable Trays.** Where 50 mm (2 in.), 75 mm (3 in.), 100 mm (4 in.), or 150 mm (6 in.) wide ventilated channel cable trays contain single-conductor cables, the sum of the diameters of all single conductors shall not exceed the inside width of the channel.

**(C) Number of Type MV and Type MC Cables (2001 Volts or Over) in Cable Trays.** The number of cables rated 2001 volts or over permitted in a single cable tray shall not exceed the requirements of this section.

The sum of the diameters of single-conductor and multiconductor cables shall not exceed the cable tray width, and the cables shall be installed in a single layer. Where single conductor cables are triplexed, quadruplexed, or bound together in circuit groups, the sum of the diameters of the single conductors shall not exceed the cable tray width, and these groups shall be installed in single layer arrangement.

### 392.30 Securing and Supporting.

**(A) Cable Trays.** Cable trays shall be supported at intervals in accordance with the installation instructions.

**(B) Cables and Conductors.** Cables and conductors shall be secured to and supported by the cable tray system in accordance with (1), (2) and (3) as applicable:

- (1) In other than horizontal runs, the cables shall be fastened securely to transverse members of the cable runs.
- (2) Supports shall be provided to prevent stress on cables where they enter raceways from cable tray systems.
- (3) The system shall provide for the support of cables and raceway wiring methods in accordance with their corresponding articles. Where cable trays support individual conductors and where the conductors pass from one cable tray to another, or from a cable tray to raceway(s) or from a cable tray to equipment where the conductors are terminated, the distance between the cable trays or between the cable tray and the raceway(s) or the equipment shall not exceed 1.8 m (6 ft). The conductors shall be secured to the cable tray(s) at the transition, and they shall be protected, by guarding or by location, from physical damage.

The 6-ft distance limit applies to mechanically discontinuous cable tray segments for individual conductors but not to

**TABLE 392.22(B)(1) Allowable Cable Fill Area for Single-Conductor Cables in Ladder, Ventilated Trough, or Wire Mesh Cable Trays for Cables Rated 2000 Volts or Less**

Maximum Allowable Fill Area for Single-Conductor Cables in Ladder, Ventilated Trough, or Wire Mesh Cable Trays					
Inside Width of Cable Tray		Column 1 Applicable for 392.22(B)(1)(b) Only		Column 2 <sup>a</sup> Applicable for 392.22(B)(1)(c) Only	
		mm <sup>2</sup>	in. <sup>2</sup>	mm <sup>2</sup>	in. <sup>2</sup>
50	2	1,400	2.0	1,400 – (28 Sd) <sup>b</sup>	2.0 – (1.1 Sd) <sup>b</sup>
100	4	2,800	4.5	2,800 – (28 Sd)	4.5 – (1.1 Sd)
150	6	4,200	6.5	4,200 – (28 Sd) <sup>b</sup>	6.5 – (1.1 Sd) <sup>b</sup>
200	8	5,600	8.5	5,600 – (28 Sd)	8.5 – (1.1 Sd)
225	9	6,100	9.5	6,100 – (28 Sd)	9.5 – (1.1 Sd)
300	12	8,400	13.0	8,400 – (28 Sd)	13.0 – (1.1 Sd)
400	16	11,200	17.5	11,200 – (28 Sd)	17.5 – (1.1 Sd)
450	18	12,600	19.5	12,600 – (28 Sd)	19.5 – (1.1 Sd)
500	20	14,000	21.5	14,000 – (28 Sd)	21.5 – (1.1 Sd)
600	24	16,800	26.0	16,800 – (28 Sd)	26.0 – (1.1 Sd)
750	30	21,000	32.5	21,000 – (28 Sd)	32.5 – (1.1 Sd)
900	36	25,200	39.0	25,200 – (28 Sd)	39.0 – (1.1 Sd)

<sup>a</sup>The maximum allowable fill areas in Column 2 shall be calculated. For example, the maximum allowable fill, in mm<sup>2</sup>, for a 150 mm wide cable tray in Column 2 shall be 4200 minus (28 multiplied by Sd) [the maximum allowable fill, in square inches, for a 6-in. wide cable tray in Column 2 shall be 6.5 minus (1.1 multiplied by Sd)].

<sup>b</sup>The term *Sd* in Column 2 is equal to the sum of the diameters, in mm, of all cables 507 mm<sup>2</sup> (in inches, of all 1000 kcmil) and larger single-conductor cables in the same cable tray with small cables.

trays containing multiconductor cables. For further information regarding multiconductor Type TC tray cable used with discontinuous cable tray, refer to 336.10(6).

### 392.46 Bushed Conduit and Tubing.

A box shall not be required where cables or conductors are installed in bushed conduit and tubing used for support or for protection against physical damage.

### 392.56 Cable Splices.

Cable splices made and insulated by approved methods shall be permitted to be located within a cable tray, provided they are accessible. Splices shall be permitted to project above the side rails where not subject to physical damage.

Section 392.56 permits splices to extend above the side rail of cable tray, provided they are not subject to physical damage.

### 392.60 Grounding and Bonding.

**(A) Metallic Cable Trays.** Metallic cable trays shall be permitted to be used as equipment grounding conductors where continuous maintenance and supervision ensure that qualified persons service the installed cable tray system and

the cable tray complies with provisions of this section. Metallic cable trays that support electrical conductors shall be grounded as required for conductor enclosures in accordance with 250.96 and Part IV of Article 250. Metal cable trays containing only non-power conductors shall be electrically continuous through approved connections or the use of a bonding jumper not smaller than a 10 AWG.

**Informational Note:** Examples of non-power conductors include nonconductive optical fiber cables and Class 2 and Class 3 Remote Control Signaling and Power Limiting Circuits.

Section 392.60(A) permits the use of the cable tray as the equipment grounding conductor in certain installations. To qualify as an equipment grounding conductor, the cable tray system must meet all four requirements of 392.60(B).

Section 392.60(A), together with 250.96, requires all cable tray systems that support electrical conductors (whether mechanically continuous or with isolated segments) to be electrically continuous and effectively bonded and grounded. This requirement applies whether or not the cable tray is used as an equipment grounding conductor or is used for service conductors and connected to the grounded system conductor (or the grounding electrode conductor for ungrounded systems). Where a metal cable tray contains only non-power conductors, such as fire alarm, communications,

**TABLE 392.60(A) Metal Area Requirements for Cable Trays Used as Equipment Grounding Conductor**

Maximum Fuse Ampere Rating, Circuit Breaker Ampere Trip Setting, or Circuit Breaker Protective Relay Ampere Trip Setting for Ground-Fault Protection of Any Cable Circuit in the Cable Tray System	Minimum Cross-Sectional Area of Metal <sup>a</sup>			
	Steel Cable Trays		Aluminum Cable Trays	
	mm <sup>2</sup>	in. <sup>2</sup>	mm <sup>2</sup>	in. <sup>2</sup>
60	129	0.20	129	0.20
100	258	0.40	129	0.20
200	451.5	0.70	129	0.20
400	645	1.00	258	0.40
600	967.5	1.50 <sup>b</sup>	258	0.40
1000	—	—	387	0.60
1200	—	—	645	1.00
1600	—	—	967.5	1.50
2000	—	—	1290	2.00 <sup>b</sup>

<sup>a</sup>Total cross-sectional area of both side rails for ladder or trough cable trays; or the minimum cross-sectional area of metal in channel cable trays or cable trays of one-piece construction.

<sup>b</sup>Steel cable trays shall not be used as equipment grounding conductors for circuits with ground-fault protection above 600 amperes. Aluminum cable trays shall not be used as equipment grounding conductors for circuits with ground-fault protection above 2000 amperes.

CATV, or broadband conductors, the tray must be maintained electrically continuous through the use of approved connection or the use of a bonding jumper that is not smaller than a 10 AWG. Where a bonding jumper is used, it is permitted to be stranded or solid.

**(B) Steel or Aluminum Cable Tray Systems.** Steel or aluminum cable tray systems shall be permitted to be used as equipment grounding conductors, provided all the following requirements are met:

- (1) The cable tray sections and fittings are identified as an equipment grounding conductor.
- (2) The minimum cross-sectional area of cable trays conform to the requirements in Table 392.60(A).
- (3) All cable tray sections and fittings are legibly and durably marked to show the cross-sectional area of metal in channel cable trays, or cable trays of one-piece construction, and the total cross-sectional area of both side rails for ladder or trough cable trays.
- (4) Cable tray sections, fittings, and connected raceways are bonded in accordance with 250.96, using bolted mechanical connectors or bonding jumpers sized and installed in accordance with 250.102.

For cable tray systems in commercial occupancies, designers are afforded the option to specify multiconductor cables without equipment grounding conductors (EGCs) and to use the cable tray system as the required EGC, provided the cable tray system meets the requirements of 392.60(A) and (B). Exhibit 392.2 illustrates an example of the grounding and bonding of multiconductor cables in cable trays with conduit runs to power equipment.

For cable tray systems in industrial establishments that qualify, the designer is also afforded the option to specify single-conductor cables without a cable EGC and to use the cable tray as the required EGC. Again, this option is available only if the cable tray system meets the requirements of 392.60(A) and (B).

**(C) Transitions.** Where metallic cable tray systems are mechanically discontinuous, as permitted in 392.18(A), a bonding jumper sized in accordance with 250.102 shall connect the two sections of the cable tray, or the cable tray and the raceway or equipment. Bonding shall be in accordance with 250.96.

Most important, especially for discontinuous cable tray segments, is the bonding of the entire cable tray system. According to 250.96(A), properly sized and installed bonding conductors must be installed across any mechanical discontinuities in the cable tray system and across any space between the cable tray and the conductor termination equipment enclosure or its equipment ground bus.

Cables installed within cable tray systems must meet or exceed the support requirements of the applicable article that covers the cables. This requirement either limits the gap distance in cable tray runs and between the cable tray and the equipment enclosures or requires intermediate cable supports at the appropriate distances in place of the cable tray.

## 392.80 Ampacity of Conductors.

**(A) Ampacity of Cables, Rated 2000 Volts or Less, in Cable Trays.**

**(1) Multiconductor Cables.** The allowable ampacity of multiconductor cables, nominally rated 2000 volts or less, installed according to the requirements of 392.22(A) shall be as given in Table 310.15(B)(16) and Table 310.15(B)(18), subject to the provisions of (A)(1)(a), (b), (c), and 310.15(A)(2).

(a) The adjustment factors of 310.15(B)(3)(a) shall apply only to multiconductor cables with more than three current-carrying conductors. Adjustment factors shall be limited to the number of current-carrying conductors in the cable and not to the number of conductors in the cable tray.

**EXHIBIT 392.2** An example of multiconductor cables in cable trays with conduit runs to power equipment where bonding is provided in accordance with 392.60(B)(4).

(b) Where cable trays are continuously covered for more than 1.8 m (6 ft) with solid unventilated covers, not over 95 percent of the allowable ampacities of Table 310.15(B)(16) and Table 310.15(B)(18) shall be permitted for multiconductor cables.

(c) Where multiconductor cables are installed in a single layer in uncovered trays, with a maintained spacing of not less than one cable diameter between cables, the ampacity shall not exceed the allowable ambient temperature-corrected ampacities of multiconductor cables, with not more than three insulated conductors rated 0 through 2000 volts in free air, in accordance with 310.15(C).

Informational Note: See Table B.310.15(B)(2)(3).

Exhibit 392.3 illustrates the requirements of 392.80(A)(1)(c). Note that the cables, rated 2000 volts or less, are installed in a single layer in an uncovered tray, with not less than one cable diameter between cables and not more than three conductors per cable. Refer to Table B.310.15(B)(2)(3) in Informative Annex B for the ampacity of the conductors in this configuration.

**(2) Single-Conductor Cables.** The allowable ampacity of single-conductor cables shall be as permitted by 310.15(A)(2).

**EXHIBIT 392.3** Illustration of 392.80(A)(1)(c) for multiconductor cables, 2000 volts or less, with not more than three conductors per cable [ampacity to be determined from Table B.310.15(B)(2)(3) in Informative Annex B].

The adjustment factors of 310.15(B)(3)(a) shall not apply to the ampacity of cables in cable trays. The ampacity of single-conductor cables, or single conductors cabled together (triplexed, quadruplexed, etc.), nominally rated 2000 volts or less, shall comply with the following:

(a) Where installed according to the requirements of 392.22(B), the ampacities for 600 kcmil and larger single-conductor cables in uncovered cable trays shall not exceed 75 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19). Where cable trays are continuously covered for more than 1.8 m (6 ft) with solid unventilated covers, the ampacities for 600 kcmil and larger cables shall not exceed 70 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19).

(b) Where installed according to the requirements of 392.22(B), the ampacities for 1/0 AWG through 500 kcmil single-conductor cables in uncovered cable trays shall not exceed 65 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19). Where cable trays are continuously covered for more than 1.8 m (6 ft) with solid unventilated covers, the ampacities for 1/0 AWG through 500 kcmil cables shall not exceed 60 percent of the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19).

(c) Where single conductors are installed in a single layer in uncovered cable trays, with a maintained space of not less than one cable diameter between individual conductors, the ampacity of 1/0 AWG and larger cables shall not exceed the allowable ampacities in Table 310.15(B)(17) and Table 310.15(B)(19).

*Exception to (2)(3)(c): For solid bottom cable trays the ampacity of single conductor cables shall be determined by 310.15(C).*

(d) Where single conductors are installed in a triangular or square configuration in uncovered cable trays, with a maintained free airspace of not less than 2.15 times one conductor diameter ( $2.15 \times \text{O.D.}$ ) of the largest conductor con-

tained within the configuration and adjacent conductor configurations or cables, the ampacity of 1/0 AWG and larger cables shall not exceed the allowable ampacities of two or three single insulated conductors rated 0 through 2000 volts supported on a messenger in accordance with 310.15(B).

Informational Note: See Table 310.15(B)(20).

Section 392.80(A)(2)(d) recognizes single conductors in a triangular configuration installed in a cable tray with maintained spacing as having the same ampacity as three single insulated conductors on a messenger. The maintained spacing allows air to circulate around the cable.

Where three single conductors, nominally rated 2000 volts or less, are cabled together in a triangular configuration, with not less than 2.15 times the conductor diameter ( $2.15 \times \text{OD}$ ) between groups, as illustrated in Exhibit 392.4, the ampacity of the conductors is determined in accordance with Table 310.15(B)(20).

**EXHIBIT 392.4** Illustration of 392.80(A)(2), for three single conductors installed in a triangular configuration with spacing between groups of not less than 2.15 times the conductor diameter [ampacities to be determined from Table 310.15(B)(20)].

Where single conductors are installed in cable trays, their ampacities are permitted to be calculated using many variations of Tables 310.15(B)(16), 310.15(B)(17), and 310.15(B)(19). Where these single-conductor cables emerge from a cable tray installation and are terminated at circuit breakers, distribution switchgear, and similar electrical equipment, the temperature limitations of the electrical equipment terminals should be coordinated with the ampacity of the single-conductor cables. As stated in both the *UL Guide Information for Electrical Equipment Directory — The White Book-2010* and in 110.14(C)(1), unless the equipment is listed and marked otherwise, conductor ampacities used in determining equipment terminations must be based on Table 310.15(B)(16) as modified by 310.15(B)(1) through (B)(7).

**(3) Combinations of Multiconductor and Single-Conductor Cables.** Where a cable tray contains a combination of multiconductor and single-conductor cables, the allowable ampacities shall be as given in 392.80(A)(1) for multiconductor cables and 392.80(A)(2) for single-conductor cables, provided that the following conditions apply:

- (1) The sum of the multiconductor cable fill area as a percentage of the allowable fill area for the tray calculated in accordance with 392.22(A), and the single-conductor cable fill area as a percentage of the allowable fill area for the tray calculated in accordance with 392.22(B), totals not more than 100 percent.
- (2) Multiconductor cables are installed according to 392.22(A) and single-conductor cables are installed according to 392.22(B) and 392.22(C) and (D).

Section 392.80(A)(3) clarifies that multiconductor and single-conductor cable installed in the same tray must not exceed the fill requirements for each type of cable as if it were installed in its own tray and all installation requirements and ampacity limits for each cable type apply.

**(B) Ampacity of Type MV and Type MC Cables (2001 Volts or Over) in Cable Trays.** The ampacity of cables, rated 2001 volts, nominal, or over, installed according to 392.22(C) shall not exceed the requirements of this section.

**(1) Multiconductor Cables (2001 Volts or Over).** The allowable ampacity of multiconductor cables shall be as given in Table 310.60(C)(75) and Table 310.60(C)(76), subject to the following provisions:

(a) Where cable trays are continuously covered for more than 1.8 m (6 ft) with solid unventilated covers, not more than 95 percent of the allowable ampacities of Table 310.60(C)(75) and Table 310.60(C)(76) shall be permitted for multiconductor cables.

(b) Where multiconductor cables are installed in a single layer in uncovered cable trays, with maintained spacing of not less than one cable diameter between cables, the ampacity shall not exceed the allowable ampacities of Table 310.60(C)(71) and Table 310.60(C)(72).

**(2) Single-Conductor Cables (2001 Volts or Over).** The ampacity of single-conductor cables, or single conductors cabled together (triplexed, quadruplexed, etc.), shall comply with the following:

(a) The ampacities for 1/0 AWG and larger single-conductor cables in uncovered cable trays shall not exceed 75 percent of the allowable ampacities in Table 310.60(C)(69) and Table 310.60(C)(70). Where the cable trays are covered for more than 1.8 m (6 ft) with solid unventilated covers, the

ampacities for 1/0 AWG and larger single-conductor cables shall not exceed 70 percent of the allowable ampacities in Table 310.60(C)(69) and Table 310.60(C)(70).

(b) Where single-conductor cables are installed in a single layer in uncovered cable trays, with a maintained space of not less than one cable diameter between individual conductors, the ampacity of 1/0 AWG and larger cables shall not exceed the allowable ampacities in Table 310.60(C)(69) and Table 310.60(C)(70).

(c) Where single conductors are installed in a triangular or square configuration in uncovered cable trays, with a maintained free air space of not less than 2.15 times the diameter ( $2.15 \times \text{O.D.}$ ) of the largest conductor contained within the configuration and adjacent conductor configurations or cables, the ampacity of 1/0 AWG and larger cables shall not exceed the allowable ampacities in Table 310.60(C)(67) and Table 310.60(C)(68).

### III. Construction Specifications

#### 392.100 Construction.

**(A) Strength and Rigidity.** Cable trays shall have suitable strength and rigidity to provide adequate support for all contained wiring.

**(B) Smooth Edges.** Cable trays shall not have sharp edges, burrs, or projections that could damage the insulation or jackets of the wiring.

**(C) Corrosion Protection.** Cable tray systems shall be corrosion resistant. If made of ferrous material, the system shall be protected from corrosion as required by 300.6.

**(D) Side Rails.** Cable trays shall have side rails or equivalent structural members.

**(E) Fittings.** Cable trays shall include fittings or other suitable means for changes in direction and elevation of runs.

**(F) Nonmetallic Cable Tray.** Nonmetallic cable trays shall be made of flame-retardant material.

## I. General

### 394.1 Scope

This article covers the use, installation, and construction specifications of concealed knob-and-tube wiring.

### 394.2. Definition

**Concealed Knob-and-Tube Wiring.** A wiring method using knobs, tubes, and flexible nonmetallic tubing for the protection and support of single insulated conductors.

Knob-and-tube wiring is allowed to be concealed, whereas open wiring on insulators (Article 398) is required to be exposed. Concealed knob-and-tube wiring is designed for use in hollow spaces of walls, ceilings, and attics and utilizes the free air in such spaces for heat dissipation. Conductors used for knob-and-tube work may be of any general-use type specified by Article 310.

## II. Installation

### 394.10 Uses Permitted

Concealed knob-and-tube wiring shall be permitted to be installed in the hollow spaces of walls and ceilings, or in unfinished attics and roof spaces as provided by 394.23, only as follows:

- (1) For extensions of existing installations
- (2) Elsewhere by special permission

Concealed knob-and-tube wiring is permitted to be installed only for extensions of existing installations or where

special permission is granted by the authority having jurisdiction of enforcement of the *Code*. See definition of *special permission* in Article 100.

### 394.12 Uses Not Permitted

Concealed knob-and-tube wiring shall not be used in the following:

- (1) Commercial garages
- (2) Theaters and similar locations
- (3) Motion picture studios
- (4) Hazardous (classified) locations
- (5) Hollow spaces of walls, ceilings, and attics where such spaces are insulated by loose, rolled, or foamed-in-place insulating material that envelops the conductors

Blown-in, foamed-in, or rolled insulation prevents the dissipation of heat into the free air space, resulting in higher conductor temperature, which could cause insulation breakdown and possible ignition of the insulation. Section 394.12 prohibits installation of knob-and-tube wiring in hollow spaces that have been weatherized.

### 394.17 Through or Parallel to Framing Members

Conductors shall comply with 398.17 where passing through holes in structural members. Where passing through wood cross members in plastered partitions, conductors shall be protected by noncombustible, nonabsorbent, insulating tubes extending not less than 75 mm (3 in.) beyond the wood member.

The requirement for insulated tubes where knob-and-tube wiring passes through wood cross members in plastered partitions is intended to protect the wire from contact with plaster that is likely to accumulate on horizontal wood members.

The “running board” method of protecting open-type conductors where they are installed at a height of 7 ft or less above the floor or floor joists in an accessible attic is illustrated in Exhibit 394.1. This method is applied in attics that are accessible by stairways or permanent ladders and where such spaces are generally used for storage.

### 394.19 Clearances

**(A) General.** A clearance of not less than 75 mm (3 in.) shall be maintained between conductors and a clearance of not less than 25 mm (1 in.) between the conductor and the surface over which it passes.

**EXHIBIT 394.1** Open wiring in an accessible attic protected by running boards, as required by 394.23(A).

**(B) Limited Conductor Space.** Where space is too limited to provide these minimum clearances, such as at meters, panelboards, outlets, and switch points, the individual conductors shall be enclosed in flexible nonmetallic tubing, which shall be continuous in length between the last support and the enclosure or terminal point.

**(C) Clearance from Piping, Exposed Conductors, and So Forth.** Conductors shall comply with 398.19 for clearances from other exposed conductors, piping, and so forth.

### 394.23 In Accessible Attics

Conductors in unfinished attics and roof spaces shall comply with 394.23(A) or (B).

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

**(A) Accessible by Stairway or Permanent Ladder.** Conductors shall be installed along the side of or through bored holes in floor joists, studs, or rafters. Where run through bored holes, conductors in the joists and in studs or rafters to a height of not less than 2.1 m (7 ft) above the floor or floor joists shall be protected by substantial running boards extending not less than 25 mm (1 in.) on each side of the conductors. Running boards shall be securely fastened in place. Running boards and guard strips shall not be required where conductors are installed along the sides of joists, studs, or rafters.

**(B) Not Accessible by Stairway or Permanent Ladder.** Conductors shall be installed along the sides of or through bored holes in floor joists, studs, or rafters.

*Exception: In buildings completed before the wiring is installed, attic and roof spaces that are not accessible by stairway or permanent ladder and have headroom at all points less than 900 mm (3 ft), the wiring shall be permitted to be installed on the edges of rafters or joists facing the attic or roof space.*

### 394.30 Securing and Supporting

**(A) Supporting.** Conductors shall be rigidly supported on noncombustible, nonabsorbent insulating materials and shall not contact any other objects. Supports shall be installed as follows:

- (1) Within 150 mm (6 in.) of each side of each tap or splice, and
- (2) At intervals not exceeding 1.4 m (4½ ft).

Where it is impracticable to provide supports, conductors shall be permitted to be fished through hollow spaces in dry locations, provided each conductor is individually enclosed in flexible nonmetallic tubing that is in continuous lengths between supports, between boxes, or between a support and a box.

**(B) Securing.** Where solid knobs are used, conductors shall be securely tied thereto by tie wires having insulation equivalent to that of the conductor.

### 394.42 Devices

Switches shall comply with 404.4 and 404.10(B).

### 394.56 Splices and Taps

Splices shall be soldered unless approved splicing devices are used. In-line or strain splices shall not be used.

## III. Construction Specifications

### 394.104 Conductors

Conductors shall be of a type specified by Article 310.

  - (B) Neutral Conductor
  - (C) Equipment Grounding Conductor
- 396.56 Conductor Splices and Taps
- 396.60 Grounding

I. General

396.1 Scope

This article covers the use, installation, and construction specifications for messenger-supported wiring.

Messenger-supported wiring systems have been manufactured and successfully used in industrial installations for many years. They have also been used for many years as service drops by utilities for commercial and residential installations. See references to messenger-supported wiring in 225.6(A)(1) and (B).

396.2 Definition

**Messenger-Supported Wiring.** An exposed wiring support system using a messenger wire to support insulated conductors by any one of the following:

- (1) A messenger with rings and saddles for conductor support
- (2) A messenger with a field-installed lashing material for conductor support
- (3) Factory-assembled aerial cable
- (4) Multiplex cables utilizing a bare conductor, factory assembled and twisted with one or more insulated conductors, such as duplex, triplex, or quadruplex type of construction

II. Installation

396.10 Uses Permitted

**(A) Cable Types.** The cable types in Table 396.10(A) shall be permitted to be installed in messenger-supported wiring under the conditions described in the article or section referenced for each.

**(B) In Industrial Establishments.** In industrial establishments only, where conditions of maintenance and supervision ensure that only qualified persons service the installed

TABLE 396.10(A) Cable Types

Cable Type	Section	Article
Medium-voltage cable		328
Metal-clad cable		330
Mineral-insulated, metal-sheathed cable		332
Multiconductor service-entrance cable		338
Multiconductor underground feeder and branch-circuit cable		340
Other factory-assembled, multiconductor control, signal, or power cables that are identified for the use		
Power and control tray cable		336
Power-limited tray cable	725.154(C) and 725.179(E)	

messenger-supported wiring, the following shall be permitted:

- (1) Any of the conductor types shown in Table 310.104(A) or Table 310.104(B)
- (2) MV cable

Where exposed to weather, conductors shall be listed for use in wet locations. Where exposed to direct rays of the sun, conductors or cables shall be sunlight resistant.

Some of the triplex and quadruplex cable used by utilities as service-drop cable does not use conductors recognized in Table 310.104(A) and does not meet the requirements of Article 310. Such triplex and quadruplex cable would be acceptable only where approved by the authority having jurisdiction.

See 310.15(B) and Table 310.15(B)(20) for two or three single-insulated conductors supported on a messenger. See 310.15(C) and Informative Annex B, Table B.310.15(B)(20) (3), for ampacities of conductors for other cable types.

**(C) Hazardous (Classified) Locations.** Messenger-supported wiring shall be permitted to be used in hazardous (classified) locations where the contained cables and messenger-supported wiring are specifically permitted by other articles in this Code.

396.12 Uses Not Permitted

Messenger-supported wiring shall not be used in hoistways or where subject to physical damage.

396.30 Messenger

**(A) Support.** The messenger shall be supported at dead ends and at intermediate locations so as to eliminate tension

on the conductors. The conductors shall not be permitted to come into contact with the messenger supports or any structural members, walls, or pipes.

**(B) Neutral Conductor.** Where the messenger is used as a neutral conductor, it shall comply with the requirements of 225.4, 250.184(A), 250.184(B)(7), and 250.186(B).

**(C) Equipment Grounding Conductor.** Where the messenger is used as an equipment grounding conductor, it shall comply with the requirements of 250.32(B), 250.118, 250.184(B)(8), and 250.186(D).

### 396.56 Conductor Splices and Taps

Conductor splices and taps made and insulated by approved methods shall be permitted in messenger-supported wiring.

### 396.60 Grounding

The messenger shall be grounded as required by 250.80 and 250.86 for enclosure grounding.

## I. General

### 398.1 Scope

This article covers the use, installation, and construction specifications of open wiring on insulators.

### 398.2 Definition

**Open Wiring on Insulators.** An exposed wiring method using cleats, knobs, tubes, and flexible tubing for the protection and support of single insulated conductors run in or on buildings.

Open wiring on insulators is an exposed wiring method that is not permitted to be concealed by the structure or finish of the building. It is permitted indoors or outdoors, in dry or wet locations, and where subject to corrosive vapors, provided the insulation choice from Table 310.104 is suitable for use in a corrosive environment.

This wiring method is not permitted for temporary lighting and power circuits on construction sites but is permitted for lighting and power circuits in agricultural buildings [see 547.5(A)]. It may also be used for services (see 230.43).

## II. Installation

### 398.10 Uses Permitted

Open wiring on insulators shall be permitted only for industrial or agricultural establishments on systems of 600 volts, nominal, or less, as follows:

- (1) Indoors or outdoors
- (2) In wet or dry locations
- (3) Where subject to corrosive vapors
- (4) For services

See Tables 310.15(B)(17) and 310.15(B)(19) for ampacities of conductors.

### 398.12 Uses Not Permitted

Open wiring on insulators shall not be installed where concealed by the building structure.

### 398.15 Exposed Work

**(A) Dry Locations.** In dry locations, where not exposed to physical damage, conductors shall be permitted to be separately enclosed in flexible nonmetallic tubing. The tubing shall be in continuous lengths not exceeding 4.5 m (15 ft) and secured to the surface by straps at intervals not exceeding 1.4 m (4½ ft).

**(B) Entering Spaces Subject to Dampness, Wetness, or Corrosive Vapors.** Conductors entering or leaving locations

subject to dampness, wetness, or corrosive vapors shall have drip loops formed on them and shall then pass upward and inward from the outside of the buildings, or from the damp, wet, or corrosive location, through noncombustible, nonabsorbent insulating tubes.

Informational Note: See 230.52 for individual conductors entering buildings or other structures.

**(C) Exposed to Physical Damage.** Conductors within 2.1 m (7 ft) from the floor shall be considered exposed to physical damage. Where open conductors cross ceiling joists and wall studs and are exposed to physical damage, they shall be protected by one of the following methods:

- (1) Guard strips not less than 25 mm (1 in.) nominal in thickness and at least as high as the insulating supports, placed on each side of and close to the wiring.
- (2) A substantial running board at least 13 mm (½ in.) thick in back of the conductors with side protections. Running boards shall extend at least 25 mm (1 in.) outside the conductors, but not more than 50 mm (2 in.), and the protecting sides shall be at least 50 mm (2 in.) high and at least 25 mm (1 in.), nominal, in thickness.
- (3) Boxing made in accordance with 398.15(C)(1) or (C)(2) and furnished with a cover kept at least 25 mm (1 in.) away from the conductors within. Where protecting vertical conductors on side walls, the boxing shall be closed at the top and the holes through which the conductors pass shall be bushed.
- (4) Rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or electrical metallic tubing. When installed in metal piping, the conductors shall be encased in continuous lengths of approved flexible tubing.

### 398.17 Through or Parallel to Framing Members

Open conductors shall be separated from contact with walls, floors, wood cross members, or partitions through which they pass by tubes or bushings of noncombustible, nonabsorbent insulating material. Where the bushing is shorter than the hole, a waterproof sleeve of noninductive material shall be inserted in the hole and an insulating bushing slipped into the sleeve at each end in such a manner as to keep the conductors absolutely out of contact with the sleeve. Each conductor shall be carried through a separate tube or sleeve.

Informational Note: See 310.15(A)(3) for temperature limitation of conductors.

### 398.19 Clearances

Open conductors shall be separated at least 50 mm (2 in.) from metal raceways, piping, or other conducting material, and from any exposed lighting, power, or signaling conduc-

tor, or shall be separated therefrom by a continuous and firmly fixed nonconductor in addition to the insulation of the conductor. Where any insulating tube is used, it shall be secured at the ends. Where practicable, conductors shall pass over rather than under any piping subject to leakage or accumulations of moisture.

The requirement for additional protective insulation on open wiring is to prevent contact with metal piping, metal objects, or exposed conductors of other circuits.

### 398.23 In Accessible Attics

Conductors in unfinished attics and roof spaces shall comply with 398.23(A) or (B).

**(A) Accessible by Stairway or Permanent Ladder.** Conductors shall be installed along the side of or through bored holes in floor joists, studs, or rafters. Where run through bored holes, conductors in the joists and in studs or rafters to a height of not less than 2.1 m (7 ft) above the floor or floor joists shall be protected by substantial running boards extending not less than 25 mm (1 in.) on each side of the conductors. Running boards shall be securely fastened in place. Running boards and guard strips shall not be required for conductors installed along the sides of joists, studs, or rafters.

**(B) Not Accessible by Stairway or Permanent Ladder.** Conductors shall be installed along the sides of or through bored holes in floor joists, studs, or rafters.

*Exception: In buildings completed before the wiring is installed, in attic and roof spaces that are not accessible by stairway or permanent ladder and have headroom at all points less than 900 mm (3 ft), the wiring shall be permitted to be installed on the edges of rafters or joists facing the attic or roof space.*

### 398.30 Securing and Supporting

**(A) Conductor Sizes Smaller Than 8 AWG.** Conductors smaller than 8 AWG shall be rigidly supported on noncombustible, nonabsorbent insulating materials and shall not contact any other objects. Supports shall be installed as follows:

- (1) Within 150 mm (6 in.) from a tap or splice
- (2) Within 300 mm (12 in.) of a dead-end connection to a lampholder or receptacle
- (3) At intervals not exceeding 1.4 m (4½ ft) and at closer intervals sufficient to provide adequate support where likely to be disturbed

**(B) Conductor Sizes 8 AWG and Larger.** Supports for conductors 8 AWG or larger installed across open spaces shall be permitted up to 4.5 m (15 ft) apart if noncombustible, nonab-

sorbent insulating spacers are used at least every 1.4 m (4½ ft) to maintain at least 65 mm (2½ in.) between conductors.

Where not likely to be disturbed in buildings of mill construction, 8 AWG and larger conductors shall be permitted to be run across open spaces if supported from each wood cross member on approved insulators maintaining 150 mm (6 in.) between conductors.

Mill construction is generally considered to be a building in which the floors and ceilings are supported by wood timbers or beams or wood cross members spaced approximately 15 ft apart. This type of construction is sometimes referred to as plank-on-timber construction. Section 398.30(B) permits 8 AWG and larger conductors to span the 15-ft distance where the ceilings are high and free of obstructions and the conductors are unlikely to come into contact with other objects.

**(C) Industrial Establishments.** In industrial establishments only, where conditions of maintenance and supervision ensure that only qualified persons service the system, conductors of sizes 250 kcmil and larger shall be permitted to be run across open spaces where supported at intervals up to 9.0 m (30 ft) apart.

One practice commonly found in industrial buildings is to install open feeders on insulators, which are mounted on the bottom of roof trusses at every bay location. Many bays are more than 15 ft wide. Therefore, 398.30(C) permits size 250 kcmil and larger conductors to be supported at 30-ft intervals in industrial buildings where it is ensured that qualified persons will service the system.

In addition to the ease and economy of installation or alteration of open wiring, the close spacing of conductors reduces the reactance of a circuit and, hence, reduces the voltage drop.

**(D) Mounting of Conductor Supports.** Where nails are used to mount knobs, they shall not be smaller than ten-penny. Where screws are used to mount knobs, or where nails or screws are used to mount cleats, they shall be of a length sufficient to penetrate the wood to a depth equal to at least one-half the height of the knob and the full thickness of the cleat. Cushion washers shall be used with nails.

**(E) Tie Wires.** Conductors 8 AWG or larger and supported on solid knobs shall be securely tied thereto by tie wires having an insulation equivalent to that of the conductor.

### 398.42 Devices

Surface-type snap switches shall be mounted in accordance with 404.10(A), and boxes shall not be required. Other type switches shall be installed in accordance with 404.4.

## III. Construction Specifications

### 398.104 Conductors

Conductors shall be of a type specified by Article 310.

## ARTICLE 399 Outdoor Overhead Conductors over 600 Volts

### Contents

  - (A) Conductors
  - (B) Structures
  - (C) Insulators

### 399.1 Scope

This article covers the use and installation for outdoor overhead conductors over 600 volts, nominal.

This article is new in the 2011 *Code*. Premises wiring installations, utilizing over 600-volt systems, currently exist in numerous locations and have become more common as electrical usage has increased. Many of those installations utilize overhead bare conductors on insulators as feeders and branch circuits to safely distribute power to multiple buildings, structures, and equipment locations. This article recognizes this wiring method and provides requirements for these installations.

### 399.2 Definition

**Outdoor Overhead Conductors.** Single conductors, insulated, covered, or bare, installed outdoors on support structures.

### 399.10 Uses Permitted

Outdoor overhead conductors over 600 volts, nominal, shall be permitted only for systems rated over 600 volts, nominal, as follows:

- (1) Outdoors
- (2) For service conductors, feeders, or branch circuits

Informational Note: For additional information on outdoor overhead conductors over 600 volts, see ANSI/IEEE C2-2007, *National Electrical Safety Code*.

**399.12 Uses Not Permitted**

Overhead conductors, over 600 volts, nominal shall not be permitted to be installed indoors.

**399.30 Support**

**(A) Conductors.** Documentation of the engineered design by a licensed professional engineer engaged primarily in the design of such systems for the spacing between conductors shall be available upon request of the authority having jurisdiction and shall include consideration of the following:

- (1) Applied voltage
- (2) Conductor size
- (3) Distance between support structures
- (4) Type of structure
- (5) Wind/ice loading
- (6) Surge protection

**(B) Structures.** Structures of wood, metal, concrete, or combinations of those materials, shall be provided for support of overhead conductors over 600 volts, nominal. Documentation of the engineered design by a licensed professional engineer engaged primarily in the design of such systems and the installation of each support structure shall

be available upon request of the authority having jurisdiction and shall include consideration of the following:

- (1) Soil conditions
- (2) Foundations and structure settings
- (3) Weight of all supported conductors and equipment
- (4) Weather loading and other conditions such as but not limited to ice, wind, temperature, and lightning
- (5) Angle where change of direction occurs
- (6) Spans between adjacent structures
- (7) Effect of dead-end structures
- (8) Strength of guys and guy anchors
- (9) Structure size and material(s)
- (10) Hardware

**(C) Insulators.** Insulators used to support conductors shall be rated for all of the following:

- (1) Applied phase-to-phase voltage
- (2) Mechanical strength required for each individual installation
- (3) Impulse withstand BIL in accordance with Table 490.24

Informational Note: 399.30(A), (B), and (C) are not all-inclusive lists.

### I. General

#### 400.1 Scope

This article covers general requirements, applications, and construction specifications for flexible cords and flexible cables.

Flexible cords and cables, because of the nature of their use, are not considered to be wiring methods. Wiring methods are covered in Chapter 3 of the *Code*. Careful study of 400.7, Uses Permitted, and 400.8, Uses Not Permitted, is required before choosing flexible cords or cables for a specific application. The flexible cords and cables referred to in Article 400 are not limited to use with portable equipment.

#### 400.2 Other Articles

Flexible cords and flexible cables shall comply with this article and with the applicable provisions of other articles of this *Code*.

#### 400.3 Suitability

Flexible cords and cables and their associated fittings shall be suitable for the conditions of use and location.

#### 400.4 Types

Flexible cords and flexible cables shall conform to the description in Table 400.4. Types of flexible cords and flexible cables other than those listed in the table shall be the subject of special investigation.

TABLE 400.4 Flexible Cords and Cables (See 400.4.)

Notes:

<sup>1</sup>See Note 10.

<sup>2</sup>The required outer covering on some single-conductor cables may be integral with the insulation.

<sup>3</sup>All types listed in Table 400.4 shall have individual conductors twisted together except for Types HPN, SP-1, SP-2, SP-3, SPE-1, SPE-2, SPE-3, SPT-1, SPT-2, SPT-3, TPT, NISP-1, NISP-2, NISPT-1, NISPT-2, NISPE-1, NISPE-2, and three-conductor parallel versions of SRD, SRDE, and SRDT.

<sup>4</sup>Types TPT and TST shall be permitted in lengths not exceeding 2.5 m (8 ft) where attached directly, or by means of a special type of plug, to a portable appliance rated at 50 watts or less and of such nature that extreme flexibility of the cord is essential.

<sup>5</sup>Rubber-filled or varnished cambric tapes shall be permitted as a substitute for the inner braids.

<sup>6</sup>Types G, G-GC, S, SC, SCE, SCT, SE, SEO, SEOO, SO, SOO, ST, STO, STOO, PPE, and W shall be permitted for use on theater stages, in garages, and elsewhere where flexible cords are permitted by this Code.

<sup>7</sup>Elevator traveling cables for operating control and signal circuits shall contain nonmetallic fillers as necessary to maintain concentricity. Cables shall have steel supporting members as required for suspension by 620.41. In locations subject to excessive moisture or corrosive vapors or gases, supporting members of other materials shall be permitted. Where steel supporting members are used, they shall run straight through the center of the cable assembly and shall not be cabled with the copper strands of any conductor.

In addition to conductors used for control and signaling circuits, Types E, EO, ETP, and ETT elevator cables shall be permitted to incorporate in the construction one or more 20 AWG telephone conductor pairs, one or more coaxial cables, or one or more optical fibers. The 20 AWG conductor pairs shall be permitted to be covered with suitable shielding for telephone, audio, or higher frequency communications circuits; the coaxial cables consist of a center conductor, insulation, and shield for use in video or other radio frequency communications circuits. The optical fiber shall be suitably covered with flame-retardant thermoplastic. The insulation of the conductors shall be rubber or thermoplastic of thickness not less than specified for the other conduc-

tors of the particular type of cable. Metallic shields shall have their own protective covering. Where used, these components shall be permitted to be incorporated in any layer of the cable assembly but shall not run straight through the center.

<sup>8</sup>The third conductor in Type HPN shall be used as an equipment grounding conductor only. The insulation of the equipment grounding conductor for Types SPE-1, SPE-2, SPE-3, SPT-1, SPT-2, SPT-3, NISPT-1, NISPT-2, NISPE-1, and NISPE-2 shall be permitted to be thermoset polymer.

<sup>9</sup>The individual conductors of all cords, except those of heat-resistant cords, shall have a thermoset or thermoplastic insulation, except that the equipment grounding conductor where used shall be in accordance with 400.23(B).

<sup>10</sup>Where the voltage between any two conductors exceeds 300, but does not exceed 600, flexible cord of 10 AWG and smaller shall have thermoset or thermoplastic insulation on the individual conductors at least 1.14 mm (45 mils) in thickness, unless Type S, SE, SEO, SEOO, SO, SOO, ST, STO, or STOO cord is used.

<sup>11</sup>Insulations and outer coverings that meet the requirements as flame retardant, limited smoke, and are so listed, shall be permitted to be marked for limited smoke after the code type designation.

<sup>12</sup>Elevator cables in sizes 20 AWG through 14 AWG are rated 300 volts, and sizes 10 through 2 are rated 600 volts. 12 AWG is rated 300 volts with a 0.76-mm (30-mil) insulation thickness and 600 volts with a 1.14-mm (45-mil) insulation thickness.

<sup>13</sup>Conductor size for Types EV, EVJ, EVE, EVJE, EVT, and EVJT cables apply to nonpower-limited circuits only. Conductors of power-limited (data, signal, or communications) circuits may extend beyond the stated AWG size range. All conductors shall be insulated for the same cable voltage rating.

<sup>14</sup>Insulation thickness for Types EV, EVJ, EVEJE, EVT, and EVJT cables of nylon construction is indicated in parentheses.

<sup>15</sup>Cords that comply with the requirements for outdoor cords and are so listed shall be permitted to be designated as weather and water resistant with the suffix “W” after the code type designation. Cords with the “W” suffix are suitable for use in wet locations and are sunlight resistant.

Table 400.4 had minor editorial changes for the 2011 Code. There were no technical changes to the table.

Type G-GC cable is similar to Type G cable, except that it incorporates an insulated ground-check (GC) conductor. The ground-check conductor is used as part of a low-voltage circuit that monitors the grounding conductor continuity. Notes 13 and 14 to Table 400.4 coordinate these cable types with Article 625, Electric Vehicle Charging System.

## 400.5 Ampacities for Flexible Cords and Cables

(A) **Ampacity Tables.** Table 400.5(A)(1) provides the allowable ampacities, and Table 400.5(A)(2) provides the ampacities for flexible cords and cables with not more than three current-carrying conductors. These tables shall be used in conjunction with applicable end-use product standards to ensure selection of the proper size and type. Where cords are used in ambient temperatures other than 30°C (86°F), the temperature correction factors from Table 310.15(B)(2)(a)

that correspond to the temperature rating of the cord shall be applied to the ampacity in Table 400.5(A)(2). Where the number of current-carrying conductors exceeds three, the allowable ampacity or the ampacity of each conductor shall be reduced from the 3-conductor rating as shown in Table 400.5(A)(3).

This section had a minor editorial reorganization for the 2011 *Code*. Tables 400.5(A) and (B) were renumbered as 400.5(A)(1) and 400.5(A)(2), respectively. In addition, the third sentence to 400.5(A) makes it clear that adjustment factors also apply to temperatures below 30°C as well as temperatures above 30°C.

Where power cables are used in an ambient temperature exceeding 30°C (86°F), 400.5 requires “correction factors” be applied to the ampacities in Table 400.5(A)(2). This provision parallels the Article 310 requirements for ampacity correction of single conductors used in elevated ambient temperatures. In fact, the ambient correction factors that are to be used for power cables are those specified in Table 310.15(B)(16). The specific correction factor to be applied is predicated on the temperature rating of the power cable.

### Calculation Example

A 200-ampere feeder using Type W portable power cable is to be installed to distribution equipment on a floating pier, as permitted by 555.13. The specifications for the project indicate that the design ambient temperature is 95°F. The feeder is rated 208Y/120 volts, 3-phase, 4-wire, and due to the load characteristics, the grounded (neutral) conductor is to be counted as a current-carrying conductor per 400.5(A). The Type W portable power cable has copper conductors and a 90°C temperature rating. Determine the minimum ampacity for the feeder.

### Solution

STEP 1. Determine the minimum ampacity for conductors based on application of correction factors.

Calculated minimum feeder ampacity before adjustment factors [includes 215.2(A)(1) and 215.3 increase in size for continuous load] = 200 amperes

Ampacity adjustment factor for 4 current-carrying conductors = 80% of “3 current-carrying conductor (F)” column in Table 400.5(A)(3).

**TABLE 400.5(A)(1) Allowable Ampacity for Flexible Cords and Cables [Based on Ambient Temperature of 30°C (86°F). See 400.13 and Table 400.4.]**
