Definitions for *remote machine room and control room (for elevator, dumbwaiter)* and *remote machinery space and control space (for elevator, dumbwaiter)* describe elevator and dumbwaiter equipment rooms and areas that are not directly attached to the outside of the hoistway. These terms are used in various requirements of Article 620 and correlate with their use in ASME A17.1-2007.

**Control Room (for Elevator, Dumbwaiter).** An enclosed control space outside the hoistway, intended for full bodily entry, that contains the elevator motor controller. The room could also contain electrical and/or mechanical equipment used directly in connection with the elevator or dumbwaiter but not the electric driving machine or the hydraulic machine.

**Control Space (for Elevator, Dumbwaiter).** A space inside or outside the hoistway, intended to be accessed with or

without full bodily entry, that contains the elevator motor controller. This space could also contain electrical and/or mechanical equipment used directly in connection with the elevator or dumbwaiter but not the electrical driving machine or the hydraulic machine.

**Control System.** The overall system governing the starting, stopping, direction of motion, acceleration, speed, and retardation of the moving member.

**Controller, Motion.** The electrical device(s) for that part of the control system that governs the acceleration, speed, retardation, and stopping of the moving member.

**Controller, Motor.** The operative units of the control system comprised of the starter device(s) and power conversion equipment used to drive an electric motor, or the pumping unit used to power hydraulic control equipment.

**Controller, Operation.** The electrical device(s) for that part of the control system that initiates the starting, stopping, and direction of motion in response to a signal from an operating device.

**Machine Room (for Elevator, Dumbwaiter).** An enclosed machinery space outside the hoistway, intended for full bodily entry, that contains the electrical driving machine or the hydraulic machine. The room could also contain electrical and/or mechanical equipment used directly in connection with the elevator or dumbwaiter.

**Machinery Space (for Elevator, Dumbwaiter).** A space inside or outside the hoistway, intended to be accessed with or without full bodily entry, that contains elevator or dumbwaiter mechanical equipment, and could also contain electrical equipment used directly in connection with the elevator or dumbwaiter. This space could also contain the electrical driving machine or the hydraulic machine.

**Operating Device.** The car switch, pushbuttons, key or toggle switch(s), or other devices used to activate the operation controller.

**Remote Machine Room and Control Room (for Elevator, Dumbwaiter).** A machine room or control room that is not attached to the outside perimeter or surface of the walls, ceiling, or floor of the hoistway.

**Remote Machinery Space and Control Space (for Elevator, Dumbwaiter).** A machinery space or control space that is not within the hoistway, machine room, or control room and that is not attached to the outside perimeter or surface of the walls, ceiling, or floor of the hoistway.

**Signal Equipment.** Includes audible and visual equipment such as chimes, gongs, lights, and displays that convey information to the user.

Informational Note No. 1: The motor controller, motion controller, and operation controller may be located in a single enclosure or a combination of enclosures.

Informational Note No. 2: Informational Note Figure 620.2 is for information only.

Informational Note Figure 620.2 illustrates a typical elevator control system. The figure does not suggest that every elevator control system should have these exact components.

The definitions in 620.2 and informational note Figure 620.2 separate the control system into its functional parts. Article 620 uses the definitions to address and specify the proper safety concerns of motor controllers, motion controllers, and operation controllers.

### 620.3 Voltage Limitations

The supply voltage shall not exceed 300 volts between conductors unless otherwise permitted in 620.3(A) through (C).

**(A) Power Circuits.** Branch circuits to door operator controllers and door motors and branch circuits and feeders to motor controllers, driving machine motors, machine brakes, and motor-generator sets shall not have a circuit voltage in excess of 600 volts. Internal voltages of power conversion equipment and functionally associated equipment, and the operating voltages of wiring interconnecting the equipment, shall be permitted to be higher, provided that all such equipment and wiring shall be listed for the higher voltages. Where the voltage exceeds 600 volts, warning labels or signs that read “DANGER — HIGH VOLTAGE” shall be attached to the equipment and shall be plainly visible.

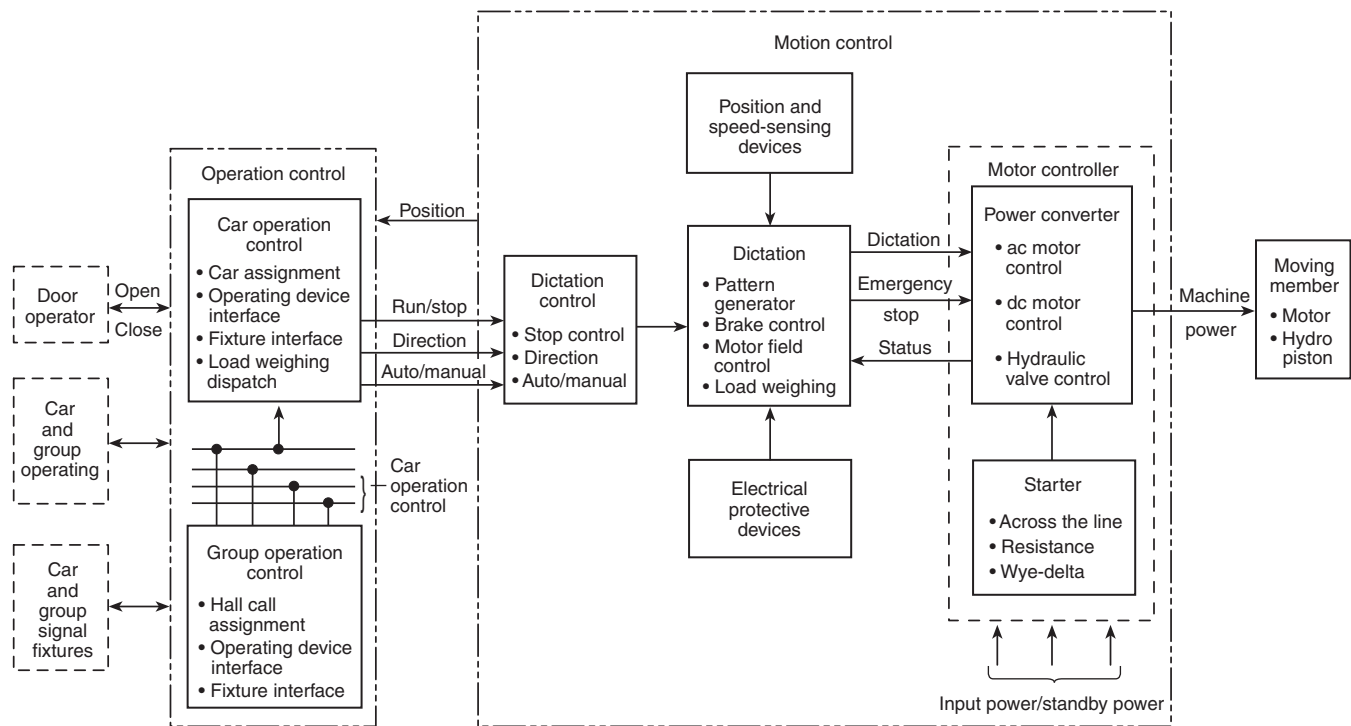

**(B) Lighting Circuits.** Lighting circuits shall comply with the requirements of Article 410.

**(C) Heating and Air-Conditioning Circuits.** Branch circuits for heating and air-conditioning equipment located on the elevator car shall not have a circuit voltage in excess of 600 volts.

The voltage limitations for power, lighting, and heating and air-conditioning circuits are described in 620.3. Voltage limitations for power conversion units and functionally associated equipment were replaced with a requirement for a warning sign for voltages above 600 volts.

### 620.4 Live Parts Enclosed

All live parts of electrical apparatus in the hoistways, at the landings, in or on the cars of elevators and dumbwaiters, in the wellways or the landings of escalators or moving walks, or in the runways and machinery spaces of platform lifts and

**INFORMATIONAL NOTE FIGURE 620.2 Control System.**

stairway chairlifts shall be enclosed to protect against accidental contact.

Informational Note: See 110.27 for guarding of live parts (600 volts, nominal, or less).

### 620.5 Working Clearances

Working space shall be provided about controllers, disconnecting means, and other electrical equipment. The minimum working space shall be not less than that specified in 110.26(A).

Where conditions of maintenance and supervision ensure that only qualified persons examine, adjust, service, and maintain the equipment, the clearance requirements of 110.26(A) shall be waived as permitted in 620.5(A) through (D).

**(A) Flexible Connections to Equipment.** Electrical equipment in (A)(1) through (A)(4) shall be permitted to be provided with flexible leads to all external connections so that it can be repositioned to meet the clear working space requirements of 110.26(A):

- (1) Controllers and disconnecting means for dumbwaiters, escalators, moving walks, platform lifts, and stairway chairlifts installed in the same space with the driving machine

- (2) Controllers and disconnecting means for elevators installed in the hoistway or on the car
- (3) Controllers for door operators
- (4) Other electrical equipment installed in the hoistway or on the car

Due to the physical constraints of the locations where this equipment is typically installed and the necessity of performing diagnostic work on it while it is energized, 620.5(A) permits flexible leads on equipment so it can be moved to a location that meets the working clearance requirements of 110.26(A).

**(B) Guards.** Live parts of the electrical equipment are suitably guarded, isolated, or insulated, and the equipment can be examined, adjusted, serviced, or maintained while energized without removal of this protection.

Informational Note: See definition of *Exposed* in Article 100.

**(C) Examination, Adjusting, and Servicing.** Electrical equipment is not required to be examined, adjusted, serviced, or maintained while energized.

**(D) Low Voltage.** Uninsulated parts are at a voltage not greater than 30 volts rms, 42 volts peak, or 60 volts dc.

## II. Conductors

### 620.11 Insulation of Conductors

The insulation of conductors shall comply with 620.11(A) through (D).

**Informational Note:** One method of determining that conductors are flame retardant is by testing the conductors to the VW-1 (Vertical-Wire) Flame Test in ANSI/UL 1581-2001, *Reference Standard for Electrical Wires, Cables, and Flexible Cords*.

**(A) Hoistway Door Interlock Wiring.** The conductors to the hoistway door interlocks from the hoistway riser shall be flame retardant and suitable for a temperature of not less than 200°C (392°F). Conductors shall be Type SF or equivalent.

**(B) Traveling Cables.** Traveling cables used as flexible connections between the elevator or dumbwaiter car or counterweight and the raceway shall be of the types of elevator cable listed in Table 400.4 or other approved types.

**(C) Other Wiring.** All conductors in raceways shall have flame-retardant insulation.

Conductors shall be Type MTW, TF, TFF, TFN, TFFN, THHN, THW, THWN, TW, XHHW, hoistway cable, or any other conductor with insulation designated as flame retardant. Shielded conductors shall be permitted if such conductors are insulated for the maximum nominal circuit voltage applied to any conductor within the cable or raceway system.

**(D) Insulation.** All conductors shall have an insulation voltage rating equal to at least the maximum nominal circuit voltage applied to any conductor within the enclosure, cable, or raceway. Insulations and outer coverings that are marked for limited smoke and are so listed shall be permitted.

Hoistway door interlock wiring is required to be suitable for 200°C (392°F). See Table 310.104(A), Conductor Application and Insulations. See also Table 310.15(B)(18).

See Table 400.4 for approved types of elevator cables for use in hazardous (classified) and unclassified locations. See also Note 7 to Table 400.4. A characteristic equally important with respect to safety is the need to prevent twisting of cables as they travel up and down with the elevator or dumbwaiter.

### 620.12 Minimum Size of Conductors

The minimum size of conductors, other than conductors that form an integral part of control equipment, shall be in accordance with 620.12(A) and (B).

#### (A) Traveling Cables.

**(1) Lighting Circuits.** For lighting circuits, 14 AWG copper, 20 AWG copper or larger conductors shall be permitted in parallel, provided the ampacity is equivalent to at least that of 14 AWG copper.

**(2) Other Circuits.** For other circuits, 20 AWG copper.

**(B) Other Wiring.** 24 AWG copper. Smaller size listed conductors shall be permitted.

Section 620.12(A)(1) amends the general requirements for parallel conductors and permits 20 AWG and larger conductors to be installed in parallel for lighting circuits, provided that the combined ampacity of the paralleled conductors is not less than that of a 14 AWG conductor. This provision is unique to Article 620 and is an example of the structure of the *Code* as set forth in 90.3, in that a requirement in Chapter 6 modifies a general requirement from Chapter 3.

In general, the requirements of 310.10(H) provide the conditions under which conductors can be installed in parallel for power and lighting circuits. One of those conditions stipulates that the minimum size for parallel conductors is 1/0 AWG. In high-rise structures, the length of the elevator traveling cables is problematic with respect to maintaining an acceptable level of voltage drop for equipment on or within the car. To require compliance with the general rules for parallel conductors would result in exceedingly large traveling cables.

The use of conductors smaller than 24 AWG is permitted by 620.12(B) in response to the extensive use of electronics with lower currents provided that they are listed and have the necessary strength and durability for the conditions to which they will be exposed. One application is the shielded cables interconnecting various microprocessors in an elevator distributed control system.

### 620.13 Feeder and Branch-Circuit Conductors

Conductors shall have an ampacity in accordance with 620.13(A) through (D). With generator field control, the conductor ampacity shall be based on the nameplate current rating of the driving motor of the motor-generator set that supplies power to the elevator motor.

**Informational Note No. 1:** The heating of conductors depends on root-mean-square current values, which, with generator field control, are reflected by the nameplate current rating of the motor-generator driving motor rather than by the rating of the elevator motor, which represents actual but short-time and intermittent full-load current values.

**Informational Note No. 2:** See Figure 620.13.

FIGURE 620.13 Single-Line Diagram.

Figure 620.13 depicts the appropriate reference for each part of an elevator circuit.

**(A) Conductors Supplying Single Motor.** Conductors supplying a single motor shall have an ampacity not less than the percentage of motor nameplate current determined from 430.22(A) and (E).

Informational Note: Elevator motor currents, or those of similar functions, may exceed the nameplate value, but because they are inherently intermittent duty and the heating of the motor and conductors is dependent on the root-mean-square (rms) current value, conductors are sized for duty cycle service as shown in Table 430.22(E).

**(B) Conductors Supplying a Single Motor Controller.** Conductors supplying a single motor controller shall have an ampacity not less than the motor controller nameplate current rating, plus all other connected loads.

Informational Note: Motor controller nameplate current rating may be derived based on the rms value of the motor

current using an intermittent duty cycle and other control system loads, if applicable.

**(C) Conductors Supplying a Single Power Transformer.** Conductors supplying a single power transformer shall have an ampacity not less than the nameplate current rating of the power transformer plus all other connected loads.

Informational Note No. 1: The nameplate current rating of a power transformer supplying a motor controller reflects the nameplate current rating of the motor controller at line voltage (transformer primary).

Informational Note No. 2: See Informative Annex D, Example No. D10.

**(D) Conductors Supplying More Than One Motor, Motor Controller, or Power Transformer.** Conductors supplying more than one motor, motor controller, or power transformer shall have an ampacity not less than the sum of the nameplate current ratings of the equipment plus all other connected loads. The ampere ratings of motors to be used in the summation shall be determined from Table 430.22(E), 430.24 and 430.24, Exception No. 1.

Informational Note: See Informative Annex D, Example Nos. D9 and D10.

620.14 Feeder Demand Factor

Feeder conductors of less ampacity than required by 620.13 shall be permitted, subject to the requirements of Table 620.14.

TABLE 620.14 Feeder Demand Factors for Elevators

Number of Elevators on a Single Feeder	Demand Factor
1	1.00
2	0.95
3	0.90
4	0.85
5	0.82
6	0.79
7	0.77
8	0.75
9	0.73
10 or more	0.72

Informational Note: Demand factors are based on 50 percent duty cycle (i.e., half time on and half time off).

620.15 Motor Controller Rating

The motor controller rating shall comply with 430.83. The rating shall be permitted to be less than the nominal rating

of the elevator motor, when the controller inherently limits the available power to the motor and is marked as power limited.

Informational Note: For controller markings, see 430.8.

The inherent power-limiting ability of certain adjustable-speed drive controllers is the basis for permitting the controller to have a lower current or horsepower rating than that of the motor. To use a controller in this manner, the manufacturer's marking must indicate that it is power limiting.

### III. Wiring

#### 620.21 Wiring Methods

Conductors and optical fibers located in hoistways, in escalator and moving walk wellways, in platform lifts, stairway chairlift runways, machinery spaces, control spaces, in or on cars, in machine rooms and control rooms, not including the traveling cables connecting the car or counterweight and hoistway wiring, shall be installed in rigid metal conduit, intermediate metal conduit, electrical metallic tubing, rigid nonmetallic conduit, or wireways, or shall be Type MC, MI, or AC cable unless otherwise permitted in 620.21(A) through (C).

##### (A) Elevators.

##### (1) Hoistways.

(a) Cables used in Class 2 power-limited circuits shall be permitted to be installed between risers and signal equipment and operating devices, provided the cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

(b) Flexible cords and cables that are components of listed equipment and used in circuits operating at 30 volts rms or less or 42 volts dc or less shall be permitted in lengths not to exceed 1.8 m (6 ft), provided the cords and cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

(c) The following wiring methods shall be permitted in the hoistway in lengths not to exceed 1.8 m (6 ft):

- (1) Flexible metal conduit
- (2) Liquidtight flexible metal conduit
- (3) Liquidtight flexible nonmetallic conduit
- (4) Flexible cords and cables, or conductors grouped together and taped or corded, shall be permitted to be installed without a raceway. They shall be located to be protected from physical damage and shall be of a flame-retardant type and shall be part of the following:

- a. Listed equipment
- b. A driving machine, or
- c. A driving machine brake

Limited (6 ft) lengths of flexible cord and cable are permitted to be used on elevator cars, where the cord or cable is part of listed equipment such as transducers (position, velocity, direction) and the circuit is limited to 30 volts rms or 42 volts dc.

*Exception to 620.21(A)(1)(c)(1), (2), and (3): The conduit length shall not be required to be limited between risers and limit switches, interlocks, operating buttons, and similar devices.*

(d) A sump pump or oil recovery pump located in the pit shall be permitted to be cord connected. The cord shall be a hard usage oil-resistant type, of a length not to exceed 1.8 m (6 ft), and shall be located to be protected from physical damage.

##### (2) Cars.

(a) Flexible metal conduit, liquidtight flexible metal conduit, or liquidtight flexible nonmetallic conduit of metric designator 12 (trade size  $\frac{3}{8}$ ), or larger, not exceeding 1.8 m (6 ft) in length, shall be permitted on cars where so located as to be free from oil and if securely fastened in place.

*Exception: Liquidtight flexible nonmetallic conduit of metric designator 12 (trade size  $\frac{3}{8}$ ), or larger, as defined by 356.2(2), shall be permitted in lengths in excess of 1.8 m (6 ft).*

(b) Hard-service cords and junior hard-service cords that conform to the requirements of Article 400 (Table 400.4) shall be permitted as flexible connections between the fixed wiring on the car and devices on the car doors or gates. Hard-service cords only shall be permitted as flexible connections for the top-of-car operating device or the car-top work light. Devices or luminaires shall be grounded by means of an equipment grounding conductor run with the circuit conductors. Cables with smaller conductors and other types and thicknesses of insulation and jackets shall be permitted as flexible connections between the fixed wiring on the car and devices on the car doors or gates, if listed for this use.

(c) Flexible cords and cables that are components of listed equipment and used in circuits operating at 30 volts rms or less or 42 volts dc or less shall be permitted in lengths not to exceed 1.8 m (6 ft), provided the cords and cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

(d) The following wiring methods shall be permitted on the car assembly in lengths not to exceed 1.8 m (6 ft):

- (1) Flexible metal conduit
- (2) Liquidtight flexible metal conduit
- (3) Liquidtight flexible nonmetallic conduit
- (4) Flexible cords and cables, or conductors grouped together and taped or corded, shall be permitted to be installed without a raceway. They shall be located to be protected from physical damage and shall be of a flame-retardant type and shall be part of the following:
  - a. Listed equipment
  - b. A driving machine, or
  - c. A driving machine brake

The requirements of 620.21(A)(2)(d) describe the permitted wiring methods where a driving machine or driving machine brake is located on the car. In addition to flexible metal and nonmetallic conduits, the use of single conductors that are taped or corded together is permitted. This use includes rack-and-pinion or screw column drives located on cars. See also 620.71(B).

### (3) Within Machine Rooms, Control Rooms, and Machinery Spaces and Control Spaces.

(a) Flexible metal conduit, liquidtight flexible metal conduit, or liquidtight flexible nonmetallic conduit of metric designator 12 (trade size  $\frac{3}{8}$ ), or larger, not exceeding 1.8 m (6 ft) in length, shall be permitted between control panels and machine motors, machine brakes, motor-generator sets, disconnecting means, and pumping unit motors and valves.

*Exception: Liquidtight flexible nonmetallic conduit metric designator 12 (trade size  $\frac{3}{8}$ ) or larger, as defined in 356.2(2), shall be permitted to be installed in lengths in excess of 1.8 m (6 ft).*

(b) Where motor-generators, machine motors, or pumping unit motors and valves are located adjacent to or underneath control equipment and are provided with extra-length terminal leads not exceeding 1.8 m (6 ft) in length, such leads shall be permitted to be extended to connect directly to controller terminal studs without regard to the carrying-capacity requirements of Articles 430 and 445. Auxiliary gutters shall be permitted in machine and control rooms between controllers, starters, and similar apparatus.

(c) Flexible cords and cables that are components of listed equipment and used in circuits operating at 30 volts rms or less or 42 volts dc or less shall be permitted in lengths not to exceed 1.8 m (6 ft), provided the cords and cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

(d) On existing or listed equipment, conductors shall also be permitted to be grouped together and taped or corded without being installed in a raceway. Such cable groups shall be supported at intervals not over 900 mm (3 ft) and located so as to be protected from physical damage.

(e) Flexible cords and cables in lengths not to exceed 1.8 m (6 ft) that are of a flame-retardant type and located to be protected from physical damage shall be permitted in these rooms and spaces without being installed in a raceway. They shall be part of the following:

- (1) Listed equipment
- (2) A driving machine, or
- (3) A driving machine brake

**(4) Counterweight.** The following wiring methods shall be permitted on the counterweight assembly in lengths not to exceed 1.8 m (6 ft):

- (1) Flexible metal conduit
- (2) Liquidtight flexible metal conduit
- (3) Liquidtight flexible nonmetallic conduit
- (4) Flexible cords and cables, or conductors grouped together and taped or corded, shall be permitted to be installed without a raceway. They shall be located to be protected from physical damage, shall be of a flame-retardant type, and shall be part of the following:
  - a. Listed equipment
  - b. A driving machine, or
  - c. A driving machine brake

### (B) Escalators.

**(1) Wiring Methods.** Flexible metal conduit, liquidtight flexible metal conduit, or liquidtight flexible nonmetallic conduit shall be permitted in escalator and moving walk wellways. Flexible metal conduit or liquidtight flexible conduit of metric designator 12 (trade size  $\frac{3}{8}$ ) shall be permitted in lengths not in excess of 1.8 m (6 ft).

*Exception: Metric designator 12 (trade size  $\frac{3}{8}$ ), nominal, or larger liquidtight flexible nonmetallic conduit, as defined in 356.2(2), shall be permitted to be installed in lengths in excess of 1.8 m (6 ft).*

**(2) Class 2 Circuit Cables.** Cables used in Class 2 power-limited circuits shall be permitted to be installed within escalators and moving walkways, provided the cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

**(3) Flexible Cords.** Hard-service cords that conform to the requirements of Article 400 (Table 400.4) shall be permitted as flexible connections on escalators and moving walk control panels and disconnecting means where the entire control

panel and disconnecting means are arranged for removal from machine spaces as permitted in 620.5.

### (C) Platform Lifts and Stairway Chairlift Raceways.

**(1) Wiring Methods.** Flexible metal conduit or liquidtight flexible metal conduit shall be permitted in platform lifts and stairway chairlift runways and machinery spaces. Flexible metal conduit or liquidtight flexible conduit of metric designator 12 (trade size  $\frac{3}{8}$ ) shall be permitted in lengths not in excess of 1.8 m (6 ft).

*Exception: Metric designator 12 (trade size  $\frac{3}{8}$ ) or larger liquidtight flexible nonmetallic conduit, as defined in 356.2(2), shall be permitted to be installed in lengths in excess of 1.8 m (6 ft).*

**(2) Class 2 Circuit Cables.** Cables used in Class 2 power-limited circuits shall be permitted to be installed within platform lifts and stairway chairlift runways and machinery spaces, provided the cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

**(3) Flexible Cords and Cables.** Flexible cords and cables that are components of listed equipment and used in circuits operating at 30 volts rms or less or 42 volts dc or less shall be permitted in lengths not to exceed 1.8 m (6 ft), provided the cords and cables are supported and protected from physical damage and are of a jacketed and flame-retardant type.

## 620.22 Branch Circuits for Car Lighting, Receptacle(s), Ventilation, Heating, and Air-Conditioning

**(A) Car Light Source.** A separate branch circuit shall supply the car lights, receptacle(s), auxiliary lighting power source, and ventilation on each elevator car. The overcurrent device protecting the branch circuit shall be located in the elevator machine room or control room/machinery space or control space.

Required lighting shall not be connected to the load side of a ground-fault circuit interrupter.

Section 620.22(A) does not permit elevator car lighting to be supplied from wiring connected to the load side of a ground-fault circuit interrupter. A service receptacle installed on an elevator car top is required to be a GFCI-type device, and because the car lights and receptacle are supplied from the same branch circuit, this requirement ensures that GFCI operation will not also interrupt power to the car lighting. The same requirement is found in 620.23(A) and 620.24(A) for machine room lighting and hoistway pit lighting. See Exhibit 620.2 for an example of a disconnecting means with

overcurrent protection for the separate branch circuit supplying elevator car lighting, receptacle(s), and ventilation equipment.

**(B) Air-Conditioning and Heating Source.** A dedicated branch circuit shall supply the air-conditioning and heating units on each elevator car. The overcurrent device protecting the branch circuit shall be located in the elevator machine room or control room/machinery space or control space.

The requirements in 620.22(A) and (B) specify that the overcurrent devices protecting the branch circuits for elevator car lighting and heating and air conditioning are to be located in the elevator machine room or control room or in the elevator machinery or control space. This requirement facilitates ease of maintenance and troubleshooting and correlates with similar requirements in other North American elevator standards.

## 620.23 Branch Circuits for Machine Room or Control Room/Machinery Space or Control Space Lighting and Receptacle(s)

**(A) Separate Branch Circuit.** A separate branch circuit shall supply the machine room or control room/machinery space or control space lighting and receptacle(s).

Required lighting shall not be connected to the load side of a ground-fault circuit interrupter.

Luminaires are not permitted to be connected to the load side of a GFCI device of any kind to prevent interruption of power to the machine room lighting resulting from the operation of a ground-fault circuit interrupter.

**(B) Lighting Switch.** The machine room or control room/machinery space or control space lighting switch shall be located at the point of entry.

**(C) Duplex Receptacle.** At least one 125-volt, single-phase, 15- or 20-ampere duplex receptacle shall be provided in each machine room or control room and machinery space or control space.

Informational Note: See ASME A17.1-2007/CSA B44-07, *Safety Code for Elevators and Escalators*, for illumination levels.

The receptacles required by 620.23 and 620.24 are also required to be provided with GFCI protection for personnel (see 620.85). Luminaires are not permitted to be connected

to the load side of GFCI devices. See also the commentary following 620.23(A).

ASME A17.1-2004, *Safety Code for Elevators and Escalators*, requires a minimum of 5 ft-candles (54 lux) at the pit floor and requires luminaires to be externally guarded to prevent accidental breakage.

Luminaires in pits should be mounted so that the car or counterweight does not strike them when on fully compressed buffers.

### 620.24 Branch Circuit for Hoistway Pit Lighting and Receptacle(s)

**(A) Separate Branch Circuit.** A separate branch circuit shall supply the hoistway pit lighting and receptacle(s).

Required lighting shall not be connected to the load side of a ground-fault circuit interrupter.

**(B) Lighting Switch.** The lighting switch shall be so located as to be readily accessible from the pit access door.

**(C) Duplex Receptacle.** At least one 125-volt, single-phase, 15- or 20-ampere duplex receptacle shall be provided in the hoistway pit.

Informational Note: See ASME A17.1-2007/CSA B44-07, *Safety Code for Elevators and Escalators*, for illumination levels.

### 620.25 Branch Circuits for Other Utilization Equipment

**(A) Additional Branch Circuits.** Additional branch circuit(s) shall supply utilization equipment not identified in 620.22, 620.23, and 620.24. Other utilization equipment shall be restricted to that equipment identified in 620.1.

**(B) Overcurrent Devices.** The overcurrent devices protecting the branch circuit(s) shall be located in the elevator machinery room or control room/machinery space or control space.

## IV. Installation of Conductors

### 620.32 Metal Wireways and Nonmetallic Wireways

The sum of the cross-sectional area of the individual conductors in a wireway shall not be more than 50 percent of the interior cross-sectional area of the wireway.

Vertical runs of wireways shall be securely supported at intervals not exceeding 4.5 m (15 ft) and shall have not more than one joint between supports. Adjoining wireway sections shall be securely fastened together to provide a rigid joint.

### 620.33 Number of Conductors in Raceways

The sum of the cross-sectional area of the individual conductors in raceways shall not exceed 40 percent of the interior cross-sectional area of the raceway, except as permitted in 620.32 for wireways.

### 620.34 Supports

Supports for cables or raceways in a hoistway or in an escalator or moving walk wellway or platform lift and stairway chairlift runway shall be securely fastened to the guide rail; escalator or moving walk truss; or to the hoistway, wellway, or runway construction.

### 620.35 Auxiliary Gutters

Auxiliary gutters shall not be subject to the restrictions of 366.12(2) covering length or of 366.22 covering number of conductors.

### 620.36 Different Systems in One Raceway or Traveling Cable

Optical fiber cables and conductors for operating devices, operation and motion control, power, signaling, fire alarm, lighting, heating, and air-conditioning circuits of 600 volts or less shall be permitted to be run in the same traveling cable or raceway system if all conductors are insulated for the maximum voltage applied to any conductor within the cables or raceway system and if all live parts of the equipment are insulated from ground for this maximum voltage. Such a traveling cable or raceway shall also be permitted to include shielded conductors and/or one or more coaxial cables if such conductors are insulated for the maximum voltage applied to any conductor within the cable or raceway system. Conductors shall be permitted to be covered with suitable shielding for telephone, audio, video, or higher frequency communications circuits.

The use of greater numbers of individual cables and of much longer cables in tall buildings raises the possibility of the multiple cable loops becoming twisted. To eliminate the practice of tying other cables to the traveling cable, one elevator cable or raceway is permitted to enclose optical fiber cables and all the conductors for power, control, lighting, video, fire alarm, and communications circuits if all conductors are insulated for the maximum voltage applied to any conductor within the cable or raceway and all live parts are also insulated from ground for the maximum voltage present.

Power-limited and non-power-limited fire alarm conductors are permitted in the same raceway or traveling cable as power and other types of signaling conductors. All power,

signaling, and fire alarm conductors are to be insulated for the maximum voltage applied to any conductor in the raceway or cable.

### 620.37 Wiring in Hoistways, Machine Rooms, Control Rooms, Machinery Spaces, and Control Spaces

**(A) Uses Permitted.** Only such electrical wiring, raceways, and cables used directly in connection with the elevator or dumbwaiter, including wiring for signals, for communication with the car, for lighting, heating, air conditioning, and ventilating the elevator car, for fire detecting systems, for pit sump pumps, and for heating, lighting, and ventilating the hoistway, shall be permitted inside the hoistway, machine rooms, control rooms, machinery spaces, and control spaces.

**(B) Lightning Protection.** Bonding of elevator rails (car and/or counterweight) to a lightning protection system grounding down conductor(s) shall be permitted. The lightning protection system grounding down conductor(s) shall not be located within the hoistway. Elevator rails or other hoistway equipment shall not be used as the grounding down conductor for lightning protection systems.

Informational Note: See 250.106 for bonding requirements. For further information, see NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*.

Section 620.37(A) prohibits equipment and wiring not associated with the elevator from being installed in elevator machine rooms and hoistways. Only electrical equipment and wiring used directly in connection with the elevator may be installed inside the hoistway and the machine room.

Where a lightning protection system is provided, and where a lightning protection system grounding “down” conductor(s) located outside the hoistway is within a critical horizontal distance of the elevator rails, bonding of the rails to the lightning protection system grounding down conductor(s) is required by NFPA 780, *Standard for the Installation of Lightning Protection Systems*. The requirements of 620.37(B) provide the necessary correlation for this bonding of the elevator rails to occur. Bonding prevents a dangerous side flash between the lightning protection system grounding down conductor(s) and the elevator rails. A lightning strike on the building air terminal will be conducted through the lightning protection system grounding down conductor(s), and, if the elevator rails are not at the same potential as the lightning protection system grounding down conductor(s), a side flash may occur. Generally, down conductors are installed vertically near the perimeter of the structure.

**(C) Main Feeders.** Main feeders for supplying power to elevators and dumbwaiters shall be installed outside the hoistway unless as follows:

- (1) By special permission, feeders for elevators shall be permitted within an existing hoistway if no conductors are spliced within the hoistway.
- (2) Feeders shall be permitted inside the hoistway for elevators with driving machine motors located in the hoistway or on the car or counterweight.

### 620.38 Electrical Equipment in Garages and Similar Occupancies

Electrical equipment and wiring used for elevators, dumbwaiters, escalators, moving walks, and platform lifts and stairway chairlifts in garages shall comply with the requirements of Article 511.

Informational Note: Garages used for parking or storage and where no repair work is done in accordance with 511.3 are not classified.

## V. Traveling Cables

### 620.41 Suspension of Traveling Cables

Traveling cables shall be suspended at the car and hoistways’ ends, or counterweight end where applicable, so as to reduce the strain on the individual copper conductors to a minimum.

Traveling cables shall be supported by one of the following means:

- (1) By their steel supporting member(s)
- (2) By looping the cables around supports for unsupported lengths less than 30 m (100 ft)
- (3) By suspending from the supports by a means that automatically tightens around the cable when tension is increased for unsupported lengths up to 60 m (200 ft)

Informational Note: Unsupported length for the hoistway suspension means is that length of cable as measured from the point of suspension in the hoistway to the bottom of the loop, with the elevator car located at the bottom landing. Unsupported length for the car suspension means is that length of cable as measured from the point of suspension on the car to the bottom of the loop, with the elevator car located at the top landing.

Traveling cables between fixed suspension points are not required to be installed in a raceway. If the fixed suspension point is on top of the car, the cables on the side of the car might be exposed. Suitable guards are necessary to protect these cables from damage. If the suspension point is under the car, the cables might be run up the side of the car to the car’s top junction box. If the runs are over 6 ft, the cables are

elevator car lights required by 620.51. These disconnecting means are installed in the elevator machine room.

**(A) Type.** The disconnecting means shall be an enclosed externally operable fused motor circuit switch or circuit breaker capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment.

The disconnecting means shall be a listed device.

Informational Note: For additional information, see ASME A17.1-2007/CSA B44-07, *Safety Code for Elevators and Escalators*.

*Exception No. 1: Where an individual branch circuit supplies a platform lift, the disconnecting means required by 620.51(C)(4) shall be permitted to comply with 430.109(C). This disconnecting means shall be listed and shall be capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment.*

*Exception No. 2: Where an individual branch circuit supplies a stairway chairlift, the stairway chairlift shall be permitted to be cord-and-plug-connected, provided it complies with 422.16(A) and the cord does not exceed 1.8 m (6 ft) in length.*

**(B) Operation.** No provision shall be made to open or close this disconnecting means from any other part of the premises. If sprinklers are installed in hoistways, machine rooms, control rooms, machinery spaces, or control spaces, the disconnecting means shall be permitted to automatically open the power supply to the affected elevator(s) prior to the application of water. No provision shall be made to automatically close this disconnecting means. Power shall only be restored by manual means.

Informational Note: To reduce hazards associated with water on live elevator electrical equipment.

ASME A17.1-2007, *Safety Code for Elevators and Escalators*, Rule 2.8.3.3.2, requires that where sprinklers are installed in hoistways, machine rooms, or machinery spaces, a

means must be provided to automatically disconnect the main line power supply to the affected elevator(s) upon or prior to the application of water. Water on elevator electrical equipment can result in hazards such as uncontrolled car movement (wet machine brakes), movement of elevator with open doors (water on safety circuits bypassing car and/or hoistway door interlocks), and shock hazards.

Automatic disconnection of the main line power supply is not required by ASME A17.1 where hoistways and machine rooms are not sprinklered. NFPA 13, *Standard for the Installation of Sprinkler Systems*, provides requirements for the installation of sprinklers in machine rooms, hoistways, and pits.

Elevator shutdown is generally accomplished through the use of heat detectors located near sprinkler heads. The heat detectors are designed to actuate and generate an alarm signal prior to water discharge from the sprinkler heads. An output control relay powered by the fire alarm system then provides a monitored output to the main line disconnecting means control circuit, which activates the shunt trip. This practice ensures that all components have secondary power and are monitored for integrity, as required by NFPA 72®, *National Fire Alarm and Signaling Code*. Stand-alone heat detectors connected directly to the elevator disconnecting means control circuit are not monitored for integrity, have no secondary power supply, and are not permitted by NFPA 72.

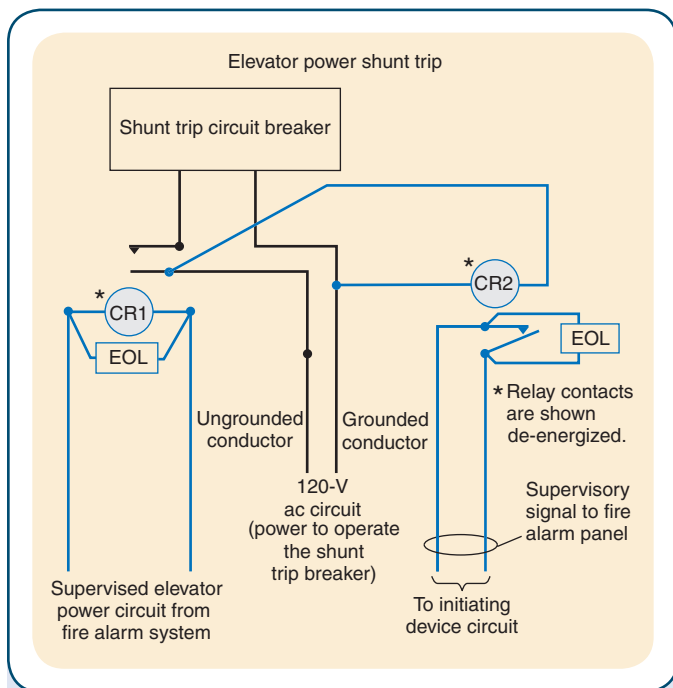

Elevator shutdown can occur even if the car is not at a landing. In order to avoid trapping occupants in elevator car(s) when the main power to the elevator driving machine is interrupted due to sprinkler activation, Rule 2.27.3.2 of ASME A17.1 requires installation of a fire alarm initiating device(s) in sprinklered hoistways for the purposes of initiating elevator car(s) recall before the main line power is disconnected. This operation is referred to as “Phase I Emergency Recall” in the ASME code. See Section 21.4 of NFPA 72-2010 for additional requirements relating to the fire alarm system and elevator shutdown.

Exhibit 620.3 illustrates a typical method of supervising control power using a fire alarm system. Loss of control power produces a supervisory signal at the fire alarm control unit that then would be investigated.

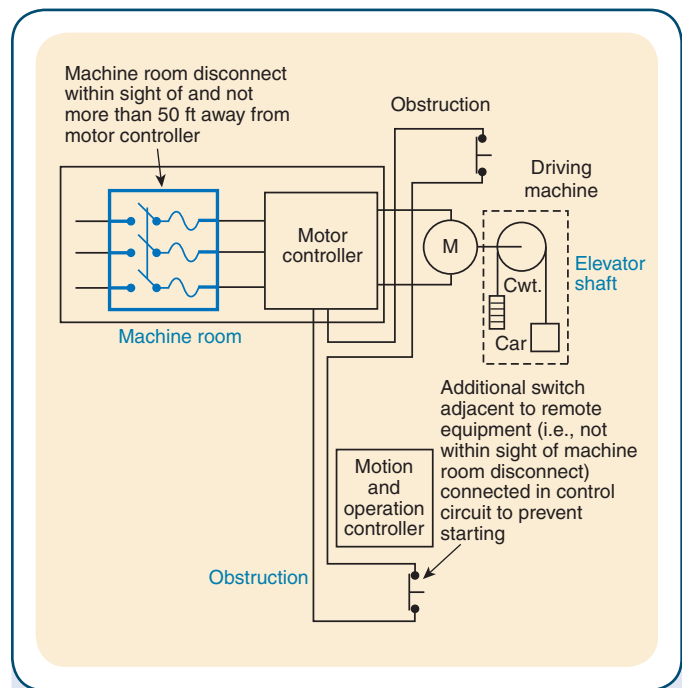

**(C) Location.** The disconnecting means shall be located where it is readily accessible to qualified persons.

**(1) On Elevators Without Generator Field Control.** On elevators without generator field control, the disconnecting means shall be located within sight of the motor controller. Where the motor controller is located in the elevator hoistway, the disconnecting means required by 620.51(A) shall be located in a machinery space, machine room, control space or control room outside the hoistway; and an additional, non-fused enclosed externally operable motor circuit

**EXHIBIT 620.3** Typical method of control power supervision using a fire alarm control unit.

**EXHIBIT 620.4** Disconnecting means for driving machines or motion and operation controllers not within sight of the main line disconnecting means. (Courtesy of ASME)

switch capable of being locked in the open position to disconnect all ungrounded main power-supply conductors shall be located within sight of the motor controller. The additional switch shall be a listed device and shall comply with 620.91(C).

The provision for locking or adding a lock to the disconnecting means, required by this section, shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted.

Driving machines or motion and operation controllers not within sight of the disconnecting means shall be provided with a manually operated switch installed in the control circuit to prevent starting. The manually operated switch(es) shall be installed adjacent to this equipment.

Where the driving machine of an electric elevator or the hydraulic machine of a hydraulic elevator is located in a remote machine room or remote machinery space, a single means for disconnecting all ungrounded main power-supply conductors shall be provided and be capable of being locked in the open position.

Exhibit 620.4 illustrates the requirement on disconnecting means for driving machines or motion and operation controllers not within sight of the main line disconnecting means.

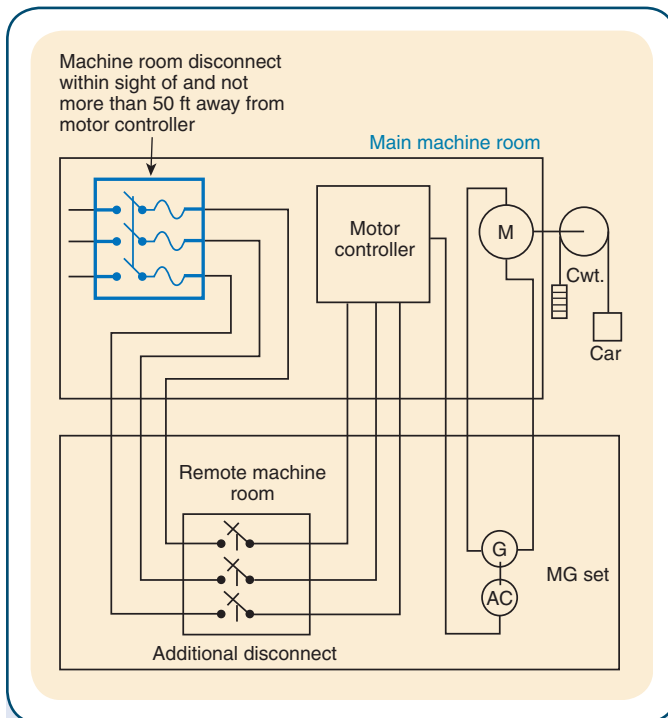

**(2) On Elevators with Generator Field Control.** On elevators with generator field control, the disconnecting means shall be located within sight of the motor controller for the driving motor of the motor-generator set. Driving machines, motor-generator sets, or motion and operation controllers not within sight of the disconnecting means shall be provided with a manually operated switch installed in the control circuit to prevent starting. The manually operated switch(es) shall be installed adjacent to this equipment.

Where the driving machine or the motor-generator set is located in a remote machine room or remote machinery space, a single means for disconnecting all ungrounded main power-supply conductors shall be provided and be capable of being locked in the open position.

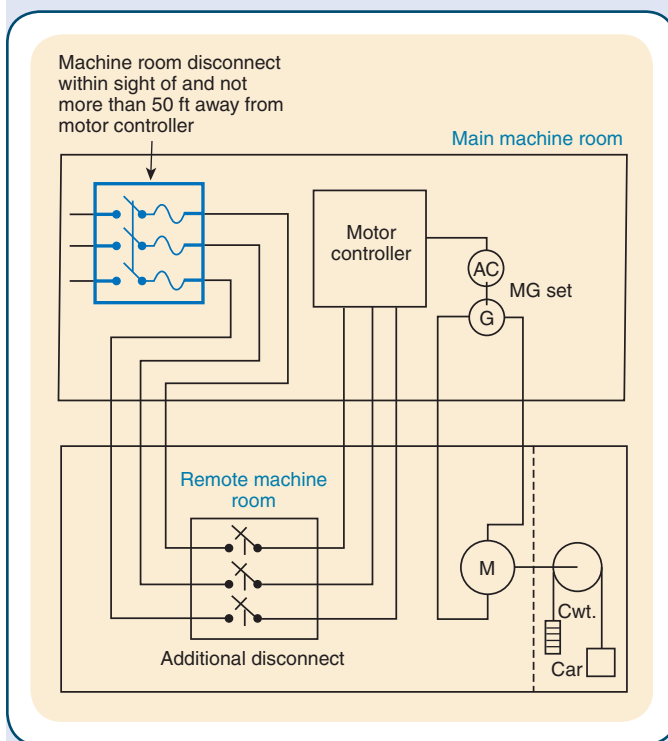

See Exhibits 620.5 and 620.6 for examples of disconnecting means for a motor-generator set and for driving machines in remote locations.

**(3) On Escalators and Moving Walks.** On escalators and moving walks, the disconnecting means shall be installed in the space where the controller is located.

The local emergency stop control at the escalator location shown in Exhibit 620.7, which is required by 6.1.6.3.1 of ASME A.17.1b for passenger safety, cannot be used as the

**EXHIBIT 620.5** Disconnecting means for a motor-generator (MG) set in a remote location. (Courtesy of ASME)

**EXHIBIT 620.6** Disconnecting means for driving machines in a remote location. (Courtesy of ASME)

**EXHIBIT 620.7** Emergency stop button installed at the escalator location to provide a local means to shut down the equipment in the event of a passenger accident. This is not considered to be the disconnecting means required by 620.51(C)(3).

disconnecting means required by this section. The disconnecting means for the escalator must meet the requirements of 620.51(A) covering the type of disconnecting means device required to be used as for the equipment covered within the scope of Article 620.

**(4) On Platform Lifts and Stairway Chairlifts.** On platform lifts and stairway chairlifts, the disconnecting means shall be located within sight of the motor controller.

**(D) Identification and Signs.** Where there is more than one driving machine in a machine room, the disconnecting means shall be numbered to correspond to the identifying number of the driving machine that they control.

The disconnecting means shall be provided with a sign to identify the location of the supply side overcurrent protective device.

The intent of the sign requirements for the location of supply-side overcurrent devices is to assist the elevator mechanic in troubleshooting a power interruption to the elevator disconnecting means.

## 620.52 Power from More Than One Source

**(A) Single-Car and Multicar Installations.** On single-car and multicar installations, equipment receiving electrical power from more than one source shall be provided with a disconnecting means for each source of electrical power. The disconnecting means shall be within sight of the equipment served.

**(B) Warning Sign for Multiple Disconnecting Means.**

Where multiple disconnecting means are used and parts of the controllers remain energized from a source other than the one disconnected, a warning sign shall be mounted on or next to the disconnecting means. The sign shall be clearly legible and shall read as follows:

**WARNING**

PARTS OF THE CONTROLLER ARE NOT DE-ENERGIZED BY THIS SWITCH.

**(C) Interconnection Multicar Controllers.** Where interconnections between controllers are necessary for the operation of the system on multicar installations that remain energized from a source other than the one disconnected, a warning sign in accordance with 620.52(B) shall be mounted on or next to the disconnecting means.

**620.53 Car Light, Receptacle(s), and Ventilation Disconnecting Means**

Elevators shall have a single means for disconnecting all ungrounded car light, receptacle(s), and ventilation power-supply conductors for that elevator car.

The disconnecting means shall be an enclosed externally operable fused motor circuit switch or circuit breaker capable of being locked in the open position and shall be located in the machine room or control room for that elevator car. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment. Where there is no machine room or control room, the disconnecting means shall be located in a machinery space or control space outside the hoistway that is readily accessible to only qualified persons.

Section 620.53 specifies the location of the disconnecting means for lighting, receptacle, and ventilation branch circuits associated with elevators that do not have a machine room. This type of installation includes those designs using drive systems located on the car, on the counterweight, or in the hoistway. Such designs include screw drive or linear induction motor drives. See ASME A17.1-2007, *Safety Code for Elevators and Escalators*, for more information on this type of arrangement.

The means to lock the disconnecting means in the open position must be an accessory that is identified for this use and has to be in place on the disconnecting means at all times. Portable-type lockout mechanisms cannot be used to comply with this requirement. The chance that a portable-type device could easily be removed from the disconnecting

means location compromises the safety benefit of having a disconnecting means that is at all times equipped to be locked off or open.

Disconnecting means shall be numbered to correspond to the identifying number of the elevator car whose light source they control.

The disconnecting means shall be provided with a sign to identify the location of the supply side overcurrent protective device.

*Exception: Where an individual branch circuit supplies car lighting, a receptacle(s), and a ventilation motor not exceeding 2 hp, the disconnecting means required by 620.53 shall be permitted to comply with 430.109(C). This disconnecting means shall be listed and shall be capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at the disconnecting means and shall remain with the equipment.*

Section 430.109(C) permits the use of general-use snap switches and listed manual motor controllers as disconnecting means for motors rated 2 hp or less and 300 volts or less. General-use snap switches used as a disconnecting means for motors not exceeding these parameters are not required to have a horsepower rating. All of the methods permitted by this section are required to be capable of being locked in the open position using a means to accommodate the lock that cannot be removed from the switch or manual motor controller.

**620.54 Heating and Air-Conditioning Disconnecting Means**

Elevators shall have a single means for disconnecting all ungrounded car heating and air-conditioning power-supply conductors for that elevator car.

The disconnecting means shall be an enclosed externally operable fused motor circuit switch or circuit breaker capable of being locked in the open position and shall be located in the machine room or control room for that elevator car. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and

remain with the equipment. Where there is no machine room or control room, the disconnecting means shall be located in a machinery space or control space outside the hoistway that is readily accessible to only qualified persons.

Where there is equipment for more than one elevator car in the machine room, the disconnecting means shall be numbered to correspond to the identifying number of the elevator car whose heating and air-conditioning source they control.

The disconnecting means shall be provided with a sign to identify the location of the supply side overcurrent protective device.

### 620.55 Utilization Equipment Disconnecting Means

Each branch circuit for other utilization equipment shall have a single means for disconnecting all ungrounded conductors. The disconnecting means shall be capable of being locked in the open position and shall be located in the machine room or control room/machine space or control space. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment.

Where there is more than one branch circuit for other utilization equipment, the disconnecting means shall be numbered to correspond to the identifying number of the equipment served. The disconnecting means shall be provided with a sign to identify the location of the supply side overcurrent protective device.

## VII. Overcurrent Protection

### 620.61 Overcurrent Protection

Overcurrent protection shall be provided in accordance with 620.61(A) through (D).

**(A) Operating Devices and Control and Signaling Circuits.** Operating devices and control and signaling circuits shall be protected against overcurrent in accordance with the requirements of 725.43 and 725.45.

Class 2 power-limited circuits shall be protected against overcurrent in accordance with the requirements of Chapter 9, Notes to Tables 11(A) and 11(B).

**(B) Overload Protection for Motors.** Motor and branch-circuit overload protection shall conform to Article 430, Part III, and (B)(1) through (B)(4).

**(1) Duty Rating on Elevator, Dumbwaiter, and Motor-Generator Sets Driving Motors.** Duty on elevator and

dumbwaiter driving machine motors and driving motors of motor-generators used with generator field control shall be rated as intermittent. Such motors shall be permitted to be protected against overload in accordance with 430.33.

**(2) Duty Rating on Escalator Motors.** Duty on escalator and moving walk driving machine motors shall be rated as continuous. Such motors shall be protected against overload in accordance with 430.32.

**(3) Overload Protection.** Escalator and moving walk driving machine motors and driving motors of motor-generator sets shall be protected against running overload as provided in Table 430.37.

**(4) Duty Rating and Overload Protection on Platform Lift and Stairway Chairlift Motors.** Duty on platform lift and stairway chairlift driving machine motors shall be rated as intermittent. Such motors shall be permitted to be protected against overload in accordance with 430.33.

Informational Note: For further information, see 430.44 for orderly shutdown.

**(C) Motor Feeder Short-Circuit and Ground-Fault Protection.** Motor feeder short-circuit and ground-fault protection shall be as required in Article 430, Part V.

**(D) Motor Branch-Circuit Short-Circuit and Ground-Fault Protection.** Motor branch-circuit short-circuit and ground-fault protection shall be as required in Article 430, Part IV.

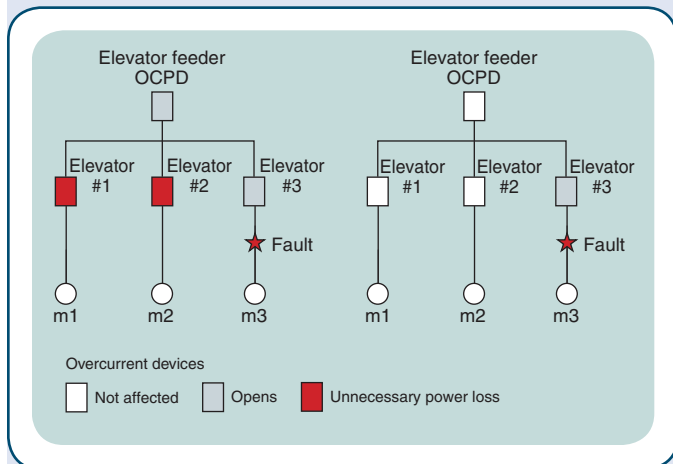

### 620.62 Selective Coordination

Where more than one driving machine disconnecting means is supplied by a single feeder, the overcurrent protective devices in each disconnecting means shall be selectively coordinated with any other supply side overcurrent protective devices.

Coordination of the overcurrent protective devices is important to ensure continuity of power where more than one elevator is supplied by a single feeder. For example, if a building contains three elevators and a fault occurs in the circuit conductors to one of the elevators, only the overcurrent device ahead of that faulted circuit should open. Coordination leaves the remaining two elevators in operation. This is especially important because elevators are commonly used to carry fire fighters and equipment closer to the fire during fire-fighting operations. Where the overcurrent devices in the elevator room do not have proper coordination with the upstream feeder overcurrent device, the potential for interruption of power to all three elevators is increased.

For selective coordination of overcurrent protective devices, the manufacturer's time-current curves, let-through and withstand capacity data, and unlatching times data must be used for sizing or setting overcurrent devices. The one-line diagram on the right side of Exhibit 620.8 illustrates the overcurrent protection arrangement required by 620.62, while the left side shows the potential for unnecessary power interruption to all of the elevators where the overcurrent protection is not selectively coordinated. Feeder overcurrent devices in the main distribution panel should not open, so two elevators can remain in use. See 620.51(A) for the requirement regarding power-supply disconnecting means.

**EXHIBIT 620.8** Examples of a system of overcurrent protective devices that are not selectively coordinated (left) and a system where selectively coordinated overcurrent protection limits the power outage to only the elevator circuit in which the fault has occurred (right).

## VIII. Machine Rooms, Control Rooms, Machinery Spaces, and Control Spaces

### 620.71 Guarding Equipment

Elevator, dumbwaiter, escalator, and moving walk driving machines; motor-generator sets; motor controllers; and disconnecting means shall be installed in a room or space set aside for that purpose unless otherwise permitted in 620.71(A) or (B). The room or space shall be secured against unauthorized access.

**(A) Motor Controllers.** Motor controllers shall be permitted outside the spaces herein specified, provided they are in enclosures with doors or removable panels that are capable of being locked in the closed position and the disconnecting means is located adjacent to or is an integral part of the motor controller. Motor controller enclosures for escalator or moving walks shall be permitted in the balustrade on the

side located away from the moving steps or moving treadway. If the disconnecting means is an integral part of the motor controller, it shall be operable without opening the enclosure.

**(B) Driving Machines.** Elevators with driving machines located on the car, on the counterweight, or in the hoistway, and driving machines for dumbwaiters, platform lifts, and stairway lifts, shall be permitted outside the spaces herein specified.

## IX. Grounding

### 620.81 Metal Raceways Attached to Cars

Metal raceways, Type MC cable, Type MI cable, or Type AC cable attached to elevator cars shall be bonded to metal parts of the car that are bonded to the equipment grounding conductor.

### 620.82 Electric Elevators

For electric elevators, the frames of all motors, elevator machines, controllers, and the metal enclosures for all electrical equipment in or on the car or in the hoistway shall be bonded in accordance with Article 250, Parts V and VII.

### 620.83 Nonelectric Elevators

For elevators other than electric having any electrical conductors attached to the car, the metal frame of the car, where normally accessible to persons, shall be bonded in accordance with Article 250, Parts V and VII.

### 620.84 Escalators, Moving Walks, Platform Lifts, and Stairway Chairlifts

Escalators, moving walks, platform lifts, and stairway chairlifts shall comply with Article 250.

### 620.85 Ground-Fault Circuit-Interrupter Protection for Personnel

Each 125-volt, single-phase, 15- and 20-ampere receptacle installed in pits, in hoistways, on elevator car tops, and in escalator and moving walk wellways shall be of the ground-fault circuit-interrupter type.

All 125-volt, single-phase, 15- and 20-ampere receptacles installed in machine rooms and machinery spaces shall have ground-fault circuit-interrupter protection for personnel.

A single receptacle supplying a permanently installed sump pump shall not require ground-fault circuit-interrupter protection.

The GFCI requirements of 620.85 are intended to reduce the shock hazard to maintenance personnel who service elevator

equipment using portable hand tools and temporary lighting.

The first paragraph of 620.85 requires a GFCI-type receptacle for each 15- and 20-ampere receptacle installed in pits, on elevator car tops, and in escalator and moving-walk wellways. This requirement is based on the premise that the reset pushbutton for a tripped GFCI receptacle should be within easy reach of an elevator mechanic working in confined spaces.

The second paragraph of 620.85 requires that all 15- and 20-ampere receptacles installed in machine rooms and machinery spaces have GFCI protection for personnel. This protection can be afforded by either a GFCI-type circuit breaker or a GFCI-type receptacle because machine spaces usually do not cause access hazards for service personnel.

## X. Emergency and Standby Power Systems

### 620.91 Emergency and Standby Power Systems

An elevator(s) shall be permitted to be powered by an emergency or standby power system.

Informational Note: See ASME A17.1-2007/CSA B44-07, *Safety Code for Elevators and Escalators*, 2.27.2, for additional information.

**(A) Regenerative Power.** For elevator systems that regenerate power back into the power source that is unable to absorb the regenerative power under overhauling elevator load conditions, a means shall be provided to absorb this power.

**(B) Other Building Loads.** Other building loads, such as power and lighting, shall be permitted as the energy absorption means required in 620.91(A), provided that such loads are automatically connected to the emergency or standby power system operating the elevators and are large enough to absorb the elevator regenerative power.

**(C) Disconnecting Means.** The disconnecting means required by 620.51 shall disconnect the elevator from both the emergency or standby power system and the normal power system.

Where an additional power source is connected to the load side of the disconnecting means, which allows automatic movement of the car to permit evacuation of passengers, the disconnecting means required in 620.51 shall be provided with an auxiliary contact that is positively opened mechanically, and the opening shall not be solely dependent on springs. This contact shall cause the additional power source to be disconnected from its load when the disconnecting means is in the open position.

### I. General

A variety of street- and highway-worthy electric and combination electric/fossil fuel or hybrid vehicles are or will soon be available to consumers. The Clean Air Act Amendments of 1990, the National Energy Policy Act of 1992, and more

recently, the National Energy Policy Act of 2005 regulate public and private purchases of clean-fuel vehicles and alternatively fueled vehicles, respectively. Electric vehicles fulfill both of those requirements. Plug-in hybrid and all-electric vehicle technology have evolved to the point that they are a viable option to the consumer. It is apparent that electric vehicle charging will be occurring in all occupancies, including residential, commercial, retail, and public sites.

Article 625 sets forth installation safety requirements for charging equipment and for connecting the charging (supply) equipment to the electric vehicle through either a conductive or inductive connection. In particular, this article covers the wiring methods, equipment construction, control and protection, and equipment locations for automotive-type vehicle charging equipment. In addition, ventilation requirements aimed at preventing an ignitable air/hydrogen mixture are included in the requirements of Article 625. The fundamental purpose of the *Code* to minimize fire and shock hazards is conveyed through the Article 625 requirements covering the charger–vehicle interface and the environment that is created by the charging of some types of batteries. The National Institute of Standards and Technology projects that in the foreseeable future, many homes and businesses will have electric vehicle charging infrastructure included as part of the premises wiring system.

### 625.1 Scope

The provisions of this article cover the electrical conductors and equipment external to an electric vehicle that connect an electric vehicle to a supply of electricity by conductive or inductive means, and the installation of equipment and devices related to electric vehicle charging.

**Informational Note:** For industrial trucks, see NFPA 505-2011, *Fire Safety Standard for Powered Industrial Trucks Including Type Designations, Areas of Use, Conversions, Maintenance, and Operation*.

The scope of Article 625 is intended to cover all electrical wiring and equipment installed between the service point and the skin of an automotive-type electric vehicle. Automotive-type electric vehicles are emphasized because they are much different from other commonly used electric vehicles, such as industrial forklifts, hoists, lifts, transports, golf carts, and airport personnel trams. The charging requirements and other exterior electrical connections for these off-road vehicles are usually serviced and maintained by trained mechanics or technicians. The *NEC* has adequate provisions to allow the authority having jurisdiction to make interpretations that provide the safety levels needed for these installations.

### 625.2 Definitions

Several of the definitions in 625.2 correlate with industry standards such as those from the Society of Automotive Engineers, SAE J1772, *SAE Electric Vehicle Conductive Charge Coupler*, and SAE J1773, *SAE Electric Vehicle Inductively Coupled Charging*; and from Underwriters Laboratories, UL 2231-1, *Standard for Personnel Protection Systems for Electric Vehicle Supply Circuits: General Requirements*, and UL 2231-2, *Standard for Personnel Protection Systems for Electric Vehicle Supply Circuits: Particular Requirements for Protection Devices for Use in Charging Systems*.

**Electric Vehicle.** An automotive-type vehicle for on-road use, such as passenger automobiles, buses, trucks, vans, neighborhood electric vehicles, electric motorcycles, and the like, primarily powered by an electric motor that draws current from a rechargeable storage battery, fuel cell, photovoltaic array, or other source of electric current. Plug-in hybrid electric vehicles (PHEV) are considered electric vehicles. For the purpose of this article, off-road, self-propelled electric vehicles, such as industrial trucks, hoists, lifts, transports, golf carts, airline ground support equipment, tractors, boats, and the like, are not included.

The primary difference between electric vehicles (EVs) as defined in Article 625 and electric vehicles covered by other sections in the *NEC* is in their road and highway worthiness. Today's automotive electric vehicles, such as the car shown in Exhibit 625.1 and the van shown in Exhibit 625.2, are comparable in performance and function to conventional automobiles and light trucks. The automotive electric vehicles under development must be capable of complying with the Federal Motor Vehicle Safety Standards and other Department of Transportation, National Highway Traffic Safety Administration, and U.S. Environmental Protection Agency requirements.

The definition of *electric vehicle* includes neighborhood electric vehicles (NEVs), which are low-speed, limited-use electric vehicles similar to golf carts but provided with automotive-grade headlights, seat belts, windshields, brakes, and other safety equipment that makes them street legal. Neighborhood electric vehicles are increasing in popularity as low-cost, energy-efficient, zero-polluting alternatives to traditional automobiles. Under National Highway Traffic Safety Administration guidelines, the intended use for these vehicles is shopping and recreation in inner-city areas and planned and retirement communities where the street speed limit is 35 mph or less. Electric vehicles such as lift trucks and golf carts are not covered by Article 625.

**EXHIBIT 625.1** Chevrolet Volt, an example of the latest technology in electric vehicles.

Today's electric vehicles can also be used as a power source for an optional standby system as covered in Article 702 or as an electric power production source as covered in Article 705. The *electric vehicle supply equipment* can either transfer power from the premises to the electric vehicle or from the electric vehicle to the premises wiring system through an interactive system covered in 625.26.

**Electric Vehicle Connector.** A device that, by insertion into an electric vehicle inlet, establishes an electrical connection to the electric vehicle for the purpose of **power transfer** and information exchange. This device is part of the electric vehicle coupler.

**Informational Note:** For further information, see 625.26 for interactive systems.

**Electric Vehicle Coupler.** A mating electric vehicle inlet and electric vehicle connector set.

**Electric Vehicle Inlet.** The device on the electric vehicle into which the electric vehicle connector is inserted for **power transfer** and information exchange. This device is part of the electric vehicle coupler. For the purposes of this *Code*, the electric vehicle inlet is considered to be part of the electric vehicle and not part of the electric vehicle supply equipment.

**Informational Note:** For further information, see 625.26 for interactive systems.

**Electric Vehicle Nonvented Storage Battery.** A hermetically sealed battery, comprised of one or more rechargeable electrochemical cells, that has no provision for the release

**EXHIBIT 625.2** Electric van connected to electric vehicle supply equipment.

of excessive gas pressure, or for the addition of water or electrolyte, or for external measurements of electrolyte specific gravity.

**Electric Vehicle Supply Equipment.** The conductors, including the ungrounded, grounded, and equipment grounding conductors and the electric vehicle connectors, attachment plugs, and all other fittings, devices, power outlets, or apparatus installed specifically for the purpose of transferring energy between the premises wiring and the electric vehicle.

Electric vehicle supply equipment, as illustrated in Exhibit 625.3, comprises the components between the skin of the electric vehicle and the premises wiring, including any flexible cable, disconnecting means, enclosures, power outlet, and electric vehicle connector. The definition of *electric vehicle* includes all off-vehicle charging equipment and does not include charging equipment installed on the vehicle.

**EXHIBIT 625.3** Parking space equipped with electric vehicle supply equipment. (Courtesy of the International Association of Electrical Inspectors)

Informational Note: For further information, see 625.26 for interactive systems.

**Personnel Protection System.** A system of personnel protection devices and constructional features that when used

together provide protection against electric shock of personnel.

**Plug-In Hybrid Electric Vehicle (PHEV).** A type of electric vehicle intended for on-road use with the ability to store and use off-vehicle electrical energy in the rechargeable energy storage system, and having a second source of motive power.

A *plug-in hybrid electric vehicle* can be charged through either its own rechargeable energy storage system or through connection to electric vehicle supply equipment located at a home, business or other location.

**Rechargeable Energy Storage System.** Any power source that has the capability to be charged and discharged.

Informational Note: Batteries, capacitors, and electromechanical flywheels are examples of rechargeable energy storage systems.

## 625.4 Voltages

Unless other voltages are specified, the nominal ac system voltages of 120, 120/240, 208Y/120, 240, 480Y/277, 480, 600Y/347, and 600 volts shall be used to supply equipment covered by this article.

## 625.5 Listed or Labeled

All electrical materials, devices, fittings, and associated equipment shall be listed or labeled.

# II. Wiring Methods

## 625.9 Electric Vehicle Coupler

The electric vehicle coupler shall comply with 625.9(A) through (F).

The electric vehicle connector is the device that inserts into the electric vehicle inlet (charge port) of the vehicle. The electric vehicle inlet is not a premises wiring receptacle or an attachment cap. An electric vehicle coupler is the mating set of the electric vehicle connector and electric vehicle inlet. The coupler is required to be noninterchangeable to prevent equipment damage or personal injury, and it is not permitted to be a standard NEMA-configuration wiring device.

**(A) Polarization.** The electric vehicle coupler shall be polarized unless part of a system identified and listed as suitable for the purpose.

**(B) Noninterchangeability.** The electric vehicle coupler shall have a configuration that is noninterchangeable with

wiring devices in other electrical systems. Nongrounding-type electric vehicle couplers shall not be interchangeable with grounding-type electric vehicle couplers.

**(C) Construction and Installation.** The electric vehicle coupler shall be constructed and installed so as to guard against inadvertent contact by persons with parts made live from the electric vehicle supply equipment or the electric vehicle battery.

The requirements for coupler construction in 625.9(C) provide a safe interface component for persons connecting the vehicle to or disconnecting the vehicle from the charging system. This type of activity generally is performed by persons who typically do not have any knowledge of the equipment operation and its associated hazards.

**(D) Unintentional Disconnection.** The electric vehicle coupler shall be provided with a positive means to prevent unintentional disconnection.

**(E) Grounding Pole.** The electric vehicle coupler shall be provided with a grounding pole, unless part of a system identified and listed as suitable for the purpose in accordance with Article 250.

**(F) Grounding Pole Requirements.** If a grounding pole is provided, the electric vehicle coupler shall be so designed that the grounding pole connection is the first to make and the last to break contact.

### III. Equipment Construction

#### 625.13 Electric Vehicle Supply Equipment

Electric vehicle supply equipment rated at 125 volts, single phase, 15 or 20 amperes or part of a system identified and listed as suitable for the purpose and meeting the requirements of 625.18, 625.19, and 625.29 shall be permitted to be cord-and-plug-connected. All other electric vehicle supply equipment shall be permanently connected and fastened in place. This equipment shall have no exposed live parts.

Some manufacturers produce 125-volt, single-phase, 15- or 20-ampere portable charging units for convenience charging. These charging units may be stored in the vehicle. However, 625.13 makes it clear that non-portable equipment must be mounted and permanently wired. This equipment may be physically attached to the wall, floor, or ceiling. The provision for no exposed live parts is a safety concern for the general public.

#### 625.14 Rating

Electric vehicle supply equipment shall have sufficient rating to supply the load served. For the purposes of this article, electric vehicle charging loads shall be considered to be continuous loads.

Considering both near-term and long-term requirements for electric vehicle (EV) charging, three methods have been identified for recommended development. Referred to as Level 1, Level 2, and Level 3 EV charging, they cover the range of power levels anticipated for charging EVs.

**Level 1.** This method, which allows broad access to charge an EV, permits plugging into a common, grounded 120-volt electrical receptacle (NEMA 5-15R or 5-20R). The maximum load on this receptacle is 12 amperes or 1.4 kVA. The minimum circuit and overcurrent rating for this connection is 15 amperes for a 15-ampere receptacle and 20 amperes for a 20-ampere receptacle.

**Level 2.** This level is the primary and preferred method of EV charging at both private and public facilities. It requires special equipment and connection to an electric power supply dedicated to EV charging. The voltage of this connection is either 240 volts or 208 volts. The maximum load is 32 amperes (7.7 kVA at 240 volts or 6.7 kVA at 208 volts). The minimum circuit and overcurrent rating for this connection is 40 amperes ( $32 \times 1.25 = 40$  amperes). Electric vehicles are treated as continuous loads. See 625.21 for sizing overcurrent protection devices.

**Level 3.** The EV equivalent of a commercial gasoline dispensing station, this high-speed, high-power method charges an EV in about the same time it takes to refuel a conventional vehicle. Because of individual supply requirements and available source voltages, exact voltage and load specifications for Level 3 charging have not been defined as in Level 1 and Level 2. These power requirements are specified by the equipment manufacturer.

#### 625.15 Markings

The electric vehicle supply equipment shall comply with 625.15(A) through (C).

**(A) General.** All electric vehicle supply equipment shall be marked by the manufacturer as follows:

##### FOR USE WITH ELECTRIC VEHICLES

**(B) Ventilation Not Required.** Where marking is required by 625.29(C), the electric vehicle supply equipment shall be clearly marked by the manufacturer as follows:

##### VENTILATION NOT REQUIRED

The marking shall be located so as to be clearly visible after installation.

(C) **Ventilation Required.** Where marking is required by 625.29(D), the electric vehicle supply equipment shall be clearly marked by the manufacturer, “Ventilation Required.” The marking shall be located so as to be clearly visible after installation.

### 625.16 Means of Coupling

The means of coupling to the electric vehicle shall be either conductive or inductive. Attachment plugs, electric vehicle connectors, and electric vehicle inlets shall be listed or labeled for the purpose.

### 625.17 Cable

The electric vehicle supply equipment cable shall be Type EV, EVJ, EVE, EVJE, EVT, or EVJT flexible cable as specified in Article 400 and Table 400.4. Ampacities shall be as specified in Table 400.5(A)(1) for 10 AWG and smaller, and in Table 400.5(A)(2) for 8 AWG and larger. The overall length of the cable shall not exceed 7.5 m (25 ft) unless equipped with a cable management system that is listed as suitable for the purpose. Other cable types and assemblies listed as being suitable for the purpose, including optional hybrid communications, signal, and composite optical fiber cables, shall be permitted.

The maximum 25-ft cable length required by 625.17 takes into account a 15-ft car length, a 7-ft car width, and a 3-ft length to the power outlet securement point. This requirement limits excessive cable lengths, which may be exposed to damage. Cable lengths in excess of 25 ft are permitted where provided with a listed cable management system, which provides flexibility for commercial parking areas in terms of the number of charging spaces provided.

### 625.18 Interlock

Electric vehicle supply equipment shall be provided with an interlock that de-energizes the electric vehicle connector and its cable whenever the electrical connector is uncoupled from the electric vehicle. An interlock shall not be required for portable cord-and-plug-connected electric vehicle supply equipment intended for connection to receptacle outlets rated at 125 volts, single phase, 15 and 20 amperes.

To reduce shock hazard, a pilot or communications interlock establishes power through the electric vehicle supply equipment. Loss of the pilot or communications circuit locks out power, isolating possible hazardous situations in the electric vehicle supply equipment. See 625.29(D) for mechanical ventilation interlock requirements. For ventilation interlock, see 625.29(D)(3) for 125-volt receptacles intended to charge electric vehicles.

### 625.19 Automatic De-Energization of Cable

The electric vehicle supply equipment or the cable-connector combination of the equipment shall be provided with an automatic means to de-energize the cable conductors and electric vehicle connector upon exposure to strain that could result in either cable rupture or separation of the cable from the electric connector and exposure of live parts. Automatic means to de-energize the cable conductors and electric vehicle connector shall not be required for portable cord-and-plug-connected electric vehicle supply equipment intended for connection to receptacle outlets rated at 125 volts, single phase, 15 and 20 amperes.

## IV. Control and Protection

### 625.21 Overcurrent Protection

Overcurrent protection for feeders and branch circuits supplying electric vehicle supply equipment shall be sized for continuous duty and shall have a rating of not less than 125 percent of the maximum load of the electric vehicle supply equipment. Where noncontinuous loads are supplied from the same feeder or branch circuit, the overcurrent device shall have a rating of not less than the sum of the noncontinuous loads plus 125 percent of the continuous loads.

### 625.22 Personnel Protection System

The electric vehicle supply equipment shall have a listed system of protection against electric shock of personnel. The personnel protection system shall be composed of listed personnel protection devices and constructional features. Where cord-and-plug-connected electric vehicle supply equipment is used, the interrupting device of a listed personnel protection system shall be provided and shall be an integral part of the attachment plug or shall be located in the power supply cable not more than 300 mm (12 in.) from the attachment plug.

The personnel protection system may consist of one or more components that provide protection against electric shock for different portions of the electric vehicle supply equipment circuitry, which may be operating at frequencies other than 50/60 Hz, at direct-current potentials, and/or voltages above 150 volts to ground. Standard GFCI devices do not provide the range of protection needed for the various types of charging systems being developed. Devices or methods that may be used include basic insulation, double insulation, grounding monitors, insulation monitors with interrupters, and leakage current monitors. Many combinations and variations of these devices can be used to provide the personnel protection required. For systems operating above 150 volts to ground, the protective system may include monitoring systems to ensure that proper grounding is provided and maintained during charging.

### 625.23 Disconnecting Means

For electric vehicle supply equipment rated more than 60 amperes or more than 150 volts to ground, the disconnecting means shall be provided and installed in a readily accessible location. The disconnecting means shall be capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted.

### 625.25 Loss of Primary Source

Means shall be provided such that, upon loss of voltage from the utility or other electrical system(s), energy cannot be back fed through the electric vehicle and the supply equipment to the premises wiring system unless permitted by 625.26.

### 625.26 Interactive Systems

Electric vehicle supply equipment and other parts of a system, either on-board or off-board the vehicle, that are identified for and intended to be interconnected to a vehicle and also serve as an optional standby system or an electric power production source or provide for bi-directional power feed shall be listed as suitable for that purpose. When used as an optional standby system, the requirements of Article 702 shall apply, and when used as an electric power production source, the requirements of Article 705 shall apply.

The on-board power production system of some electric vehicles is capable of operating as a stand-alone or interactive power supply for premises wiring systems. Such systems are required to be listed for this type of use, and 625.26 requires compliance with the requirements of Article 702 or Article 705, depending on how the system connects to premises wiring system and/or the primary source of electricity.

## V. Electric Vehicle Supply Equipment Locations

### 625.28 Hazardous (Classified) Locations

Where electric vehicle supply equipment or wiring is installed in a hazardous (classified) location, the requirements of Articles 500 through 516 shall apply.

The installation of EV charging equipment is permitted in hazardous locations where the installation is made in accordance with the requirements of Chapter 5. The increased use of electric vehicles makes this provision necessary to cover

installations at commercial repair garages and combination gasoline/EV charging stations (see 511.10).

### 625.29 Indoor Sites

Indoor sites shall include, but not be limited to, integral, attached, and detached residential garages; enclosed and underground parking structures; repair and nonrepair commercial garages; and agricultural buildings.

**(A) Location.** The electric vehicle supply equipment shall be located to permit direct connection to the electric vehicle.

**(B) Height.** Unless specifically listed for the purpose and location, the coupling means of the electric vehicle supply equipment shall be stored or located at a height of not less than 450 mm (18 in.) and not more than 1.2 m (4 ft) above the floor level.

**(C) Ventilation Not Required.** Where electric vehicle nonvented storage batteries are used or where the electric vehicle supply equipment is listed or labeled as suitable for charging electric vehicles indoors without ventilation and marked in accordance with 625.15(B), mechanical ventilation shall not be required.

Major auto manufacturers are taking the necessary steps to make electric vehicle systems safe. Most batteries used in electric vehicles manufactured by major automakers do not emit hydrogen gas in quantities that could cause an explosion. Preventive measures such as mechanical or passive ventilation are not required, because the electric vehicle batteries and charging systems are designed to prevent or limit the emission of hydrogen during charging. The Society of Automotive Engineers recommended practice SAE J-1718, *Measurement of Hydrogen Gas Emission from Battery-Powered Passenger Cars and Light Trucks During Battery Charging*, can be used to assess suitability for indoor charging. This standard includes provisions for tests during normal charging operations and potential equipment failure modes.

**(D) Ventilation Required.** Where the electric vehicle supply equipment is listed or labeled as suitable for charging electric vehicles that require ventilation for indoor charging, and is marked in accordance with 625.15(C), mechanical ventilation, such as a fan, shall be provided. The ventilation shall include both supply and exhaust equipment and shall be permanently installed and located to intake from, and vent directly to, the outdoors. Positive pressure ventilation systems shall be permitted only in buildings or areas that have been specifically designed and approved for that

application. Mechanical ventilation requirements shall be determined by one of the methods specified in 625.29(D)(1) through (D)(4).

The interlock described in 625.29(D) prevents a vehicle requiring ventilation from being charged unless ventilation is provided. This interlock feature is included in the pilot connection of the standard electric vehicle supply equipment connection.

**(1) Table Values.** For supply voltages and currents specified in Table 625.29(D)(1) or Table 625.29(D)(2), the minimum ventilation requirements shall be as specified in Table 625.29(D)(1) or Table 625.29(D)(2) for each of the total number of electric vehicles that can be charged at one time.

**(2) Other Values.** For supply voltages and currents other than specified in Table 625.29(D)(1) or Table 625.29(D)(2), the minimum ventilation requirements shall be calculated by means of the following general formulas, as applicable:

(1) Single phase: Ventilation<sub>single phase</sub> in cubic meters per minute (m<sup>3</sup>/min) =

$$\frac{(\text{volts})(\text{amperes})}{1718}$$

Ventilation<sub>single phase</sub> in cubic feet per minute (cfm) =

$$\frac{(\text{volts})(\text{amperes})}{48.7}$$

(2) Three phase: Ventilation<sub>three phase</sub> in cubic meters per minute (m<sup>3</sup>/min) =

$$\frac{1.732(\text{volts})(\text{amperes})}{1718}$$

Ventilation<sub>three phase</sub> in cubic feet per minute (cfm) =

$$\frac{1.732(\text{volts})(\text{amperes})}{48.7}$$

**(3) Engineered Systems.** For an electric vehicle supply equipment ventilation system designed by a person qualified to perform such calculations as an integral part of a building’s total ventilation system, the minimum ventilation requirements shall be permitted to be determined in accordance with calculations specified in the engineering study.

**(4) Supply Circuits.** The supply circuit to the mechanical ventilation equipment shall be electrically interlocked with the electric vehicle supply equipment and shall remain energized during the entire electric vehicle charging cycle. Electric vehicle supply equipment shall be marked in accordance with 625.15. Electric vehicle supply equipment receptacles rated at 125 volts, single phase, 15 and 20 amperes shall be marked in accordance with 625.15(C) and shall be switched, and the mechanical ventilation system shall be electrically interlocked through the switch supply power to the receptacle.

The intent of 625.29(D) is to ensure sufficient diffusion and dilution of hydrogen gas from gas-emitting batteries to pre-

**TABLE 625.29(D)(1) Minimum Ventilation Required in Cubic Meters per Minute (m<sup>3</sup>/min) for Each of the Total Number of Electric Vehicles That Can Be Charged at One Time**

vent a hazardous condition. During the charging process, certain batteries used in some electric vehicles emit hydrogen gas, which is colorless, odorless, tasteless, nontoxic, and flammable. At atmospheric pressure, the flammable range for hydrogen is 4 to 75 percent by volume in air.

NFPA 69, *Standard on Explosion Prevention Systems*, establishes requirements to ensure safety with flammable mixtures. The provisions of Section 7.3, Design and Operating Requirements, of NFPA 69-2008 specify that combustible gas concentrations be restricted to 25 percent of the lower flammable limit. This design criterion provides a safety margin for personnel working with atmospheres containing hydrogen. Safety is accomplished by keeping the concentration of hydrogen below 25 percent of the lower flammability limit, or 1 percent (25 percent  $\times$  4 percent = 1 percent) hydrogen by volume in air, that is, below 10,000 ppm hydrogen.

A ventilation system for a typical residential-type garage includes both supply and mechanical exhaust equipment and is permanently installed. The equipment is located in the space such that it takes in air from outdoors to the space, circulates the air through the space, and exhausts the air directly to the outdoors. Typically, the equipment includes a passive vent for intake on one side of the enclosed space and an exhaust fan vented to the outside on the other side of the space.

In enclosed commercial garages and other structures, additional ventilation is not required if the exhaust, as required by the building code for carbon monoxide or other purposes,

is greater than the quantity listed in the table. Other engineered electric vehicle ventilation systems are allowed, provided they are designed properly. The electric vehicle charging area is permitted to be ventilated by the building ventilation system. The ventilation system and the charging system must be interlocked to prevent charging if the ventilation is not operating. This charging arrangement can be used with electric vehicles equipped with a self-contained charging system in which activation of the charging system does not depend on a signal from the electric vehicle. A manually operated switch controls the receptacle used to supply the vehicle charging system, and it is also interlocked with the power supply to the ventilation fan. This arrangement ensures that the ventilation fan is operating whenever the vehicle charging receptacle is energized. A qualified person must perform the calculation of the ventilation requirements.

### 625.30 Outdoor Sites

Outdoor sites shall include but not be limited to residential carports and driveways, curbside, open parking structures, parking lots, and commercial charging facilities.

Where the electric vehicle charging operation is conducted in outdoor or open locations, the resulting off-gassing of hydrogen does not pose the same risk of creating an ignitable environment compared to indoor locations. The lighter-than-air hydrogen readily diffuses into the atmosphere. In

addition to driveways and parking lots, structures with adequate natural ventilation, such as carports and open parking structures, do not require mechanical ventilation. NFPA 88A, *Standard for Parking Structures*, provides a quantifiable definition of the term *open parking structure*.

**(A) Location.** The electric vehicle supply equipment shall be located to permit direct connection to the electric vehicle.

**(B) Height.** Unless specifically listed for the purpose and location, the coupling means of electric vehicle supply equipment shall be stored or located at a height of not less than 600 mm (24 in.) and not more than 1.2 m (4 ft) above the parking surface.

#### I. General

##### 626.1 Scope

The provisions of this article cover the electrical conductors and equipment external to the truck or transport refrigerated unit that connect trucks or transport refrigerated units to a supply of electricity, and the installation of equipment and devices related to electrical installations within an electrified truck parking space.

As more stringent federal and state mandates to reduce diesel engine emissions are enacted into law, there is a call for electric power to allow for operation of transport truck heating and refrigeration equipment while the truck is parked. Because much of the transport industry is interstate commerce, this article provides for standardization of truck parking space equipment so that driver interface with electrical connection devices can be safely accomplished from coast to coast.

##### 626.2 Definitions

**Cable Management System.** An apparatus designed to control and organize unused lengths of cable or cord at electrified truck parking spaces.

**Cord Connector.** A device that, by inserting it into a truck flanged surface inlet, establishes an electrical connection to the truck for the purpose of providing power for the on-board electric loads and may provide a means for information exchange. This device is part of the truck coupler.

**Disconnecting Means, Parking Space.** The necessary equipment usually consisting of a circuit breaker or switch and fuses, and their accessories, located near the point of entrance of supply conductors in an electrified truck parking space and intended to constitute the means of cutoff for the supply to that truck.

**Electrified Truck Parking Space.** A truck parking space that has been provided with an electrical system that allows truck operators to connect their vehicles while stopped and to use off-board power sources in order to operate on-board systems such as air conditioning, heating, and appliances, without any engine idling.

Informational Note: An electrified truck parking space also includes dedicated parking areas for heavy-duty trucks at travel plazas, warehouses, shipper and consignee yards, depot facilities, and border crossings. It does not include areas such as the shoulders of highway ramps and access roads, camping and recreational vehicle sites, residential and commercial parking areas used for automotive parking or other areas where ac power is provided solely for the purpose of connecting automotive and other light electrical loads, such as engine block heaters, and at private residences.

**Electrified Truck Parking Space Wiring Systems.** All of the electrical wiring, equipment, and appurtenances related to electrical installations within an electrified truck parking space, including the electrified parking space supply equipment.

**Overhead Gantry.** A structure consisting of horizontal framework, supported by vertical columns spanning above electrified truck parking spaces, that supports equipment, appliances, raceway, and other necessary components for the purpose of supplying electrical, HVAC, internet, communications, and other services to the spaces.

**Separable Power Supply Cable Assembly.** A flexible cord or cable, including ungrounded, grounded, and equipment grounding conductors, provided with a cord connector, an attachment plug, and all other fittings, grommets, or devices installed for the purpose of delivering energy from the source of electrical supply to the truck or TRU flanged surface inlet.

**Transport Refrigerated Unit (TRU).** A trailer or container, with integrated cooling or heating, or both, used for the purpose of maintaining the desired environment of temperature-sensitive goods or products.

**Truck.** A motor vehicle designed for the transportation of goods, services, and equipment.

**Truck Coupler.** A truck flanged surface inlet and mating cord connector.

**Truck Flanged Surface Inlet.** The device(s) on the truck into which the connector(s) is inserted to provide electric energy and other services. This device is part of the truck coupler. For the purposes of this article, the truck flanged surface inlet is considered to be part of the truck and not part of the electrified truck parking space supply equipment.

### 626.3 Other Articles

Wherever the requirements of other articles of this *Code* and Article 626 differ, the requirements of Article 626 shall apply. Unless electrified truck parking space wiring systems are supported or arranged in such a manner that they cannot be used in or above locations classified in 511.3 or 514.3, or both, they shall comply with 626.3(A) and (B) in addition to the requirements of this article.

**(A) Vehicle Repair and Storage Facilities.** Electrified truck parking space electrical wiring systems located at facilities for the repair or storage of self-propelled vehicles that use volatile flammable liquids or flammable gases for fuel or power shall comply with Article 511.

**(B) Motor Fuel Dispensing Stations.** Electrified truck parking space electrical wiring systems located at or serving motor fuel dispensing stations shall comply with Article 514.

Informational Note: For additional information, see NFPA 88A-2011, *Standard for Parking Structures*, and NFPA 30A-2008, *Code for Fuel Dispensing Facilities and Repair Garages*.

### 626.4 General Requirements

**(A) Not Covered.** The provisions of this article shall not apply to that portion of other equipment in residential, commercial, or industrial facilities that requires electric power used to load and unload cargo, operate conveyors, and for other equipment used on the site or truck.

**(B) Distribution System Voltages.** Unless other voltages are specified, the nominal ac system voltages of 120, 120/240, 208Y/120, 240, or 480Y/277 shall be used to supply equipment covered by this article.

**(C) Connection to Wiring System.** The provisions of this article shall apply to the electrified truck parking space supply equipment intended for connection to a wiring system as defined in 626.4(B).

## II. Electrified Truck Parking Space Electrical Wiring Systems

### 626.10 Branch Circuits

Electrified truck parking space single-phase branch circuits shall be derived from a 208Y/120-volt, 3-phase, 4-wire system or a 120/240-volt, single-phase, 3-wire system.

*Exception: A 120-volt distribution system shall be permitted to supply existing electrified truck parking spaces.*

### 626.11 Feeder and Service Load Calculations

**(A) Parking Space Load.** The calculated load of a feeder or service shall be not less than the sum of the loads on the branch circuits. Electrical service and feeders shall be calculated on the basis of not less than 11 kVA per electrified truck parking space.

**(B) Demand Factors.** Electrified truck parking space electrical wiring system demand factors shall be based upon the climatic temperature zone in which the equipment is installed. The demand factors set forth in Table 626.11(B)

**TABLE 626.11(B) Demand Factors for Services and Feeders**

Climatic Temperature Zone (USDA Hardiness Zone) See Note	Demand Factor (%)
1	70%
2a	67%
2b	62%
3a	59%
3b	57%
4a	55%
4b	51%
5a	47%
5b	43%
6a	39%
6b	34%
7a	29%
7b	24%
8a	21%
8b	20%
9a	20%
9b	20%
10a	21%
10b	23%
11	24%

Note: The climatic temperature zones shown in Table 626.11(B) correlate with those found on the “USDA Plant Hardiness Zone Map,” and the climatic temperature zone selected for use with the table shall be determined through the use of this map based on the installation location.

shall be the minimum allowable demand factors that shall be permitted for calculating load for service and feeders. No demand factor shall be allowed for any other load, except as provided in this article.

Informational Note: The U.S. Department of Agriculture (USDA) has developed a commonly used “Plant Hardiness Zone” map that is publicly available. The map provides guidance for determining the Climatic Temperature Zone. Data indicate that the HVAC has the highest power requirement in cold climates, with the heating demand representing the greatest load, which in turn is dependent on outside temperature. In very warm climates, where no heating load is necessary, the cooling load increases as the outdoor temperature rises.

### (C) Two or More Electrified Truck Parking Spaces.

Where the electrified truck parking space wiring system is in a location that serves two or more electrified truck parking spaces, the equipment for each space shall comply with 626.11(A), and the calculated load shall be **calculated** on the basis of each parking space.

**(D) Conductor Rating.** Truck space branch-circuit **supplied** loads shall be considered to be continuous.

## III. Electrified Truck Parking Space Supply Equipment

### 626.22 Wiring Methods and Materials

**(A) Electrified Truck Parking Space Supply Equipment Type.** The electrified truck parking space supply equipment shall be provided in one of the following forms:

- (1) Pedestal
- (2) Overhead gantry
- (3) Raised concrete pad

**(B) Mounting Height.** Post, pedestal, and raised concrete pad types of electrified truck parking space supply equipment shall be not less than 600 mm (2 ft) aboveground or above the point identified as the prevailing highest water level mark or an equivalent benchmark based on seasonal or storm-driven flooding from the authority having jurisdiction.

**(C) Access to Working Space.** All electrified truck parking space supply equipment shall be accessible by an unobstructed entrance or passageway not less than 600 mm (2 ft) wide and not **less** than 2.0 m (6 ft 6 in.) high.

**(D) Disconnecting Means.** A disconnecting switch or circuit breaker shall be provided to disconnect one or more electrified truck parking space supply equipment sites from a remote location. The disconnecting means shall be provided and installed in a readily accessible location and shall be capable of being locked in the open position. Portable

means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment.

### 626.23 Overhead Gantry or Cable Management System

**(A) Cable Management.** Electrified truck parking space equipment provided from either overhead gantry or cable management systems shall utilize a permanently attached power supply cable in electrified truck parking space supply equipment. Other cable types and assemblies listed as being suitable for the purpose, including optional hybrid communications, signal, and **composite** optical fiber cables, shall be permitted.

**(B) Strain Relief.** Means to prevent strain from being transmitted to the wiring terminals shall be provided. Permanently attached power supply cable(s) shall be provided with a means to de-energize the cable conductors and power service delivery device upon exposure to strain that could result in either cable damage or separation from the power service delivery device and exposure of live parts.

### 626.24 Electrified Truck Parking Space Supply Equipment Connection Means

**(A) General.** Each truck shall be supplied from electrified truck parking space supply equipment through suitable extra-hard service cables or cords. Each connection to the equipment shall be by a single separable power supply cable assembly.

**(B) Receptacle.** All receptacles shall be listed and of the grounding type. Every truck parking space with electrical supply shall be equipped with (B)(1) and (B)(2).

- (1) A maximum of three receptacles, each 2-pole, 3-wire grounding type and rated 20 amperes, 125 volts, and two of the three connected to two separate branch circuits.

Informational Note: For the nonlocking-type and grounding-type 20-ampere receptacle configuration, see ANSI/NEMA WD6-2002, *Standard for Dimensions of Attachment Plugs and Receptacles*, Figure 5-20.

- (2) One single receptacle, 3-pole, 4-wire grounding type, single phase rated either 30 amperes 208Y/120 volts or 125/250 volts. The 125/250-volt receptacle shall be permitted to be used on a 208Y/120-volt, single-phase circuit.

Informational Note: For various configurations of 30-ampere pin and sleeve receptacles, see ANSI/UL1686, *Standard for Pin and Sleeve Configurations*, Figure C2.9 or Part C3.

*Exception: Where electrified truck parking space supply equipment provides the heating, air-conditioning, and com-*

*fort-cooling function without requiring a direct electrical connection at the truck, only the two receptacles identified in 626.24(B)(1) shall be required.*

**(C) Disconnecting Means, Parking Space.** The electrified truck parking space supply equipment shall be provided with a switch or circuit breaker for disconnecting the power supply to the electrified truck parking space. A disconnecting means shall be provided and installed in a readily accessible location and shall be capable of being locked in the open position. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment.

**(D) Ground-Fault Circuit-Interrupter Protection for Personnel.** The electrified truck parking space equipment shall be designed and constructed such that all receptacle outlets in 626.24 are provided with ground-fault circuit-interrupter protection for personnel.

### 626.25 Separable Power-Supply Cable Assembly

A separable power-supply cable assembly, consisting of a power-supply cord, a cord connector, and an attachment plug intended for connection with a truck flanged surface inlet, shall be of a listed type. The power-supply cable assembly or assemblies shall be identified and be one of the types and ratings specified in 626.25(A) and (B). Cords with adapters and pigtail ends, extension cords, and similar items shall not be used.

**(A) Rating(s).**

**(1) Twenty-Ampere Power-Supply Cable Assembly.** Equipment with a 20-ampere, 125-volt receptacle, in accordance with 626.24(B)(1), shall use a listed 20-ampere power-supply cable assembly.

*Exception: It shall be permitted to use a listed separable power-supply cable assembly, either hard service or extra-hard service and rated 15 amperes, 125 volts, for connection to an engine block heater for legacy vehicles.*

**(2) Thirty-Ampere Power-Supply Cable Assembly.** Equipment with a 30-ampere, 208Y/120-volt or 125/250-volt receptacle, in accordance with 626.24(B)(2), shall use a listed 30-ampere main power-supply cable assembly.

**(B) Power-Supply Cord.**

**(1) Conductors.** The cord shall be a listed type with three or four conductors, for single-phase connection, one conductor of which shall be identified in accordance with 400.23.

*Exception: It shall be permitted to use a separate listed three-conductor separable power-supply cable assembly, one conductor of which shall be identified in accordance with 400.23 and rated 15 amperes, 125 volts for connection to an engine block heater for existing vehicles.*

**(2) Cord.** Extra-hard usage flexible cords and cables rated not less than 90°C (194°F), 600 volts; listed for both wet locations and sunlight resistance; and having an outer jacket rated to be resistant to temperature extremes, oil, gasoline, ozone, abrasion, acids, and chemicals shall be permitted where flexibility is necessary between the electrified truck parking space supply equipment, the panel board and flanged surface inlet(s) on the truck.

*Exception: Cords for the separable power supply cable assembly for 15- and 20-ampere connections shall be permitted to be a hard service type.*

**(3) Cord Overall Length.** The exposed cord length shall be measured from the face of the attachment plug to the point of entrance to the truck or the face of the flanged surface inlet or to the point where the cord enters the truck. The overall length of the cable shall not exceed 7.5 m (25 ft) unless equipped with a cable management system that is listed as suitable for the purpose.

**(4) Attachment Plug.** The attachment plug(s) shall be listed, by itself or as part of a cord set, for the purpose and shall be molded to or installed on the flexible cord so that it is secured tightly to the cord at the point where the cord enters the attachment plug. If a right-angle cap is used, the configuration shall be oriented so that the grounding member is farthest from the cord. Where a flexible cord is provided, the attachment plug shall comply with 250.138(A).

(a) *Connection to a 20-Ampere Receptacle.* A separable power-supply cable assembly for connection to a truck flanged surface inlet, rated at 20 amperes, shall have a nonlocking-type attachment plug that shall be 2-pole, 3-wire grounding type rated 20 amperes, 125 volts and intended for use with the 20-ampere, 125-volt receptacle.

*Exception: A separable power-supply cable assembly, rated 15 amperes, provided for the connection of an engine block heater, only, shall have an attachment plug that shall be 2-pole, 3-wire grounding type rated 15 amperes, 125 volts.*

Informational Note: For nonlocking- and grounding-type 15- or 20-ampere plug and receptacle configurations, see ANSI/NEMA WD6-2002, *Standard for Dimensions of Attachment Plugs and Receptacles*, Figure 5-15 or 5-20.

(b) *Connection to a 30-Ampere Receptacle.* A separable power-supply cable assembly for connection to a truck flanged surface inlet, rated at 30 amperes, shall have an attachment plug that shall be 3-pole, 4-wire grounding type rated 30-amperes, 208Y/120 volts or 125/250 volts, and intended for use with the receptacle in accordance with 626.24(B)(2). The 125/250-volt attachment plug shall be permitted to be used on a 208Y/120-volt, single-phase circuit.

Informational Note: For various configurations of 30-ampere pin and sleeve plugs, see ANSttI/UL1686, *Standard for Pin and Sleeve Configurations*, Figure C2.10 or Part C3.

**(5) Cord Connector.** The cord connector for a separable power-supply cable assembly, as specified in 626.25(A)(1), shall be a 2-pole, 3-wire grounding type rated 20 amperes, 125 volts. The cord connector for a separable power-supply cable assembly, as specified in 626.25(A)(2), shall be a 3-pole, 4-wire grounding type rated 30 amperes, 208Y/120 volts or 125/250 volts. The 125/250-volt cord connector shall be permitted to be used on a 208Y/120-volt, single-phase circuit.

*Exception: The cord connector for a separable power supply cable assembly, rated 15 amperes, provided for the connection of an engine block heater for existing vehicles, shall have an attachment plug that shall be 2-pole, 3-wire grounding type rated 15 amperes, 125 volts.*

Informational Note: For various configurations of 30-ampere cord connectors, see ANSI/UL1686 *Standard for Pin and Sleeve Configurations*, Figure C2.9 or Part C3.

## 626.26 Loss of Primary Power

Means shall be provided such that, upon loss of voltage from the utility or other electric supply system(s), energy cannot be back-fed through the truck and the truck supply equipment to the electrified truck parking space wiring system unless permitted by 626.27.

## 626.27 Interactive Systems

Electrified truck parking space supply equipment and other parts of a system, either on-board or off-board the vehicle, that are identified for and intended to be interconnected to a vehicle and also serve as an optional standby system or an electric power production source or provide for bi-directional power feed shall be listed as suitable for that purpose. When used as an optional standby system, the requirements of Article 702 shall apply, and when used as an electric power production source, the requirements of Article 705 shall apply.

## IV. Transport Refrigerated Units (TRUs)

### 626.30 Transport Refrigerated Units

Electrified truck parking spaces intended to supply transport refrigerated units (TRUs) shall include an individual branch circuit and receptacle for operation of the refrigeration/heating units. The receptacle associated with the TRUs shall be provided in addition to the receptacles required in 626.24(B).

**(A) Branch Circuits.** TRU spaces shall be supplied from 208-volt, 3-phase or 480-volt, 3-phase branch circuits and with an equipment grounding conductor.

**(B) Electrified Truck Parking Space Supply Equipment.** The electrified truck parking space supply equipment, or portion thereof, providing electric power for the operation of TRUs shall be independent of the loads in Part III of Article 626.

### 626.31 Disconnecting Means and Receptacles

**(A) Disconnecting Means.** Disconnecting means shall be provided to isolate each refrigerated unit from its supply connection. A disconnecting means shall be provided and installed in a readily accessible location and shall be capable of being locked in the open position. Portable means for adding a lock to the switch or circuit breaker shall not be permitted as the means required to be installed at and remain with the equipment.

**(B) Location.** The disconnecting means shall be readily accessible, located not more than 750 mm (30 in.) from the receptacle it controls, and located in the supply circuit ahead of the receptacle. Circuit breakers or switches located in power outlets complying with this section shall be permitted as the disconnecting means.

**(C) Receptacles.** All receptacles shall be listed and of the grounding type. Every electrified truck parking space intended to provide an electrical supply for transport refrigerated units shall be equipped with one or both of the following:

- (1) A 30-ampere, 480-volt, 3-phase, 3-pole, 4-wire receptacle
- (2) A 60-ampere, 208-volt, 3-phase, 3-pole, 4-wire receptacle

Informational Note: Complete details of the 30-ampere pin and sleeve receptacle configuration for refrigerated containers (transport refrigerated units) can be found in ANSI/UL1686, *Standard for Pin and Sleeve Configurations*, Figure C2.11. For various configurations of 60-ampere pin and sleeve receptacles, see ANSI/UL1686.

### 626.32 Separable Power Supply Cable Assembly

A separable power supply cable assembly, consisting of a cord with an attachment plug and cord connector, shall be one of the types and ratings specified in 626.32(A), (B), and (C). Cords with adapters and pigtail ends, extension cords, and similar items shall not be used.

**(A) Rating(s).** The power supply cable assembly shall be listed and be rated in accordance with (1) or (2).

- (1) 30 ampere, 480-volt, 3-phase
- (2) 60 ampere, 208-volt, 3-phase

**(B) Cord Assemblies.** The cord shall be a listed type with four conductors, for 3-phase connection, one of which shall be identified in accordance with 400.23 for use as the equipment grounding conductor. Extra-hard usage cables rated not less than 90°C (194°F), 600 volts, listed for both wet locations and sunlight resistance, and having an outer jacket rated to be resistant to temperature extremes, oil, gasoline, ozone, abrasion, acids, and chemicals, shall be permitted where flexibility is necessary between the electrified truck parking space supply equipment and the inlet(s) on the TRU.

**(C) Attachment Plug(s) and Cord Connector(s).** Where a flexible cord is provided with an attachment plug and cord connector, they shall comply with 250.138(A). The attachment plug(s) and cord connector(s) shall be listed, by itself or as part of the power-supply cable assembly, for the purpose and shall be molded to or installed on the flexible cord so that it is secured tightly to the cord at the point where the cord enters the attachment plug or cord connector. If a right-angle cap is used, the configuration shall be oriented so that the grounding member is farthest from the cord. An attachment plug and cord connector for the connection of a truck or trailer shall be rated in accordance with (1) or (2) as follows:

- (1) 30-ampere, 480-volt, 3-phase, 3-pole, 4-wire and intended for use with a 30-ampere 480-volt, 3-phase, 3-pole, 4-wire receptacles and inlets, respectively, or
- (2) 60-ampere, 208-volt, 3-phase, 3-pole, 4-wire and intended for use with a 60-ampere, 208-volt, 3-phase, 3-pole, 4-wire receptacles and inlets, respectively.

Informational Note: Complete details of the 30-ampere pin and sleeve attachment plug and cord connector configurations for refrigerated containers (transport refrigerated units) can be found in ANSI/UL1686, *Standard for Pin and Sleeve Configurations*, Figures C2.12 and C2.11. For various configurations of 60-ampere pin and sleeve attachment plugs and cord connectors, see ANSI/UL1686.

I. General

630.1 Scope

This article covers apparatus for electric arc welding, resistance welding, plasma cutting, and other similar welding and cutting process equipment that is connected to an electrical supply system.

The two general types of electric welding are resistance welding and arc welding. Resistance welding, or “spot” welding, is the process of joining, or electrically fusing, two or more metal sheets or parts without any preparation of stock. The metal parts are placed between two electrodes or welding points, and a high current at a low voltage is passed through the electrodes. The metal parts offer resistance to the flow of current such that they heat to a molten state, and a weld is made.

Arc welding is the butting of two metal parts to be

welded, then the striking of an arc at this joint with a metal electrode (a flux-coated wire rod). The electrode itself is melted and supplies the extra metal necessary for joining the metal parts.

A transformer supplies current for one ac arc welder, and a generator or rectifier supplies current for one or more dc arc welders.

The scope of Article 630 also covers electrically supplied equipment associated with plasma cutting operations. This electrically powered equipment controls the flammable gas or gases used for cutting.

II. Arc Welders

630.11 Ampacity of Supply Conductors

The ampacity of conductors for arc welders shall be in accordance with 630.11(A) and (B).

(A) **Individual Welders.** The ampacity of the supply conductors shall be not less than the  $I_{\text{leff}}$  value on the rating plate. Alternatively, if the  $I_{\text{leff}}$  is not given, the ampacity of the supply conductors shall not be less than the current value determined by multiplying the rated primary current in amperes given on the welder rating plate by the factor shown in Table 630.11(A) based on the duty cycle of the welder.

TABLE 630.11(A) Duty Cycle Multiplication Factors for Arc Welders

Duty Cycle	Multiplier for Arc Welders	
	Nonmotor Generator	Motor Generator
100	1.00	1.00
90	0.95	0.96
80	0.89	0.91
70	0.84	0.86
60	0.78	0.81
50	0.71	0.75
40	0.63	0.69
30	0.55	0.62
20 or less	0.45	0.55

(B) **Group of Welders.** Minimum conductor ampacity shall be based on the individual currents determined in 630.11(A) as the sum of 100 percent of the two largest welders, plus 85 percent of the third largest welder, plus 70 percent of the fourth largest welder, plus 60 percent of all remaining welders.

*Exception: Percentage values lower than those given in 630.11(B) shall be permitted in cases where the work is*

*such that a high-operating duty cycle for individual welders is impossible.*

Informational Note: Duty cycle considers welder loading based on the use to be made of each welder and the number of welders supplied by the conductors that will be in use at the same time. The load value used for each welder considers both the magnitude and the duration of the load while the welder is in use.

Even under high-production conditions, the loads on transformer arc welders are considered intermittent. Therefore, the minimum ampacity of feeder conductors supplying several transformers (three or more) is permitted to be determined by applying the percentage values specified in 630.11(B). Intermittent transformer arc welder loads would be considerably less than a continuous load equal to the sum of the full-load current ratings of all the transformers. See also 630.31(B). The ampacity of conductors supplying welders is based on the  $I_{\text{eff}}$  rating on the welder rating plate. If the  $I_{\text{eff}}$  rating is not available, the size of supply conductors to welders may be calculated. The calculation is done by selecting the appropriate factor from Table 630.11(A) based on the type of welder and the duty cycle of the welder. The selected factor is then multiplied by the primary current rating from the welder rating plate to determine the minimum ampacity of the supply conductors.

The terms  $I_{\text{eff}}$  and  $I_{\text{imax}}$  are specified in the nameplate marking requirements of 630.14. The informational note includes a formula for  $I_{\text{eff}}$ , which is preferred over the value derived from using the factors in 630.11. The calculated value is still allowed.  $I_{\text{imax}}$  is basically the same as the rated primary current.

## 630.12 Overcurrent Protection

Overcurrent protection for arc welders shall be as provided in 630.12(A) and (B). Where the values as determined by this section do not correspond to the standard ampere ratings provided in 240.6 or where the rating or setting specified results in unnecessary opening of the overcurrent device, the next higher standard rating or setting shall be permitted.

**(A) For Welders.** Each welder shall have overcurrent protection rated or set at not more than 200 percent of  $I_{\text{imax}}$ . Alternatively, if the  $I_{\text{imax}}$  is not given, the overcurrent protection shall be rated or set at not more than 200 percent of the rated primary current of the welder.

An overcurrent device shall not be required for a welder that has supply conductors protected by an overcurrent device rated or set at not more than 200 percent of  $I_{\text{imax}}$  or at the rated primary current of the welder.

If the supply conductors for a welder are protected by an overcurrent device rated or set at not more than 200 per-

cent of  $I_{\text{imax}}$  or at the rated primary current of the welder, a separate overcurrent device shall not be required.

**(B) For Conductors.** Conductors that supply one or more welders shall be protected by an overcurrent device rated or set at not more than 200 percent of the conductor ampacity.

Informational Note:  $I_{\text{imax}}$  is the maximum value of the rated supply current at maximum rated output.  $I_{\text{eff}}$  is the maximum value of the effective supply current, calculated from the rated supply current ( $I_1$ ), the corresponding duty cycle (duty factor) ( $X$ ), and the supply current at no-load ( $I_0$ ) by the following equation:

$$I_{\text{eff}} = \sqrt{I_1^2 X + I_0^2 (1 - X)}$$

Some arc welding machines have a welding range involving an excess secondary-current output capacity beyond that indicated by the secondary rating marked on the machines. This excess capacity (generally not more than 150 percent of the marked output capacity) is usually supplied by means of one or more secondary taps in addition to the tap(s) intended for normal output current; the higher currents thus available are intended to provide for heavier welding work, including the use of larger-sized electrodes. This excess capacity is somewhat analogous to the inherent overload capacity of motors and transformers. However, the use of this excess current capacity and the overloading of welding machines, except for relatively short periods of time, could be hazardous and should be undertaken with caution.

### Calculation Example

A motor-generator-type electric arc welder has a nameplate primary current rating of 95 amperes and a duty cycle of 80 percent. Determine the minimum ampacity of the branch-circuit conductors and the maximum rating or setting for the branch-circuit overcurrent protective device.

#### Solution

STEP 1. Determine the minimum ampacity for the supply circuit conductors [630.11(A)]:

$$95 \text{ amperes} \times 0.91 \text{ (duty cycle factor)} = 86.45 \text{ amperes}$$

Copper THWN conductor selected from the 75°C column of Table 310.15(B)(16): 3 AWG (100-ampere allowable ampacity).

STEP 2. Determine the maximum rating or setting for the overcurrent protective device for the welder and the branch-circuit conductors [630.12(A) and (B)]:

$$95 \text{ amperes} \times 200\% = 190 \text{ amperes}$$

Next standard size OCPD: 200 amperes.

**Conclusion:** For this welder, the minimum conductor ampacity is 86.45 amperes and the maximum rating or setting

for the branch-circuit overcurrent protective device is 200 amperes. This rating or setting is the maximum permitted for a circuit supplying a single welder; however, the *Code* does not prohibit the use of a smaller-size OCPD. This minimum rating or setting is not specified by the *Code*, because that is a performance consideration related to the intended use of the welder.

### 630.13 Disconnecting Means

An identified disconnecting means shall be provided in the supply circuit for each arc welder that is not equipped with a disconnect mounted as an integral part of the welder.

The disconnecting means shall be a switch or circuit breaker, and its rating shall be not less than that necessary to accommodate overcurrent protection as specified under 630.12.

### 630.14 Marking

A rating plate shall be provided for arc welders giving the following information:

- (1) Name of manufacturer
- (2) Frequency
- (3) Number of phases
- (4) Primary voltage
- (5)  $I_{\text{max}}$  and  $I_{\text{eff}}$ , or rated primary current
- (6) Maximum open-circuit voltage
- (7) Rated secondary current
- (8) Basis of rating, such as the duty cycle

### 630.15 Grounding of Welder Secondary Circuit

The secondary circuit conductors of an arc welder, consisting of the electrode conductor and the work conductor, shall not be considered as premises wiring for the purpose of applying Article 250.

**Informational Note:** Connecting welder secondary circuits to grounded objects can create parallel paths and can cause objectionable current over equipment grounding conductors.

In theory and in accordance with the *NEC* definition of *separately derived system* in Article 100, the secondary circuit of an arc welder could be viewed as such a system. However, the intended operation of a welder is to create a high-current circuit between the electrode and the work surface. In the normal operation of an ac power distribution system, such an event would be considered a fault, and the operation of an overcurrent device to open the circuit and clear the fault is a fundamental concept of Articles 240 and 250. In the case of an arc welder, the opening of an overcurrent de-

vice is not intended unless the welding operation significantly exceeds the operating parameters of the welder. Grounding of a welder secondary terminal has the potential to cause excessive and potentially degrading parallel currents on power system equipment grounding conductors.

This requirement clarifies that for the purposes of Article 250 — specifically the requirements covering grounding of separately derived systems — the secondary circuit of a welder is not treated as premises wiring and is not required to be grounded as such. This provision modifies Article 250 for the purposes of electric welder secondary circuits and thereby removes any potential conflict where grounding in the welder secondary circuit occurs at the work object.

## III. Resistance Welders

### 630.31 Ampacity of Supply Conductors

The ampacity of the supply conductors for resistance welders necessary to limit the voltage drop to a value permissible for the satisfactory performance of the welder is usually greater than that required to prevent overheating as covered in 630.31(A) and (B).

**(A) Individual Welders.** The rated ampacity for conductors for individual welders shall comply with the following:

- (1) The ampacity of the supply conductors for a welder that may be operated at different times at different values of primary current or duty cycle shall not be less than 70 percent of the rated primary current for seam and automatically fed welders, and 50 percent of the rated primary current for manually operated nonautomatic welders.
- (2) The ampacity of the supply conductors for a welder wired for a specific operation for which the actual primary current and duty cycle are known and remain unchanged shall not be less than the product of the actual primary current and the multiplier specified in Table 630.31(A)(2) for the duty cycle at which the welder will be operated.

**(B) Groups of Welders.** The ampacity of conductors that supply two or more welders shall not be less than the sum of the value obtained in accordance with 630.31(A) for the largest welder supplied and 60 percent of the values obtained for all the other welders supplied.

**Informational Note: Explanation of Terms**

- (1) The *rated primary current* is the rated kilovolt-amperes (kVA) multiplied by 1000 and divided by the rated primary voltage, using values given on the nameplate.
- (2) The *actual primary current* is the current drawn from the supply circuit during each welder operation at the particular heat tap and control setting used.

**TABLE 630.31(A)(2) Duty Cycle Multiplication Factors for Resistance Welders**

Duty Cycle (%)	Multiplier
50	0.71
40	0.63
30	0.55
25	0.50
20	0.45
15	0.39
10	0.32
7.5	0.27
5 or less	0.22

- (3) The *duty cycle* is the percentage of the time during which the welder is loaded. For instance, a spot welder supplied by a 60-Hz system (216,000 cycles per hour) and making 400 15-cycle welds per hour would have a duty cycle of 2.8 percent (400 multiplied by 15, divided by 216,000, multiplied by 100). A seam welder operating 2 cycles “on” and 2 cycles “off” would have a duty cycle of 50 percent.

The ampacity of supply conductors for a welder that is not wired for a specific function (i.e., one operated at varying intervals for different applications, such as dissimilar metals or thicknesses) is permitted by 630.31(A)(1) to be 70 percent of the rated primary current for automatically fed welders and 50 percent of the rated primary current for manually operated welders.

#### Calculation Example

Determine the rated primary current using the following equation with the values given on the welder nameplate:

$$\text{Rated primary current} = \frac{\text{welder kVA} \times 1000}{\text{rated primary voltage}}$$

Where the actual primary current and the duty cycle are known, such as for a welder wired for a specific operation, the ampacity of the supply conductors is not permitted to be less than the product of the actual primary current (current drawn during weld operation) and the multiplier, as provided in 630.31(A)(2), for the duty cycle at which the welder will be operated.

For example, a spot welder is specifically set to perform 300 welds per hour on a 60-Hz system. Each weld draws current for 16 cycles. During the 1-hour period, the welder draws current for 4800 cycles (300 × 16). There are 216,000 cycles per hour (60 × 60 × 60). The duty cycle is calculated as follows:

$$\frac{4800}{216,000} \times 100\% = 2.2\% \text{ (duty cycle)}$$

For a seam welder that draws current for 3 cycles and is off for 4 cycles during every 7-cycle period, the duty cycle is calculated as follows:

$$\frac{3}{7} \times 100\% = 42.9\% \text{ (duty cycle)}$$

An instrument capable of measuring current impulses for 3 cycles ( $\frac{1}{20}$  second), as shown in the preceding example, is required to measure the actual primary current. The duty cycle is set for a specific operation by adjusting the controller for the welder. For the sizing of supply conductors, voltage drop should be limited to a value permissible for the satisfactory performance of the welder.

### 630.32 Overcurrent Protection

Overcurrent protection for resistance welders shall be as provided in 630.32(A) and (B). Where the values as determined by this section do not correspond with the standard ampere ratings provided in 240.6 or where the rating or setting specified results in unnecessary opening of the overcurrent device, a higher rating or setting that does not exceed the next higher standard ampere rating shall be permitted.

**(A) For Welders.** Each welder shall have an overcurrent device rated or set at not more than 300 percent of the rated primary current of the welder. If the supply conductors for a welder are protected by an overcurrent device rated or set at not more than 200 percent of the rated primary current of the welder, a separate overcurrent device shall not be required.

**(B) For Conductors.** Conductors that supply one or more welders shall be protected by an overcurrent device rated or set at not more than 300 percent of the conductor ampacity.

### 630.33 Disconnecting Means

A switch or circuit breaker shall be provided by which each resistance welder and its control equipment can be disconnected from the supply circuit. The ampere rating of this disconnecting means shall not be less than the supply conductor ampacity determined in accordance with 630.31. The supply circuit switch shall be permitted as the welder disconnecting means where the circuit supplies only one welder.

### 630.34 Marking

A nameplate shall be provided for each resistance welder, giving the following information:

- (1) Name of manufacturer
- (2) Frequency
- (3) Primary voltage
- (4) Rated kilovolt-amperes (kVA) at 50 percent duty cycle
- (5) Maximum and minimum open-circuit secondary voltage

- (6) Short-circuit secondary current at maximum secondary voltage
- (7) Specified throat and gap setting

## IV. Welding Cable

### 630.41 Conductors

Insulation of conductors intended for use in the secondary circuit of electric welders shall be flame retardant.

Listed welding cable is intended to be used for the secondary circuits of electric welders and cannot be used as “building wire” for circuits operating at 600 volts or less unless the cable is also one of the types covered in Table 310.104(A). The fine stranding allows for the flexibility necessary in manual and automatic welding operations. Terminals used with this type of cable must be suitable for use with the fine-stranding (34 AWG through 30 AWG) used in this type of cable construction. See 110.14 for more information regarding terminations used with conductors having other than Class B or C stranding.

### 630.42 Installation

Cables shall be permitted to be installed in a dedicated cable tray as provided in 630.42(A), (B), and (C).

**(A) Cable Support.** The cable tray shall provide support at not greater than 150-mm (6-in.) intervals.

**(B) Spread of Fire and Products of Combustion.** The installation shall comply with 300.21.

**(C) Signs.** A permanent sign shall be attached to the cable tray at intervals not greater than 6.0 m (20 ft). The sign shall read as follows:

CABLE TRAY FOR WELDING CABLES ONLY

## I. General

### 640.1 Scope

This article covers equipment and wiring for audio signal generation, recording, processing, amplification and reproduction; distribution of sound; public address; speech input systems; temporary audio system installations; and electronic organs or other electronic musical instruments. This also includes audio systems subject to Article 517, Part VI, and Articles 518, 520, 525, and 530.

Equipment covered by Article 640 includes amplifiers; public address (PA) systems and centralized sound systems used in schools, factories, businesses, stadiums, and similar locations; intercommunications devices and systems; and devices used for recording or reproducing voice or music. The scope is limited to equipment whose main function is the processing, distribution, amplification, and reproduction of audio frequency bandwidth signals. This limitation does not preclude equipment that uses radio frequency or other forms of transmission between equipment components, such as wireless microphone systems.

Electronic organs are synthesizers, and synthesizers also generate audio signals. For the sake of clarity, electronic organs are uniquely cited in the scope, and electronic musical

instruments are included to cover all other forms of electronic tone generation. Electronic musical instruments create an electronic signal as their sole or primary output and require amplification and reproduction equipment to be audible.

Informational Note No. 1: Examples of permanently installed distributed audio system locations include, but are not limited to, restaurant, hotel, business office, commercial and retail sales environments, churches, and schools. Both portable and permanently installed equipment locations include, but are not limited to, residences, auditoriums, theaters, stadiums, and movie and television studios. Temporary installations include, but are not limited to, auditoriums, theaters, stadiums (which use both temporary and permanently installed systems), and outdoor events such as fairs, festivals, circuses, public events, and concerts.

Informational Note No. 2: Fire and burglary alarm signaling devices are specifically not encompassed by this article.

### 640.2 Definitions

For purposes of this article, the following definitions apply.

**Abandoned Audio Distribution Cable.** Installed audio distribution cable that is not terminated at equipment and not identified for future use with a tag.

**Audio Amplifier or Pre-Amplifier.** Electronic equipment that increases the current or voltage, or both, potential of an audio signal intended for use by another piece of audio equipment. *Amplifier* is the term used to denote an audio amplifier within this article.

**Audio Autotransformer.** A transformer with a single winding and multiple taps intended for use with an amplifier loudspeaker signal output.

**Audio Signal Processing Equipment.** Electrically operated equipment that produces, processes, or both, electronic signals that, when appropriately amplified and reproduced by a loudspeaker, produce an acoustic signal within the range of normal human hearing (typically 20–20 kHz). Within this article, the terms *equipment* and *audio equipment* are assumed to be equivalent to audio signal processing equipment.

Informational Note: This equipment includes, but is not limited to, loudspeakers; headphones; pre-amplifiers; microphones and their power supplies; mixers; MIDI (musical instrument digital interface) equipment or other digital control systems; equalizers, compressors, and other audio signal processing equipment; and audio media recording and playback equipment, including turntables, tape decks and disk players (audio and multimedia), synthesizers, tone generators, and electronic organs. Electronic organs and synthesizers may have integral or separate amplification and loudspeakers. With the exception of amplifier outputs, virtually all such equipment is used to process signals (utilizing analog or digital techniques) that have nonhazardous levels of voltage or current potential.

The definition of *audio signal processing equipment* clarifies the limits of signal processing (frequency bandwidth), which falls under Article 640. The informational note enumerates the breadth of equipment considered to fall within the defined scope of Article 640. It is intended to provide a sufficiently broad list of current technology equipment to assist in determining the applicability of Article 640 to the equipment under review.

“MIDI (musical instrument digital interface) equipment or other digital control systems” is mentioned specifically because, while MIDI or similar digital control signals may issue from an electronic musical instrument, such signals also can be obtained from a computer that is appropriately configured to perform similar controlling functions.

**Audio System.** Within this article, the totality of all equipment and interconnecting wiring used to fabricate a fully functional audio signal processing, amplification, and reproduction system.

**Audio Transformer.** A transformer with two or more electrically isolated windings and multiple taps intended for use with an amplifier loudspeaker signal output.

The definition of *audio transformer* is included to clearly state that such transformers are intended only for use with audio signals, not light and power.

**Equipment Rack.** A framework for the support, enclosure, or both, of equipment; may be portable or stationary. See ANSI/EIA/310-D-1992, *Cabinets, Racks, Panels and Associated Equipment*.

ANSI/EIA 310-D-1992, *Cabinets, Racks, Panels and Associated Equipment*, defines *commercial equipment racks*. However, custom-fabricated racks that utilize equipment mounting hole patterns that generally comply with this standard might not be constructed of steel. Within Article 640, both *equipment rack* and *rack* are used to refer to equipment enclosures that are conceptually similar in intended use to those defined by the ANSI/EIA standard.

**Loudspeaker.** Equipment that converts an ac electric signal into an acoustic signal. The term *speaker* is commonly used to mean *loudspeaker*.

Typical peak signal operating voltages for such equipment vary from a few millivolts for microphones to 2 to 4 volts for

disk players. A mixer’s purpose is to balance these inputs to provide (typically) a 1-volt peak output signal to an amplifier.

**Maximum Output Power.** The maximum output power delivered by an amplifier into its rated load as determined under specified test conditions. This may exceed the manufacturer’s rated output power for the same amplifier.

**Mixer.** Equipment used to combine and level match a multiplicity of electronic signals, such as from microphones, electronic instruments, and recorded audio.

**Mixer–Amplifier.** Equipment that combines the functions of a mixer and amplifier within a single enclosure.

**Portable Equipment.** Equipment fed with portable cords or cables intended to be moved from one place to another.

**Powered Loudspeaker.** Equipment that consists of a loudspeaker and amplifier within the same enclosure. Other signal processing may also be included.

**Rated Load Impedance.** The amplifier manufacturer’s stated or marked speaker impedance into which an amplifier will deliver its rated output power; 2Ω, 4Ω, and 8Ω are typical ratings.

**Rated Output Power.** The amplifier manufacturer’s stated or marked output power capability into its rated load.

**Rated Output Voltage.** For audio amplifiers of the constant-voltage type, the nominal output voltage when the amplifier is delivering full rated power. Rated output voltage is used for determining approximate acoustic output in distributed speaker systems that typically employ impedance matching transformers. Typical ratings are 25 volts, 70.7 volts, and 100 volts.

**Technical Power System.** An electrical distribution system with grounding in accordance with 250.146(D), where the equipment grounding conductor is isolated from the premises grounded conductor except at a single grounded termination point within a branch-circuit panelboard, at the originating (main breaker) branch-circuit panelboard, or at the premises grounding electrode.

The terms *technical power* and *technical ground* are commonly used by audio/video technicians and electricians to designate a wiring system that is in compliance with 250.146(D). Including the definition of *technical power system* in Article 640 is intended to broaden the scope of this term to include the commonly employed distribution systems fabricated in compliance with 250.146(D).

**Temporary Equipment.** Portable wiring and equipment intended for use with events of a transient or temporary nature where all equipment is presumed to be removed at the conclusion of the event.

Temporary equipment may be used in facilities of a permanent or temporary nature or with no facilities other than a source of electrical power. Locations include indoor and outdoor areas such as athletic facilities, halls, auditoriums, concert shells, athletic fields, beaches, and other places designated for public assembly.

### 640.3 Locations and Other Articles

Circuits and equipment shall comply with 640.3(A) through (M), as applicable.

**(A) Spread of Fire or Products of Combustion.** Section 300.21 shall apply.

**(B) Ducts, Plenums, and Other Air-Handling Spaces.** See 300.22 for circuits and equipment installed in ducts or plenums or other space used for environmental air.

Informational Note: NFPA 90A-2009, *Standard for the Installation of Air Conditioning and Ventilation Systems*, Section 4.3.10.2.6.5, permits loudspeakers, loudspeaker assemblies, and their accessories listed in accordance with UL 2043-1996, *Fire Test for Heat and Visible Smoke Release for Discrete Products and Their Accessories Installed in Air-Handling Spaces*, to be installed in other spaces used for environmental air (ceiling cavity plenums).

**(C) Cable Trays.** Cable trays shall be used in accordance with Article 392.

Informational Note: See 725.154(C) for the use of Class 2, Class 3, and Type PLTC cable in cable trays.

**(D) Hazardous (Classified) Locations.** Equipment used in hazardous (classified) locations shall comply with the applicable requirements of Chapter 5.

**(E) Assembly Occupancies.** Equipment used in assembly occupancies shall comply with Article 518.

The examples of assembly occupancies described in 518.2 are some of the most common locations for the installation of both distributed audio systems (e.g., background music) and centralized systems (permanently installed sound reinforcement systems for meeting rooms, auditoriums, gymnasiums, and the like).

**(F) Theaters, Audience Areas of Motion Picture and Television Studios, and Similar Locations.** Equipment

used in theaters, audience areas of motion picture and television studios, and similar locations shall comply with Article 520.

**(G) Carnivals, Circuses, Fairs, and Similar Events.** Equipment used in carnivals, circuses, fairs, and similar events shall comply with Article 525.

**(H) Motion Picture and Television Studios.** Equipment used in motion picture and television studios shall comply with Article 530.

**(I) Swimming Pools, Fountains, and Similar Locations.** Audio equipment used in or near swimming pools, fountains, and similar locations shall comply with Article 680.

The underwater installation of audio equipment in swimming pools is covered in 680.27. The acceptable placement, wiring, and use of equipment used near (rather than immersed in) bodies of water, both natural and artificial, are covered in 640.10.

**(J) Combination Systems.** Where the authority having jurisdiction permits audio systems for paging or music, or both, to be combined with fire alarm systems, the wiring shall comply with Article 760.

Informational Note: For installation requirements for such combination systems, refer to NFPA 72-2010, *National Fire Alarm and Signaling Code*, and NFPA 101-2009, *Life Safety Code*.

In addition to alarm tones, fire alarm systems frequently use loudspeakers for verbal announcements. All such systems must comply with Article 760 and NFPA 72®, *National Fire Alarm and Signaling Code*. Audio systems that use a paging or background music system are permitted to be used as part of a fire alarm warning system, but they require compliance with Article 760. The installation of fire alarm systems is governed by NFPA 72. Refer to NFPA 101®, *Life Safety Code*®, for multipurpose systems.

**(K) Antennas.** Equipment used in audio systems that contain an audio or video tuner and an antenna input shall comply with Article 810. Wiring other than antenna wiring that connects such equipment to other audio equipment shall comply with this article.

The term *receiver* is commonly used in the consumer market to mean an amplifier combined with a radio tuner (typically AM/FM) and other signal processing and/or switching

functions. Except for the tuner function and the antenna input, the signal processing functions are the same as those provided by equipment in Article 640. Article 810, Part II, covers the antenna installation for such equipment, and 810.3 references Article 640 as appropriate for wiring requirements (other than for the antenna).

**(L) Generators.** Generators shall be installed in accordance with 445.10 through 445.12, 445.14 through 445.16, and 445.18. Grounding of portable and vehicle-mounted generators shall be in accordance with 250.34.

**(M) Organ Pipes.** Additions of pipe organ pipes to an electronic organ shall be in accordance with 650.4 through 650.8.

### 640.4 Protection of Electrical Equipment

Amplifiers, loudspeakers, and other equipment shall be so located or protected as to guard against environmental exposure or physical damage, such as might result in fire, shock, or personal hazard.

### 640.5 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels, including suspended ceiling panels.

### 640.6 Mechanical Execution of Work

**(A) Neat and Workmanlike Manner.** Audio signal processing, amplification, and reproduction equipment, cables, and circuits shall be installed in a neat workmanlike manner.

**(B) Installation of Audio Distribution Cables.** Cables installed exposed on the surface of ceilings and sidewalls shall be supported in such a manner that the audio distribution cables will not be damaged by normal building use. Such cables shall be secured by straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall conform to 300.4 and 300.11(A).

Where installed in the hollow space above a suspended, dropped, or similar ceiling, cables of audio systems covered in Article 640 are required to be supported in accordance with 300.11. Without documentation from the manufacturer of the ceiling system providing specific instruction on the use of the ceiling system support wires as a means to support wiring methods, an independent support system for the cables must be installed. Additional ceiling wires installed spe-

cifically for the purpose of supporting the audio system wiring are required to be secured in place. Attachment of the additional support wires to the ceiling system and to the building structure above the ceiling provides the secure support required by 300.11(A)(1) and (A)(2). The use of securing hardware such as straps, staples, cable ties, hangers, or other approved means is required and must be installed so as not to damage the audio cable. The *Code* does not specify the distance between securing points.

**(C) Abandoned Audio Distribution Cables.** The accessible portion of abandoned audio distribution cables shall be removed.

### (D) Installed Audio Distribution Cable Identified for Future Use.

(1) Cables identified for future use shall be marked with a tag of sufficient durability to withstand the environment involved.

(2) Cable tags shall have the following information:

- (1) Date cable was identified for future use
- (2) Date of intended use
- (3) Information related to the intended future use of cable

### 640.7 Grounding

**(A) General.** Wireways and auxiliary gutters shall be connected to an equipment grounding conductor(s), to an equipment bonding jumper, or to the grounded conductor where permitted or required by 250.92(B)(1) or 250.142. Where the wireway or auxiliary gutter does not contain power-supply wires, the equipment grounding conductor shall not be required to be larger than 14 AWG copper or its equivalent. Where the wireway or auxiliary gutter contains power-supply wires, the equipment grounding conductor shall not be smaller than specified in 250.122.

**(B) Separately Derived Systems with 60 Volts to Ground.** Grounding of separately derived systems with 60 volts to ground shall be in accordance with 647.6.

**(C) Isolated Ground Receptacles.** Isolated grounding-type receptacles shall be permitted as described in 250.146(D), and for the implementation of other technical power systems in compliance with Article 250. For separately derived systems with 60 volts to ground, the branch-circuit equipment grounding conductor shall be terminated as required in 647.6(B).

Informational Note: See 406.3(D) for grounding-type receptacles and required identification.

The reference to 647.6 in 640.7(B) provides guidance for grounding separately derived systems operating at 60 volts to ground. Such separately derived systems are used as a technique for the reduction of electromagnetic noise in audio systems and in video systems.

The intent of 640.7(C) is to clarify the proper use of isolated ground receptacles when used with technical power systems of the type that are separately derived systems with 60 volts to ground.

## 640.8 Grouping of Conductors

Insulated conductors of different systems grouped or bundled so as to be in close physical contact with each other in the same raceway or other enclosure, or in portable cords or cables, shall comply with 300.3(C)(1).

## 640.9 Wiring Methods

### (A) Wiring to and Between Audio Equipment.

**(1) Power Wiring.** Wiring and equipment from source of power to and between devices connected to the premises wiring systems shall comply with the requirements of Chapters 1 through 4, except as modified by this article.

**(2) Separately Derived Power Systems.** Separately derived systems shall comply with the applicable articles of this *Code*, except as modified by this article. Separately derived systems with 60 volts to ground shall be permitted for use in audio system installations as specified in Article 647.

**(3) Other Wiring.** All wiring not connected to the premises wiring system or to a wiring system separately derived from the premises wiring system shall comply with Article 725.

**(B) Auxiliary Power Supply Wiring.** Equipment that has a separate input for an auxiliary power supply shall be wired in compliance with Article 725. Battery installation shall be in accordance with Article 480. **This section shall not apply to the use of uninterruptible power supply (UPS) equipment, or other sources of supply, that are intended to act as a direct replacement for the primary circuit power source and are connected to the primary circuit input.**

Informational Note: Refer to *NFPA 72-2010, National Fire Alarm and Signaling Code*, where equipment is used for a fire alarm system.

Audio equipment with a separate input for an auxiliary power supply is typically used for emergency paging or fire alarm systems. These auxiliary power-supply inputs typi-

cally range from 12 to 48 volts dc. Article 480 adequately covers installation and overcurrent protection of battery circuits of this type. The term *auxiliary* is used to indicate that the equipment is also capable of being powered by the premises wiring system through an independent input connector, cord, or cable.

A replacement source for the premises wiring system such as a UPS or a standby generator is not covered by the requirements of this section unless it is directly connected to the auxiliary power-supply input and supplies the audio equipment with a dc voltage.

**(C) Output Wiring and Listing of Amplifiers.** Amplifiers with output circuits carrying audio program signals shall be permitted to employ Class 1, Class 2, or Class 3 wiring where the amplifier is listed and marked for use with the specific class of wiring method. Such listing shall ensure the energy output is equivalent to the shock and fire risk of the same class as stated in Article 725. Overcurrent protection shall be provided and shall be permitted to be inherent in the amplifier.

Audio amplifier output circuits wired using Class 1 wiring methods shall be considered equivalent to Class 1 circuits and shall be installed in accordance with 725.46, where applicable.

Audio amplifier output circuits wired using Class 2 or Class 3 wiring methods shall be considered equivalent to Class 2 or Class 3 circuits, respectively. They shall use conductors insulated at not less than the requirements of 725.179 and shall be installed in accordance with 725.133 and 725.154.

Informational Note No. 1: ANSI/UL 1711-1994, *Amplifiers for Fire Protective Signaling Systems*, contains requirements for the listing of amplifiers used for fire alarm systems in compliance with *NFPA 72-2010, National Fire Alarm and Signaling Code*.

Informational Note No. 2: Examples of requirements for listing amplifiers used in residential, commercial, and professional use are found in ANSI/UL 813-1996, *Commercial Audio Equipment*; ANSI/UL 1419-1997, *Professional Video and Audio Equipment*; ANSI/UL 1492-1996, *Audio-Video Products and Accessories*; and ANSI/UL 6500-1996, *Audio/Video and Musical Instrument Apparatus for Household, Commercial, and Similar Use*.

**(D) Use of Audio Transformers and Autotransformers.** Audio transformers and autotransformers shall be used only for audio signals in a manner so as not to exceed the manufacturer's stated input or output voltage, impedance, or power limitations. The input or output wires of an audio transformer or autotransformer shall be allowed to connect directly to the amplifier or loudspeaker terminals. No electrical terminal or lead shall be required to be grounded or bonded.

Audio transformers and autotransformers are commonly used between the amplifier output and the loudspeaker input for the following reasons:

1. At the output of the amplifier to change the amplifier's operating voltage to match the design impedance of the loudspeaker
2. At the loudspeaker, where the inherently low voice coil impedance is raised, to match the output voltage of the amplifier (or autotransformer)
3. Between the amplifier output and loudspeaker input as an attenuating device (volume control)

Audio autotransformers are similar in concept to autotransformers used for light and power, but they are not designed for such use. Audio transformers are commonly used to provide electrical isolation of the speakers from the signal source. Either type of audio transformer (two winding or autotransformer) is frequently referred to as an "impedance matching transformer."

The last sentence of 640.9(D) specifically addresses the fact that electrical terminals are not to be treated in the same manner as transformers used for light and power might be (e.g., grounding the common terminal of an autotransformer). Some amplifier outputs are deliberately isolated from equipment ground, in which case such a connection could damage the amplifier and violate the manufacturer's recommended use. The frame of the transformer may or may not require bonding, depending on the manufacturer's installation instructions.

### 640.10 Audio Systems Near Bodies of Water

Audio systems near bodies of water, either natural or artificial, shall be subject to the restrictions specified in 640.10(A) and (B).

*Exception: This section does not include audio systems intended for use on boats, yachts, or other forms of land or water transportation used near bodies of water, whether or not supplied by branch-circuit power.*

Informational Note: See 680.27(A) for installation of underwater audio equipment.

#### (A) Equipment Supplied by Branch-Circuit Power.

Audio system equipment supplied by branch-circuit power shall not be placed laterally within 1.5 m (5 ft) of the inside wall of a pool, spa, hot tub, or fountain, or within 1.5 m (5 ft) of the prevailing or tidal high water mark. The equipment shall be provided with branch-circuit power protected by a ground-fault circuit interrupter where required by other articles.

Article 680 is limited by its scope to the use of underwater loudspeakers. This particular application for audio equipment is unique in construction and wiring to pools and is appropriate for Article 680.

Other locations where audio equipment might be used "near bodies of water" are not addressed in Article 680. The purpose of 640.10(A), in conjunction with the other requirements of Article 640, is to address locations where audio equipment is used near bodies of water.

The exception to 640.10 excludes sound systems on vehicles used in or near water, such as amphibious vehicles and boats of all sizes.

The term *prevailing or tidal high water mark* recognizes that the edges of natural bodies of water can advance or recede. This phrase makes clear that such changes can be anticipated.

The requirement for use of a GFCI is placed here to ensure that personnel are properly protected. Where the equipment (specifically an amplifier or a receiver) is installed in an electrical cabinet or a room not near a body of water, the requirement for GFCI protection does not apply, unless required by other sections of the *Code*.

#### (B) Equipment Not Supplied by Branch-Circuit Power.

Audio system equipment powered by a listed Class 2 power supply or by the output of an amplifier listed as permitting the use of Class 2 wiring shall be restricted in placement only by the manufacturer's recommendations.

Informational Note: Placement of the power supply or amplifier, if supplied by branch-circuit power, is still subject to 640.10(A).

## II. Permanent Audio System Installations

Permanent audio systems are characterized by fixed locations for the wiring, signal processing equipment, and reproduction equipment. Wiring is attached to the building structure and is frequently concealed. Speakers in commercial, hospital, school, and restaurant areas are commonly recessed into ceiling or wall surfaces, or they are mounted to structure surfaces using brackets, usually beyond the reach of a standing person.

### 640.21 Use of Flexible Cords and Cables

#### (A) Between Equipment and Branch-Circuit Power.

Power supply cords for audio equipment shall be suitable for the use and shall be permitted to be used where the interchange, maintenance, or repair of such equipment is facilitated through the use of a power-supply cord.

Some loudspeakers are specifically identified as being for outdoor use. The requirements of 110.11 specify that electrical equipment and conductors be identified for use in the operating environment. This general requirement applies to equipment and conductors used in conjunction with the installation of audio equipment. Exhibit 640.1 shows a loudspeaker identified for outdoor use. The conductors supplying this outdoor speaker must also be identified for the environment.

**EXHIBIT 640.1** Loudspeaker for outdoor use above ground or partially in ground. (Courtesy of Bose Corp.)

**(B) Between Loudspeakers and Amplifiers or Between Loudspeakers.** Cables used to connect loudspeakers to each other or to an amplifier shall comply with Article 725. Other listed cable types and assemblies, including optional hybrid communications, signal, and **composite** optical fiber cables, shall be permitted.

**(C) Between Equipment.** Cables used for the distribution of audio signals between equipment shall comply with Article 725. Other listed cable types and assemblies, including optional hybrid communications, signal, and **composite** optical fiber cables, shall be permitted. Other cable types and assemblies specified by the equipment manufacturer as acceptable for the use shall be permitted in accordance with 110.3(B).

**(D) Between Equipment and Power Supplies Other Than Branch-Circuit Power.** The following power supplies, other than branch-circuit power supplies, shall be installed and wired between equipment in accordance with the requirements of this *Code* for the voltage and power delivered:

- (1) Storage batteries
- (2) Transformers
- (3) Transformer rectifiers
- (4) Other ac or dc power supplies

Informational Note: For some equipment, these sources such as in items (1) and (2) serve as the only source of power. These could, in turn, be supplied with intermittent or continuous branch-circuit power.

**(E) Between Equipment Racks and Premises Wiring System.** Flexible cords and cables shall be permitted for the electrical connection of permanently installed equipment racks to the premises wiring system to facilitate access to equipment or for the purpose of isolating the technical power system of the rack from the premises ground. Connection shall be made either by using approved plugs and receptacles or by direct connection within an approved enclosure. Flexible cords and cables shall not be subjected to physical manipulation or abuse while the rack is in use.

#### 640.22 Wiring of Equipment Racks and Enclosures

Metal equipment racks and enclosures shall be grounded. Bonding shall not be required if the rack is connected to a technical power ground.

Equipment racks shall be wired in a neat and workmanlike manner. Wires, cables, structural components, or other equipment shall not be placed in such a manner as to prevent reasonable access to equipment power switches and resettable or replaceable circuit overcurrent protection devices.

Supply cords or cables, if used, shall terminate within the equipment rack enclosure in an identified connector assembly. The supply cords or cable (and connector assembly if used) shall have sufficient ampacity to carry the total load connected to the equipment rack and shall be protected by overcurrent devices.

#### 640.23 Conduit or Tubing

**(A) Number of Conductors.** The number of conductors permitted in a single conduit or tubing shall not exceed the percentage fill specified in Table 1, Chapter 9.

**(B) Nonmetallic Conduit or Tubing and Insulating Bushings.** The use of nonmetallic conduit or tubing and insulating bushings shall be permitted where a technical power system is employed and shall comply with applicable articles.

#### 640.24 Wireways, Gutters, and Auxiliary Gutters

The use of metallic and nonmetallic wireways, gutters, and auxiliary gutters shall be permitted for use with audio signal

conductors and shall comply with applicable articles with respect to permitted locations, construction, and fill.

### 640.25 Loudspeaker Installation in Fire Resistance-Rated Partitions, Walls, and Ceilings

Loudspeakers installed in a fire resistance-rated partition, wall, or ceiling shall be listed for that purpose or installed in an enclosure or recess that maintains the fire resistance rating.

**Informational Note:** Fire-rated construction is the fire-resistive classification used in building codes. One method of determining fire rating is testing in accordance with NFPA 256-2003, *Standard Methods of Fire Tests of Roof Coverings*.

Section 640.25 requires an enclosure that maintains the requisite fire resistance rating of the wall or ceiling in which a flush-mount loudspeaker is installed. Listed enclosures are available for this purpose, but prior to their availability, site-built enclosures were installed with the approval of the authority having jurisdiction and have been used as a method to maintain the fire resistance rating of the wall or ceiling.

## III. Portable and Temporary Audio System Installations

Portable and temporary audio system installations are characterized by the portable nature of the signal processing equipment and the reproduction equipment. While the equipment may not differ fundamentally from that used in permanent installations, the enclosures that serve as portable equipment racks provide both transit protection and mechanical protection while the equipment is in use. Such enclosures may accommodate one or multiple pieces of equipment and may be of metal, wood, plastic, or reinforced plastic construction. The nonmetal construction enclosures frequently do not comply with ANSI/EIA 310-D-1992, *Cabinets, Racks, Panels and Associated Equipment*, except for the mounting attachment points for the equipment.

### 640.41 Multipole Branch-Circuit Cable Connectors

Multipole branch-circuit cable connectors, male and female, for power-supply cords and cables shall be so constructed that tension on the cord or cable is not transmitted to the connections. The female half shall be attached to the load end of the power supply cord or cable. The connector shall be rated in amperes and designed so that differently rated devices cannot be connected together. Alternating-current

multipole connectors shall be polarized and comply with 406.7(A) and (B) and 406.10. Alternating-current or direct-current multipole connectors utilized for connection between loudspeakers and amplifiers, or between loudspeakers, shall not be compatible with nonlocking 15- or 20-ampere rated connectors intended for branch-circuit power or with connectors rated 250 volts or greater and of either the locking or nonlocking type. Signal cabling not intended for such loudspeaker and amplifier interconnection shall not be permitted to be compatible with multipole branch-circuit cable connectors of any accepted configuration.

**Informational Note:** See 400.10 for pull at terminals.

### 640.42 Use of Flexible Cords and Cables

**(A) Between Equipment and Branch-Circuit Power.** Power supply cords for audio equipment shall be listed and shall be permitted to be used where the interchange, maintenance, or repair of such equipment is facilitated through the use of a power-supply cord.

**(B) Between Loudspeakers and Amplifiers, or Between Loudspeakers.** Flexible cords and cables used to connect loudspeakers to each other or to an amplifier shall comply with Article 400 and Article 725, respectively. Cords and cables listed for portable use, either hard or extra-hard usage as defined by Article 400, shall also be permitted. Other listed cable types and assemblies, including optional hybrid communications, signal, and optical fiber cables, shall be permitted.

**(C) Between Equipment and/or Between Equipment Racks.** Flexible cords and cables used for the distribution of audio signals between equipment shall comply with Article 400 and Article 725, respectively. Cords and cables listed for portable use, either hard or extra-hard service as defined by Article 400, shall also be permitted. Other listed cable types and assemblies, including optional hybrid communications, signal, and optical fiber cables, shall be permitted.

**(D) Between Equipment, Equipment Racks, and Power Supplies Other Than Branch-Circuit Power.** Wiring between the following power supplies, other than branch-circuit power supplies, shall be installed, connected, or wired in accordance with the requirements of this *Code* for the voltage and power required:

- (1) Storage batteries
- (2) Transformers
- (3) Transformer rectifiers
- (4) Other ac or dc power supplies

**(E) Between Equipment Racks and Branch-Circuit Power.** The supply to a portable equipment rack shall be by

means of listed extra-hard usage cords or cables, as defined in Table 400.4. For outdoor portable or temporary use, the cords or cables shall be further listed as being suitable for wet locations and sunlight resistant. Sections 520.5, 520.10, and 525.3 shall apply as appropriate when the following conditions exist:

- (1) Where equipment racks include audio and lighting and/or power equipment
- (2) When using or constructing cable extensions, adapters, and breakout assemblies

### 640.43 Wiring of Equipment Racks

Equipment racks fabricated of metal l be grounded. Nonmetallic racks with covers (if provided) removed shall not allow access to Class 1, Class 3, or primary circuit power without the removal of covers over terminals or the use of tools.

Equipment racks shall be wired in a neat and workmanlike manner. Wires, cables, structural components, or other equipment shall not be placed in such a manner as to prevent reasonable access to equipment power switches and resettable or replaceable circuit overcurrent protection devices.

Wiring that exits the equipment rack for connection to other equipment or to a power supply shall be relieved of strain or otherwise suitably terminated such that a pull on the flexible cord or cable will not increase the risk of damage to the cable or connected equipment such as to cause an unreasonable risk of fire or electric shock.

### 640.44 Environmental Protection of Equipment

Portable equipment not listed for outdoor use shall be permitted only where appropriate protection of such equipment from adverse weather conditions is provided to prevent risk of fire or electric shock. Where the system is intended to remain operable during adverse weather, arrangements shall be made for maintaining operation and ventilation of heat-dissipating equipment.

Although most portable audio equipment used in temporary audio systems is not listed for outdoor use, 640.44 permits such equipment to be used with an appropriate enclosure or other means to protect the equipment from anticipated adverse weather conditions.

### 640.45 Protection of Wiring

Where accessible to the public, flexible cords and cables laid or run on the ground or on the floor shall be covered with approved nonconductive mats. Cables and mats shall be arranged so as not to present a tripping hazard. **The cover re-**

quirements of 300.5 shall not apply to wiring protected by burial.

### 640.46 Equipment Access

Equipment likely to present a risk of fire, electric shock, or physical injury to the public shall be protected by barriers or supervised by qualified personnel so as to prevent public access.

Informational Note: Text that is followed by a reference in brackets has been extracted from NFPA 75-2009, *Standard for the Protection of Information Technology Equipment*.

Only editorial changes were made to the extracted text to make it consistent with this *Code*.

### 645.1 Scope

This article covers equipment, power-supply wiring, equipment interconnecting wiring, and grounding of information technology equipment and systems in an information technology equipment room.

**Informational Note:** For further information, see NFPA 75-2009, *Standard for the Protection of Information Technology Equipment*, which covers the requirements for the protection of information technology equipment and information technology equipment areas.

The term *information technology equipment* (ITE) replaces other terms that describe computer-based business, personal, and industrial equipment. This terminology is also used by UL 60950-1, *Safety of Information Technology, Part 1: General Requirements*, as well as by international standards, as a more inclusive term for the equipment addressed by Article 645.

Article 645 applies only to equipment and systems, including the associated wiring, located within the ITE room. An ITE room is an enclosed area, with one or more means of entry that contains computer-based business and industrial equipment. It is designed to comply with the special construction and fire protection provisions of NFPA 75, as well as 645.4 of the *Code*.

Small terminals, such as remote telephone terminal units, remote data terminals, personal computers, and cash registers in stores and supermarkets, are not covered by Article 645.

### 645.2 Definitions

**Abandoned Supply Circuits and Interconnecting Cables.** Installed supply circuits and interconnecting cables that are not terminated at equipment and not identified for future use with a tag.

**Critical Operations Data System.** An information technology equipment system that requires continuous operation for reasons of public safety, emergency management, national security, or business continuity.

Similar to the application of Article 708 covering critical operations power systems, designation of which information technology systems are critical in function is the responsibility of the authority having jurisdiction, which in many cases may be an emergency management director or similar person rather than the electrical AHJ. Once the system is designated as being *critical*, the AHJ responsible for approving the installation ensures compliance with the applicable requirements of Article 645.

**Information Technology Equipment (ITE).** Equipment and systems rated 600 volts or less, normally found in offices or other business establishments and similar environments classified as ordinary locations, that are used for creation and manipulation of data, voice, video, and similar signals that are not communications equipment as defined in Part I of Article 100 and do not process communications circuits as defined in 800.2.

This definition clearly delineates equipment that is subject to the requirements of this article from communications equipment covered in Article 800. It is not uncommon for ITE equipment and communications equipment to be installed in the same information technology equipment room.

**Informational Note:** For information on listing requirements for both information technology equipment and communications equipment, see UL 60950-1-2007, *Information Technology Equipment - Safety - Part 1: General Requirements*.

**Information Technology Equipment Room.** A room within the information technology equipment area that contains the information technology equipment. [75:3.3.9]

**Remote Disconnect Control.** An electric device and circuit that controls a disconnecting means through a relay or equivalent device.

**Zone.** A physically identifiable area (such as barriers or separation by distance) within an information technology equipment room, with dedicated power and cooling systems for the information technology equipment or systems.

### 645.3 Other Articles.

Circuits and equipment shall comply with 645.3(A) through (G), as applicable.

**(A) Spread of Fire or Products of Combustion.** Sections 300.21, 770.26, 800.26, and 820.26 shall apply to penetrations of the fire-resistant room boundary.

**(B) Plenums.** Sections 300.22(C)(1), 725.154(A), 760.53(B)(2), 760.154(A), 770.113(C), 800.113(C), and 820.113(C) and Tables 770.154(A), 800.154(A) and 820.154(A) shall apply to wiring and cabling in a plenum (other space used for environmental air) above an information technology equipment room.

**(C) Grounding.** The non-current-carrying conductive members of optical fiber cables in an information technology equipment room shall be grounded in accordance with 770.114.

**(D) Electrical Classification of Data Circuits.** Section 725.121(A)(4) shall apply to the electrical classification of listed information technology equipment signaling circuits. Section 725.139(D)(1) and 800.133(A)(1)(b) shall apply to the electrical classification of Class 2 and Class 3 circuits in the same cable with communications circuits.

**(E) Fire Alarm Equipment.** Parts I, II, and III of Article 760 shall apply to fire alarm systems equipment installed in an information technology equipment room.

**(F) Communications Equipment.** Parts I, II, III, IV, and V of Article 800 shall apply to communications equipment installed in an information technology equipment room. Article 645 shall apply to the powering of communications equipment in an information technology equipment room.

Informational Note: See Part I of Article 100, Definitions, for a definition of communications equipment.

**(G) Community Antenna Television and Radio Distribution Systems Equipment.** Parts I, II, III, IV, and V of Article 820 shall apply to community antenna television and radio distribution systems equipment installed in an information technology equipment room. Article 645 shall apply to the powering of community antenna television and radio distribution systems equipment installed in an information technology equipment room.

#### 645.4 Special Requirements for Information Technology Equipment Room

This article shall be permitted to provide alternate wiring methods to the provisions of Chapters 1 through 4 for power wiring, 725.154 for signaling wiring, and 770.113(C) and Table 770.154(a) for optical fiber cabling when all of the following conditions are met:

- (1) Disconnecting means complying with 645.10 are provided.
- (2) A separate heating/ventilating/air-conditioning (HVAC) system is provided that is dedicated for information technology equipment use and is separated from other areas of occupancy. Any HVAC system that serves other occupancies shall be permitted to also serve the information technology equipment room if fire/smoke dampers are provided at the point of penetration of the room boundary. Such dampers shall operate on activation of smoke detectors and by operation of the disconnecting means required by 645.10.

Informational Note: For further information, see NFPA 75-2009, *Standard for the Protection of Information Technology Equipment*, Chapter 10, 10.1, 10.1.1, 10.1.2, and 10.1.3.

- (3) All information technology and communications equipment installed in the room is listed.

- (4) The room is occupied by, and accessible to, only those personnel needed for the maintenance and functional operation of the installed information technology equipment.

- (5) The room is separated from other occupancies by fire-resistant-rated walls, floors, and ceilings with protected openings.

Informational Note: For further information on room construction requirements, see NFPA 75-2009, *Standard for the Protection of Information Technology Equipment*, Chapter 5.

- (6) Only electrical equipment and wiring associated with the operation of the information technology room is installed in the room.

Informational Note: HVAC systems, communications systems, and monitoring systems such as telephone, fire alarm systems, security systems, water detection systems, and other related protective equipment are examples of equipment associated with the operation of the information technology room.

Use of the requirements in Article 645 is based on the assumption that construction of the information technology equipment (ITE) room complies with NFPA 75, *Standard for the Protection of Information Technology Equipment*. For those ITE rooms constructed in accordance with NFPA 75, Article 645 contains electrical installation requirements that are less stringent than the requirements in the first four chapters of the *Code*. Application of these provisions is contingent on the ITE room construction and equipment meeting all six provisions specified in 645.4. For example, the provisions for wiring installations in the space beneath the raised floor of an ITE room where that space is also used for environmental air are less stringent than those in Chapters 1 through 4 for that same type of space. The less restrictive provisions in Article 645 cannot be taken advantage of if any one of the conditions specified in 645.4 is absent. Mandatory application of Article 645 is typically determined by the designer or facility manager who wants to use the provisions of this article for the electrical installation in the information technology equipment room instead of the relevant requirements in Chapters 1 through 4.

#### 645.5 Supply Circuits and Interconnecting Cables

**(A) Branch-Circuit Conductors.** The branch-circuit conductors supplying one or more units of information technology equipment shall have an ampacity not less than 125 percent of the total connected load.

**(B) Power-Supply Cords.** Information technology equipment shall be permitted to be connected to a branch circuit by a power-supply cord.

- (1) Power-supply cords shall not exceed 4.5 m (15 ft).

Only the power-supply cords of information technology equipment are limited in length by this requirement. Interconnecting cables covered in 645.5(C) are not limited to 15 ft in length.

- (2) Power cords shall be listed and a type permitted for use on listed information technology equipment or shall be constructed of listed flexible cord and listed attachment plugs and cord connectors of a type permitted for information technology equipment.

**Informational Note:** One method of determining if cords are of a type permitted for the purpose is found in UL 60950-1-2007, *Safety of Information Technology Equipment - Safety - Part 1: General Requirements*.

**(C) Interconnecting Cables.** Separate information technology equipment units shall be permitted to be interconnected by means of listed cables and cable assemblies. The 4.5 m (15 ft) limitation in 645.5(B)(1) shall not apply to interconnecting cables.

**(D) Physical Protection.** Where exposed to physical damage, supply circuits and interconnecting cables shall be protected.

**(E) Under Raised Floors.** Power cables, communications cables, connecting cables, interconnecting cables, cord-and-plug connections, and receptacles associated with the information technology equipment shall be permitted under a raised floor, provided the following conditions are met:

- (1) The raised floor is of approved construction, and the area under the floor is accessible.
- (2) The branch-circuit supply conductors to receptacles or field-wired equipment are in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, electrical metallic tubing, electrical nonmetallic tubing, metal wireway, nonmetallic wireway, surface metal raceway with metal cover, nonmetallic surface raceway, flexible metal conduit, liquidtight flexible metal conduit, or liquidtight flexible nonmetallic conduit, Type MI cable, Type MC cable, or Type AC cable and associated metallic and nonmetallic boxes or enclosures. These supply conductors shall be installed in accordance with the requirements of 300.11.

Branch-circuit conductors installed under the raised floor of an ITE room using any of the wiring methods listed in

645.5(E)(2) are required to conform to the specific article for the wiring method used. In addition, Article 300 applies, except where modified by Article 645. For example, 300.11 requires raceways, cables, and boxes to be securely fastened in place, even though they are installed below a raised floor.

- (3) Supply cords of listed information technology equipment in accordance with 645.5(B).

Supply cords of ITE equipment are permitted to be run through holes in a raised floor to connect to receptacles located below the raised floor. Openings in a raised floor through which cords and cables are run must be made so the cords and cables are not subject to abrasion. This provision allowing cords through openings in a raised floor is a 90.3 amendment to the general prohibition of this practice found in 400.8.

- (4) Ventilation in the underfloor area is used for the information technology equipment room only, except as provided in 645.4(2). The ventilation system shall be so arranged, with approved smoke detection devices, that upon the detection of fire or products of combustion in the underfloor space, the circulation of air will cease.

The underfloor area of an ITE room is required to be provided with smoke detection device(s). Upon detection of smoke, the circulation of air in the underfloor area must be interrupted. The most common method of interrupting air circulation is to open the circuit that supplies power to the air circulation fan. In addition to causing cessation of air circulation in the underfloor area, the smoke detectors may provide other fire protection functions as part of a complete building fire alarm system. A ventilation system can serve the underfloor areas of an ITE room as well as other areas of a building if the ventilation system is equipped with the requisite smoke and fire dampers at the ITE room boundaries. These fire protection features isolate the underfloor area from other areas served by the ventilation system upon detection of smoke or activation of the ITE room disconnecting means.

- (5) Openings in raised floors for cords and cables protect cords and cables against abrasion and minimize the entrance of debris beneath the floor.
- (6) Cables, other than those covered in (E)(2) and (E)(3), and those complying with (E)(6)(a) or (E)(6)(b), shall be listed as Type DP cable having adequate fire-resistant

characteristics suitable for use under raised floors of an information technology equipment room.

a. Interconnecting cables enclosed in a raceway.

b. Cable type designations shown in Table 645.5 shall be permitted. Green, or green with one or more yellow stripes, insulated single-conductor cables, 4 AWG and larger, marked “for use in cable trays” or “for CT use” shall be permitted for equipment grounding.

**Informational Note:** One method of defining *fire resistance* is by establishing that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *fire resistance* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

**TABLE 645.5 Cable Types Permitted Under Raised Floors**

Article	Plenum	Riser	General Purpose
336			TC
725	CL2P & CL3P	CL2R & CL3R	CL2, CL3 & PLTC
727			ITC
760	NPLFP & FPLP	NPLFR & FPLR	NPLF & FPL
770	OFNP & OFCP	OFNR & OFCR	OFN & OFC
800	CMP	CMR	CM & CMG
820	CATVP	CATVR	CATV

Interconnecting cables used under raised floors (other than branch-circuit conductors) are required by 645.5(E)(6) to be listed as Type DP cables. Cables that pass the Vertical Tray Flame Test referenced in *UL Flame Exposure, Vertical Tray Flame Test* in ANSI/UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*; or the *Vertical Flame Test — Cables in Cable Trays* as described in CSA C22.2, No. 0.3-M-2001, *Test Method for Electrical Wires and Cables* (where not more than 4 ft 11 in. of cable is damaged during the CSA test), are permitted to be installed under raised floors of computer rooms. Type DP cables that satisfy these tests are also permitted under raised floors. This requirement does not apply to power-supply cords of ITE equipment that are installed beneath the raised floor in accordance with 645.5(B) and 645.5(E)(3).

**(F) Securing in Place.** Power cables; communications cables; connecting cables; interconnecting cables; and associated boxes, connectors, plugs, and receptacles that are listed as part of, or for, information technology equipment shall not be required to be secured in place.

**(G) Abandoned Supply Circuits and Interconnecting Cables.** The accessible portion of abandoned supply circuits and interconnecting cables shall be removed unless contained in a raceway.

**(H) Installed Supply Circuits and Interconnecting Cables Identified for Future Use.**

- (1) Supply circuits and interconnecting cables identified for future use shall be marked with a tag of sufficient durability to withstand the environment involved.
- (2) Supply circuit tags and interconnecting cable tags shall have the following information:
  - a. Date identified for future use
  - b. Date of intended use
  - c. Information relating to the intended future use

## 645.6 Cables Not in Information Technology Equipment Room

Cables extending beyond the information technology equipment room shall be subject to the applicable requirements of this *Code*.

**Informational Note:** For signaling circuits, refer to Article 725; for optical fiber cables and raceways, refer to Article 770; for communications circuits, refer to Article 800; for fire alarm systems, refer to Article 760; and for community antenna television (CATV) circuits, refer to Article 820.

## 645.10 Disconnecting Means

An approved means shall be provided to disconnect power to all electronic equipment in the information technology equipment room or in designated zones within the room. There shall also be a similar approved means to disconnect the power to all dedicated HVAC systems serving the room or designated zones and shall cause all required fire/smoke dampers to close. The disconnecting means shall be implemented by either (A) or (B).

*Exception:* Installations qualifying under the provisions of Article 685.

**(A) Remote Disconnect Controls.**

**(1)** Remote disconnect controls shall be located at approved locations readily accessible in case of fire to authorized personnel and emergency responders.

(2) The remote disconnect controls for the control of electronic equipment power and HVAC systems shall be grouped and identified. A single means to control both systems shall be permitted.

(3) Where multiple zones are created, each zone shall have an approved means to confine fire or products of combustion to within the zone.

(4) Additional means to prevent unintentional operation of remote disconnect controls shall be permitted.

Typically, the circuit supplying the information technology equipment and the circuit supplying the HVAC system will be controlled through separate disconnecting means. However, operation of these disconnecting means can be accomplished through the use of a single remote control, such as one pushbutton. The disconnecting means is required to disconnect the conductors of each circuit from their supply source and close all required fire/smoke dampers. (See the definition of *disconnecting means* in Article 100.) The disconnecting means is permitted to be remote-controlled switching devices, such as relays, with pushbutton stations at the principal exit doors. The actuation of the emergency pushbutton(s) is to be accomplished by pushing the button in, rather than pulling it out. The requirement recognizes that in an emergency situation the intuitive reaction to operating the control is to push, not pull, the button.

The requirements of 645.10(A) and those of 645.3(A) for sealing penetrations are intended to minimize the passage of smoke or fire to other parts of the building.

Informational Note: For further information, see NFPA 75-2009, *Standard for the Protection of Information Technology Equipment*.

**(B) Critical Operations Data Systems.** Remote disconnecting controls shall not be required for critical operations data systems when all of the following conditions are met:

See the commentary following the definition of critical operations data system in 645.2. Only those data systems that have been designated as being critical in function based on that definition are permitted to implement the provision for not installing the remote disconnect control covered in 645.10(A).

- (1) An approved procedure has been established and maintained for removing power and air movement within the room or zone.
- (2) Qualified personnel are continuously available to meet emergency responders and to advise them of disconnecting methods.

- (3) A smoke-sensing fire detection system is in place.

Informational Note: For further information, see NFPA 72-2010, *National Fire Alarm and Signaling Code*.

- (4) An approved fire suppression system suitable for the application is in place.
- (5) Cables installed under a raised floor, other than branch-circuit wiring and power cords installed in compliance with 645.5(D)(2) or (D)(3), or in compliance with 300.22(C), 725.154(A), 770.113(C) and Table 770.154(a), 800.113(C) and Table 800.154(a), or 820.113(C) and Table 820.154(a).

### 645.11 Uninterruptible Power Supplies (UPSs)

Except for installations and constructions covered in 645.11(1) or (2), UPS systems installed within the information technology equipment room, and their supply and output circuits, shall comply with 645.10. The disconnecting means shall also disconnect the battery from its load.

- (1) Installations qualifying under the provisions of Article 685
- (2) Power sources limited to 750 volt-amperes or less derived either from UPS equipment or from battery circuits integral to electronic equipment

### 645.15 Grounding

All exposed non-current-carrying metal parts of an information technology system shall be bonded to the equipment grounding conductor in accordance with Article 250 or shall be double insulated. Power systems derived within listed information technology equipment that supply information technology systems through receptacles or cable assemblies supplied as part of this equipment shall not be considered separately derived for the purpose of applying 250.30. Where signal reference structures are installed, they shall be bonded to the equipment grounding conductor provided for the information technology equipment.

The last sentence of 645.15 recognizes that properly bonded high-frequency signal reference structures provide additional safety measures.

Informational Note No. 1: The bonding requirements in the product standards governing this listed equipment ensure that it complies with Article 250.

Informational Note No. 2: Where isolated grounding-type receptacles are used, see 250.146(D) and 406.3(D).

### 645.16 Marking

Each unit of an information technology system supplied by a branch circuit shall be provided with a manufacturer's

nameplate, which shall also include the input power requirements for voltage, frequency, and maximum rated load in amperes.

### 645.17 Power Distribution Units

Power distribution units that are used for information technology equipment shall be permitted to have multiple panelboards within a single cabinet, if the power distribution unit is utilization equipment listed for information technology application.

Power distribution units (PDUs) are specialized electrical distribution equipment used to supply multiple bays of rack-mounted modules installed in an ITE room. Due to the large number of overcurrent protective devices used in this type of application, PDUs are built with multiple panelboards installed in a single cabinet.

### 645.25 Engineering Supervision

As an alternative to the feeder and service load calculations required by Parts III and IV of Article 220, feeder and service load calculations for new or existing loads shall be permitted to be used if performed by qualified persons under engineering supervision.

This provision permits an engineered alternative to the load calculations in Parts III and IV of Article 220. The loads associated with computer hardware vary based on the operating system and software being used. Therefore, identical pieces of ITE equipment installed in different facilities will each have a load based on how the equipment is being used and applied in each of the facilities. The engineered alternative provides for a customized load calculation based on how a facility or a specific industry applies its computer hardware.

## ARTICLE 647 Sensitive Electronic Equipment

### Contents

  - (D) Voltage Drop
- 647.5 Three-Phase Systems

### 647.6 Grounding

- (A) General
- (B) Grounding Conductors Required

### 647.7 Receptacles

- (A) General
- (B) Isolated Ground Receptacles

### 647.8 Lighting Equipment

- (A) Disconnecting Means
- (B) Luminaires
- (C) Screw-Shell

### 647.1 Scope

This article covers the installation and wiring of separately derived systems operating at 120 volts line-to-line and 60 volts to ground for sensitive electronic equipment.

The use of this type of supply system as a means to reduce objectionable noise and its adverse effect on the performance of electronic audio and video equipment has been recognized since the 1996 edition of the *Code*. Article 647 permits the use of this type of supply system for all commercial and industrial applications where sensitive audio/video or similar electronic equipment is used. Such systems can be used only under the close supervision of qualified individuals.

Unlike electrical distribution systems that supply lighting and appliance branch circuits, the supply systems covered by Article 647 are subject to mandatory voltage-drop requirements. The voltage-drop requirements are needed to ensure the operation of overcurrent devices to protect conductors and equipment supplied by these systems. Because the use of standard overcurrent devices and distribution equipment with higher voltage ratings is permitted, the impedance in circuits supplied by these systems under fault conditions is a primary concern, hence the mandatory voltage-drop requirement.

### 647.3 General

Use of a separately derived 120-volt single-phase 3-wire system with 60 volts on each of two ungrounded conductors to a grounded neutral conductor shall be permitted for the purpose of reducing objectionable noise in sensitive electronic equipment locations, provided the following conditions apply:

- (1) The system is installed only in commercial or industrial occupancies.
- (2) The system's use is restricted to areas under close supervision by qualified personnel.
- (3) All of the requirements in 647.4 through 647.8 are met.

### 647.4 Wiring Methods

**(A) Panelboards and Overcurrent Protection.** Use of standard single-phase panelboards and distribution equipment with a higher voltage rating shall be permitted. The system shall be clearly marked on the face of the panel or on the inside of the panel doors. Common trip two-pole circuit breakers or a combination two-pole fused disconnecting means that are identified for use at the system voltage shall be provided for both ungrounded conductors in all feeders and branch circuits. Branch circuits and feeders shall be provided with a means to simultaneously disconnect all ungrounded conductors.

Circuit breakers and fuses are acceptable means of providing overcurrent protection for technical power circuits. Additionally, all technical power feeder and branch circuits are required to be provided with a disconnecting means that simultaneously opens all ungrounded conductors of the circuit.

**(B) Junction Boxes.** All junction box covers shall be clearly marked to indicate the distribution panel and the system voltage.

**(C) Conductor Identification.** All feeders and branch-circuit conductors installed under this section shall be identified as to system at all splices and terminations by color, marking, tagging, or equally effective means. The means of identification shall be posted at each branch-circuit panelboard and at the disconnecting means for the building.

**(D) Voltage Drop.** The voltage drop on any branch circuit shall not exceed 1.5 percent. The combined voltage drop of feeder and branch-circuit conductors shall not exceed 2.5 percent.

**(1) Fixed Equipment.** The voltage drop on branch circuits supplying equipment connected using wiring methods in Chapter 3 shall not exceed 1.5 percent. The combined voltage drop of feeder and branch-circuit conductors shall not exceed 2.5 percent.

**(2) Cord-Connected Equipment.** The voltage drop on branch circuits supplying receptacles shall not exceed 1 percent. For the purposes of making this calculation, the load connected to the receptacle outlet shall be considered to be 50 percent of the branch-circuit rating. The combined voltage drop of feeder and branch-circuit conductors shall not exceed 2.0 percent.

Informational Note: The purpose of this provision is to limit voltage drop to 1.5 percent where portable cords may be used as a means of connecting equipment.

### 647.5 Three-Phase Systems

Where 3-phase power is supplied, a separately derived 6-phase “wye” system with 60 volts to ground installed under this article shall be configured as three separately derived 120-volt single-phase systems having a combined total of no more than six disconnects.

### 647.6 Grounding

**(A) General.** The system shall be grounded as provided in 250.30 as a separately derived single-phase, 3-wire system.

**(B) Grounding Conductors Required.** Permanently wired utilization equipment and receptacles shall be grounded by means of an equipment grounding conductor run with the circuit conductors to an equipment grounding bus prominently marked “Technical Equipment Ground” in the originating branch-circuit panelboard. The grounding bus shall be connected to the grounded conductor on the line side of the separately derived system’s disconnecting means. The grounding conductor shall not be smaller than that specified in Table 250.122 and run with the feeder conductors. The technical equipment grounding bus need not be bonded to the panelboard enclosure. Other grounding methods authorized elsewhere in this *Code* shall be permitted where the impedance of the grounding return path does not exceed the impedance of equipment grounding conductors sized and installed in accordance with this article.

Informational Note No. 1: See 250.122 for equipment grounding conductor sizing requirements where circuit conductors are adjusted in size to compensate for voltage drop.

Informational Note No. 2: These requirements limit the impedance of the ground fault path where only 60 volts apply to a fault condition instead of the usual 120 volts.

### 647.7 Receptacles

**(A) General.** Where receptacles are used as a means of connecting equipment, the following conditions shall be met:

- (1) All 15- and 20-ampere receptacles shall be GFCI protected.
- (2) All receptacle outlet strips, adapters, receptacle covers, and faceplates shall be marked with the following words or equivalent:

WARNING — TECHNICAL POWER

Do not connect to lighting equipment.

For electronic equipment use only.

60/120 V. 1ϕac

GFCI protected

- (3) A 125-volt, single-phase, 15- or 20-ampere-rated receptacle having one of its current-carrying poles connected to a grounded circuit conductor shall be located within 1.8 m (6 ft) of all permanently installed 15- or 20-ampere-rated 60/120-volt technical power-system receptacles.

- (4) All 125-volt receptacles used for 60/120-volt technical power shall have a unique configuration and be identified for use with this class of system.

*Exception: Receptacles and attachment plugs rated 125-volt, single-phase, 15- or 20-amperes, and that are identified for use with grounded circuit conductors, shall be permitted in machine rooms, control rooms, equipment rooms, equipment racks, and other similar locations that are restricted to use by qualified personnel.*

**(B) Isolated Ground Receptacles.** Isolated ground receptacles shall be permitted as described in 250.146(D); however, the branch-circuit equipment grounding conductor shall be terminated as required in 647.6(B).

### 647.8 Lighting Equipment

Lighting equipment installed under this article for the purpose of reducing electrical noise originating from lighting equipment shall meet the conditions of 647.8(A) through (C).

**(A) Disconnecting Means.** All luminaires connected to separately derived systems operating at 60 volts to ground, and associated control equipment if provided, shall have a disconnecting means that simultaneously opens all ungrounded conductors. The disconnecting means shall be located within sight of the luminaire or be capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted.

**(B) Luminaires.** All luminaires shall be permanently installed and listed for connection to a separately derived system at 120 volts line-to-line and 60 volts to ground.

**(C) Screw Shell.** Luminaires installed under this section shall not have an exposed lamp screw shell.

## ARTICLE 650 Pipe Organs

### Contents

- 650.1 Scope
- 650.3 Other Articles
  - (A) Electronic Organ Equipment
  - (B) Optical Fiber Cable
- 650.4 Source of Energy
- 650.5 Grounding
- 650.6 Conductors

- (A) Size
- (B) Insulation
- (C) Conductors to Be Cabled
- (D) Cable Covering
- 650.7 Installation of Conductors
- 650.8 Overcurrent Protection

### 650.1 Scope

This article covers those electrical circuits and parts of electrically operated pipe organs that are employed for the control of the sounding apparatus and keyboards.

### 650.3 Other Articles

**(A) Electronic Organ Equipment.** Installations of digital/analog-sampled sound production technology and associated audio signal processing, amplification, reproduction equipment, and wiring installed as part of a pipe organ shall be in accordance with Article 640.

The requirements in Article 640 are to be followed for electronic sound production, amplification, signal processing, and other sound reproduction circuits and equipment installed as part of a pipe organ.

**(B) Optical Fiber Cable.** Installations of optical fiber cables shall be in accordance with Parts I and V of Article 770.

### 650.4 Source of Energy

The source of power shall be a transformer-type rectifier, the dc potential of which shall not exceed 30 volts dc.

### 650.5 Grounding

The rectifier shall be bonded to the equipment grounding conductor according to the provisions in Article 250, Parts V, VI, VII, and VIII.

### 650.6 Conductors

Conductors shall comply with 650.6(A) through (D).

**(A) Size.** Conductors shall be not less than 28 AWG for electronic signal circuits and not less than 26 AWG for electromagnetic valve supply and the like. A main common-return conductor in the electromagnetic supply shall not be less than 14 AWG.

Note that 14 AWG wire is required only for a main common return conductor in the electromagnetic supply.

**(B) Insulation.** Conductors shall have thermoplastic or thermosetting insulation.

**(C) Conductors to Be Cabled.** Except for the common-return conductor and conductors inside the organ proper, the organ sections and the organ console conductors shall be cabled. The common-return conductors shall be permitted under an additional covering enclosing both cable and return conductor, or they shall be permitted as a separate conductor and shall be permitted to be in contact with the cable.

**(D) Cable Covering.** Each cable shall be provided with an outer covering, either overall or on each of any subassemblies of grouped conductors. Tape shall be permitted in place of a covering. Where not installed in metal raceway, the covering shall be resistant to flame spread, or the cable or each cable subassembly shall be covered with a closely wound listed fireproof tape.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical-wire) flame test in the ANSI/UL 1581-2001, *Reference Standard for Electrical Wires, Cables and Flexible Cords*.

### 650.7 Installation of Conductors

Cables shall be securely fastened in place and shall be permitted to be attached directly to the organ structure without insulating supports. Cables shall not be placed in contact with other conductors. Abandoned cables that are not terminated at equipment shall be identified with a tag.

Insulating supports are not required for cables directly attached to the pipe organ. However, measures must be taken to prevent contact between the organ cables and conductors of other systems.

### 650.8 Overcurrent Protection

Circuits shall be so arranged that 26 AWG and 28 AWG conductors shall be protected by an overcurrent device rated at not more than 6 amperes. Other conductor sizes shall be protected in accordance with their ampacity. A common return conductor shall not require overcurrent protection.

## I. General

### 660.1 Scope

This article covers all X-ray equipment operating at any frequency or voltage for industrial or other nonmedical or non-dental use.

Informational Note: See Article 517, Part V, for X-ray installations in health care facilities.

Nothing in this article shall be construed as specifying safeguards against the useful beam or stray X-ray radiation.

Informational Note No. 1: Radiation safety and performance requirements of several classes of X-ray equipment are regulated under Public Law 90-602 and are enforced by the Department of Health and Human Services.

Informational Note No. 2: In addition, information on radiation protection by the National Council on Radiation Protection and Measurements is published as *Reports of the National Council on Radiation Protection and Measurement*. These reports can be obtained from NCRP Publications, 7910 Woodmont Ave., Suite 1016, Bethesda, MD 20814.

Article 660 covers X-ray equipment in industrial facilities or similar locations, where it is commonly used for inspecting a process or product. This method permits nondestructive testing without dismantling or applying stress to detect cracks, flaws, or structural defects. Welded joints are frequently inspected with X-ray equipment to detect hidden defects that can cause failure under stress.

Among the industrial applications of X-rays, the most common is radiography, in which shadow pictures of the object are produced on photographic film. The type and thickness of the material involved govern the voltage to be employed, which can range from a few thousand volts (kilovolts) to millions of volts (megavolts). It is possible to X-ray metal objects that are 20 in. thick.

Fluoroscopy is another X-ray technique used for industrial and commercial applications. Fluoroscopy is similar to radiography, but it operates at a much lower voltage range (less than 250 kilovolts). Instead of producing a film, it projects a shadow picture on a screen, similar to those used for security checks of luggage at airport terminals. Fluoroscopy is capable of detecting minute flaws or defects.

## 660.2 Definitions

**Long-Time Rating.** A rating based on an operating interval of 5 minutes or longer.

**Mobile.** X-ray equipment mounted on a permanent base with wheels and/or casters for moving while completely assembled.

**Momentary Rating.** A rating based on an operating interval that does not exceed 5 seconds.

**Portable.** X-ray equipment designed to be hand-carried.

**Transportable.** X-ray equipment that is to be installed in a vehicle or that may be readily disassembled for transport in a vehicle.

## 660.3 Hazardous (Classified) Locations

Unless identified for the location, X-ray and related equipment shall not be installed or operated in hazardous (classified) locations.

Informational Note: See Article 517, Part IV.

## 660.4 Connection to Supply Circuit

**(A) Fixed and Stationary Equipment.** Fixed and stationary X-ray equipment shall be connected to the power supply by means of a wiring method meeting the general requirements of this *Code*. Equipment properly supplied by a branch circuit rated at not over 30 amperes shall be permitted to be supplied through a suitable attachment plug cap and hard-service cable or cord.

## **(B) Portable, Mobile, and Transportable Equipment.**

Individual branch circuits shall not be required for portable, mobile, and transportable X-ray equipment requiring a capacity of not over 60 amperes. Portable and mobile types of X-ray equipment of any capacity shall be supplied through a suitable hard-service cable or cord. Transportable X-ray equipment of any capacity shall be permitted to be connected to its power supply by suitable connections and hard-service cable or cord.

**(C) Over 600 Volts, Nominal.** Circuits and equipment operated at more than 600 volts, nominal, shall comply with Article 490.

## 660.5 Disconnecting Means

A disconnecting means of adequate capacity for at least 50 percent of the input required for the momentary rating, or 100 percent of the input required for the long-time rating, of the X-ray equipment, whichever is greater, shall be provided in the supply circuit. The disconnecting means shall be operable from a location readily accessible from the X-ray control. For equipment connected to a 120-volt, nominal, branch circuit of 30 amperes or less, a grounding-type attachment plug cap and receptacle of proper rating shall be permitted to serve as a disconnecting means.

## 660.6 Rating of Supply Conductors and Overcurrent Protection

**(A) Branch-Circuit Conductors.** The ampacity of supply branch-circuit conductors and the overcurrent protective devices shall not be less than 50 percent of the momentary rating or 100 percent of the long-time rating, whichever is greater.

**(B) Feeder Conductors.** The rated ampacity of conductors and overcurrent devices of a feeder for two or more branch circuits supplying X-ray units shall not be less than 100 percent of the momentary demand rating [as determined by 660.6(A)] of the two largest X-ray apparatus plus 20 percent of the momentary ratings of other X-ray apparatus.

Informational Note: The minimum conductor size for branch and feeder circuits is also governed by voltage regulation requirements. For a specific installation, the manufacturer usually specifies minimum distribution transformer and conductor sizes, rating of disconnect means, and overcurrent protection.

## 660.7 Wiring Terminals

X-ray equipment not provided with a permanently attached cord or cord set shall be provided with suitable wiring terminals or leads for the connection of power-supply conductors of the size required by the rating of the branch circuit for the equipment.

### 660.9 Minimum Size of Conductors

Size 18 AWG or 16 AWG fixture wires, as specified in 725.49, and flexible cords shall be permitted for the control and operating circuits of X-ray and auxiliary equipment where protected by not larger than 20-ampere overcurrent devices.

### 660.10 Equipment Installations

All equipment for new X-ray installations and all used or reconditioned X-ray equipment moved to and reinstalled at a new location shall be of an approved type.

## II. Control

### 660.20 Fixed and Stationary Equipment

**(A) Separate Control Device.** A separate control device, in addition to the disconnecting means, shall be incorporated in the X-ray control supply or in the primary circuit to the high-voltage transformer. This device shall be a part of the X-ray equipment but shall be permitted in a separate enclosure immediately adjacent to the X-ray control unit.

**(B) Protective Device.** A protective device, which shall be permitted to be incorporated into the separate control device, shall be provided to control the load resulting from failures in the high-voltage circuit.

### 660.21 Portable and Mobile Equipment

Portable and mobile equipment shall comply with 660.20, but the manually controlled device shall be located in or on the equipment.

### 660.23 Industrial and Commercial Laboratory Equipment

**(A) Radiographic and Fluoroscopic Types.** All radiographic- and fluoroscopic-type equipment shall be effectively enclosed or shall have interlocks that de-energize the equipment automatically to prevent ready access to live current-carrying parts.

**(B) Diffraction and Irradiation Types.** Diffraction- and irradiation-type equipment or installations not effectively enclosed or not provided with interlocks to prevent access to uninsulated live parts during operation shall be provided with a positive means to indicate when they are energized. The indicator shall be a pilot light, readable meter deflection, or equivalent means.

### 660.24 Independent Control

Where more than one piece of equipment is operated from the same high-voltage circuit, each piece or each group of equipment as a unit shall be provided with a high-voltage

switch or equivalent disconnecting means. This disconnecting means shall be constructed, enclosed, or located so as to avoid contact by persons with its live parts.

A control device provides means for initiating and terminating X-ray exposures and automatically times their duration.

## III. Transformers and Capacitors

### 660.35 General

Transformers and capacitors that are part of an X-ray equipment shall not be required to comply with Articles 450 and 460.

High-ratio step-up transformers that are an integral part of an X-ray are not required to comply with Article 450 and are generally used to provide the high voltage necessary for X-ray tubes. Because there is a lesser degree of fire hazard due to the low primary voltage, X-ray transformers are not required to be installed in fire-resistant vaults.

### 660.36 Capacitors

Capacitors shall be mounted within enclosures of insulating material or grounded metal.

## IV. Guarding and Grounding

### 660.47 General

**(A) High-Voltage Parts.** All high-voltage parts, including X-ray tubes, shall be mounted within grounded enclosures. Air, oil, gas, or other suitable insulating media shall be used to insulate the high voltage from the grounded enclosure. The connection from the high-voltage equipment to X-ray tubes and other high-voltage components shall be made with high-voltage shielded cables.

**(B) Low-Voltage Cables.** Low-voltage cables connecting to oil-filled units that are not completely sealed, such as transformers, condensers, oil coolers, and high-voltage switches, shall have insulation of the oil-resistant type.

### 660.48 Grounding

Non-current-carrying metal parts of X-ray and associated equipment (controls, tables, X-ray tube supports, transformer tanks, shielded cables, X-ray tube heads, and so forth) shall be grounded in the manner specified in Article 250. Portable and mobile equipment shall be provided with an approved grounding-type attachment plug cap.

*Exception: Battery-operated equipment.*

Grounded enclosures are required to be provided for all high-voltage X-ray equipment, including X-ray tubes. High-voltage shielded cables are required to be used to connect high-voltage equipment to X-ray tubes, and the shield is required to be grounded, as specified in 660.48.

#### I. General

##### 665.1 Scope

This article covers the construction and installation of dielectric heating, induction heating, induction melting, and induction welding equipment and accessories for industrial and scientific applications. Medical or dental applications, appliances, or line frequency pipeline and vessel heating are not covered in this article.

Informational Note: See Article 427, Part V, for line frequency induction heating of pipelines and vessels.

To prevent spurious radiation caused by induction and dielectric heating equipment and to ensure that the frequency

spectrum is utilized equitably, the Federal Communications Commission (FCC) has established rules that govern the use of this type of industrial heating equipment operating above 10 kHz (FCC, 47 CFR 18).

For further information on electric heating systems using an induction heater or a dielectric heater in ovens and furnaces, see NFPA 86, *Standard for Ovens and Furnaces*.

#### 665.2 Definitions

**Converting Device.** That part of the heating equipment that converts input mechanical or electrical energy to the voltage, current, and frequency suitable for the heating applicator. A converting device shall consist of equipment using mains frequency, all static multipliers, oscillator-type units using vacuum tubes, inverters using solid-state devices, or motor generator equipment.

**Dielectric Heating.** Heating of a nominally insulating material due to its own dielectric losses when the material is placed in a varying electric field.

**Heating Equipment.** As used in this article, any equipment that is used for heating purposes and whose heat is generated by induction or dielectric methods.

**Heating Equipment Applicator.** The device used to transfer energy between the output circuit and the object or mass to be heated.

**Induction Heating, Melting, and Welding.** The heating, melting, or welding of a nominally conductive material due to its own  $I^2R$  losses when the material is placed in a varying electromagnetic field.

Induction and dielectric heating are used for ovens, furnaces, and industrial equipment where pieces of material are heated by a rapidly alternating magnetic or electric field.

#### Theory of Operation — Solid-State Converter Power Circuit

A solid-state power converter consists of three sections: the rectifier section, the inverter section, and the output section, which includes the load coil and is usually located outside the power supply. Exhibit 665.1 is an example of an enclosed power supply for an induction heating process. There are two basic types of inverters: voltage fed and current fed.

The rectifier section converts 3-phase, line frequency voltage to direct current. The input voltage can be any desired voltage — 480 volts, 575 volts, and 1150 volts are some typical voltages. The dc output is filtered with either a large choke (current-fed inverter) or a filter capacitor (voltage-fed inverter). The output of the rectifier section supplies energy for the inverter section. The inverter section converts

**EXHIBIT 665.1** Enclosed power supply for an induction heating process. (Courtesy of Ajax Tocco Magnethermic, Park Ohio Industries)

the energy stored in the magnetic field of the choke (current-fed inverter) or in the electric field of the filter capacitor (voltage-fed inverter) to a variable frequency for the output circuit. The variable output frequency controls the power delivered to the load.

The output section consists of a capacitor in parallel (current fed) or in series (voltage fed) with the coil. Because the output capacitance and coil inductance have a resonant frequency, as the output frequency approaches this resonant frequency, the power to the load approaches the maximum output. At minimum frequency, the output power is very low.

### Induction Heating

Induction heating occurs when an electrically conductive material (the load) is placed in a varying magnetic field. The magnetic field is generated by a coil (inductor) around or adjacent to the workpiece to be heated. The varying magnetic field induces current in the electrically conductive load. Heat in the load is generated by the resulting  $I^2R$  losses in the load. Induction heating can be further subdivided into heating, melting, and welding.

Induction heating raises the temperature of the load to some temperature below its melting point, usually for the purposes of hardening, tempering, annealing, forging, extruding, or rolling. Frequencies used for induction heating range from about 50 Hz to 500 kHz. Power levels range from 5 kW to 42,000 kW.

Induction melting raises the temperature of the load to some temperature above its melting point, so the molten material can be alloyed, homogenized, and/or poured. Frequencies used for induction melting range from about 50 Hz to 10 kHz. Power levels range from 5 kW to 16,500 kW.

Induction welding is primarily used in the manufacture of welded pipe and tubing. In this process, a high-frequency current is passed through an induction coil in the proximity of the conducting metal surfaces to be joined. By proper arrangement of the coil and by the addition of ferrite elements to control the currents induced in the surfaces, selected portions are heated nearly instantaneously to the forging temperature. The surfaces are then joined under pressure to produce a forge weld. Frequencies used for induction welding range from about 100 kHz to 800 kHz. Power levels range from 20 kW to 1000 kW. Induction heating (or melting or welding) of magnetic loads, such as iron or carbon steel, must contend with the change in magnetic permeability when the temperature of the load material passes its Curie temperature (at which point the load changes from the magnetic to the nonmagnetic state). The solid-state converter varies its output frequency to maintain constant output power through the entire range of temperatures of the load. Exhibit 665.2 shows an induction welding machine used in the manufacture of pipe and tubing.

**EXHIBIT 665.2** A solid-state induction welding machine. (Courtesy of Thermatool Corp.)

### Dielectric Heating

Dielectric heating equipment is similar to induction heating equipment, except that it is used to heat nonmetallic materials as opposed to metals. Typical applications include the drying of textiles after dyeing, drying of water-based coatings on paper, preheating of wood fibers for the medium-density fiberboard (MDF) industry, welding of plastic materials, food processing, and many other diverse applications.

At radio frequencies, the material to be heated forms a lossy dielectric when placed between metal capacitor plates connected across the output of the generator. A high-frequency alternating electric field is created between the electrode plates. The molecules in the dielectric field are made to vibrate, causing dissipation of energy through the material and frictional heating of the dielectric material.

At higher (microwave) frequencies, the process is similar, but the generator is coupled to a resonant cavity into which the dielectric material is placed.

The frequency of operation of dielectric heating equipment is considerably higher than for induction heating. By international agreement, these machines operate at the assigned radio frequencies of 13.56 MHz, 27.12 MHz, and 40.68 MHz or at microwave frequencies of 915 MHz and 2450 MHz.

All industrial dielectric heating equipment should meet appropriate U.S. federal regulations for radio frequency (RF) emissions (FCC, 47 CFR 18) and occupational safety (OSHA, 29 CFR 1910.97).

The majority of installed machines use vacuum tube generators, and powers range from 0.5 kW to 1 MW. Solid-state generators also have been installed, although powers have been limited to 5 kW or less.

If the load (the object or mass being heated) accidentally comes in contact with the output coil, a voltage to ground will appear on the load, depending on the various impedances to ground of the coil and the load. If the voltage on the load is limited to less than 50 volts, guarding per 110.27(A) is not required. If the coil is isolated from ground and the load is grounded through an impedance that is low (less than 1 percent) relative to the coil impedance to ground, the voltage of the load to ground will be low no matter where the load contacts the coil.

In induction melting furnaces, an additional reason for isolating the coil from ground is to limit the fault current when a coil does go to ground. Limiting the fault current is intended to prevent severe damage to the water-cooled coil, resulting in a water leak and the potential for a water–molten metal explosion. If water is trapped under molten metal, the rapid transfer of heat to the water causes the water to turn almost instantly into steam. The resulting 1600-to-1 expansion of the steam results in the ejection of molten metal from the furnace.

### 665.7 Remote Control

**(A) Multiple Control Points.** Where multiple control points are used for applicator energization, a means shall be provided and interlocked so that the applicator can be energized from only one control point at a time. A means for de-energizing the applicator shall be provided at each control point.

**(B) Foot Switches.** Switches operated by foot pressure shall be provided with a shield over the contact button to avoid accidental closing of a foot switch.

### 665.10 Ampacity of Supply Conductors

The ampacity of supply conductors shall be determined by 665.10(A) or (B).

**(A) Nameplate Rating.** The ampacity of conductors supplying one or more pieces of equipment shall be not less than the sum of the nameplate ratings for the largest group of machines capable of simultaneous operation, plus 100 percent of the standby currents of the remaining machines. Where standby currents are not given on the nameplate, the nameplate rating shall be used as the standby current.

**(B) Motor-Generator Equipment.** The ampacity of supply conductors for motor-generator equipment shall be determined in accordance with Article 430, Part II.

### 665.11 Overcurrent Protection

Overcurrent protection for the heating equipment shall be provided as specified in Article 240. This overcurrent

### 665.4 Hazardous (Classified) Locations

Heating equipment shall not be installed in hazardous (classified) locations as defined in Article 500 unless the equipment and wiring are designed and approved for the hazardous (classified) locations.

### 665.5 Output Circuit

The output circuit shall include all output components external to the converting device, including contactors, switches, busbars, and other conductors. The current flow from the output circuit to ground under operating and ground-fault conditions shall be limited to a value that does not cause 50 volts or more to ground to appear on any accessible part of the heating equipment and its load. The output circuit shall be permitted to be isolated from ground.

protection shall be permitted to be provided separately or as a part of the equipment.

### 665.12 Disconnecting Means

A readily accessible disconnecting means shall be provided to disconnect each heating equipment from its supply circuit. The disconnecting means shall be located within sight from the controller or be capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. Portable means for adding a lock to the switch or circuit breaker shall not be permitted.

The rating of this disconnecting means shall not be less than the nameplate rating of the heating equipment. Motor-generator equipment shall comply with Article 430, Part IX. The supply circuit disconnecting means shall be permitted to serve as the heating equipment disconnecting means where only one heating equipment is supplied.

## II. Guarding, Grounding, and Labeling

### 665.19 Component Interconnection

The interconnection components required for a complete heating equipment installation shall be guarded.

### 665.20 Enclosures

The converting device (excluding the component interconnections) shall be completely contained within an enclosure(s) of noncombustible material.

### 665.21 Control Panels

All control panels shall be of dead-front construction.

### 665.22 Access to Internal Equipment

Access doors or detachable access panels shall be employed for internal access to heating equipment. Access doors to internal compartments containing equipment employing voltages from 150 volts to 1000 volts ac or dc shall be capable of being locked closed or shall be interlocked to prevent the supply circuit from being energized while the door(s) is open. The provision for locking or adding a lock to the access doors shall be installed on or at the access door and shall remain in place with or without the lock installed.

Access doors to internal compartments containing equipment employing voltages exceeding 1000 volts ac or dc shall be provided with a disconnecting means equipped with mechanical lockouts to prevent access while the heating equipment is energized, or the access doors shall be capable of being locked closed and interlocked to prevent the supply circuit from being energized while the door(s) is open. Detachable panels not normally used for access to

such parts shall be fastened in a manner that makes them inconvenient to remove.

### 665.23 Warning Labels or Signs

Warning labels or signs that read “DANGER — HIGH VOLTAGE — KEEP OUT” shall be attached to the equipment and shall be plainly visible where persons might come in contact with energized parts when doors are open or closed or when panels are removed from compartments containing over 150 volts ac or dc.

### 665.24 Capacitors

The time and means of discharge shall be in accordance with 460.6 for capacitors rated 600 volts, nominal, and under. The time and means of discharge shall be in accordance with 460.28 for capacitors rated over 600 volts, nominal. Capacitor internal pressure switches connected to a circuit-interrupter device shall be permitted for capacitor overcurrent protection.

Note that enhanced protection against rupture of capacitor cases is necessary when capacitors are operated at the higher frequencies used for induction and dielectric heating. A high-resistance fault condition can cause case pressure to build up inside the capacitor over a very short time. Capacitor internal pressure switches are the preferred method to detect this type of failure.

Consider a 5000-kVAR, 2500-V, 300-Hz capacitor. Nominal current is 2000 amperes. A “high-resistance” fault of 10 ohms results in 250 amperes of resistive current, or a total capacitor current of 2016 amperes rms. This small increase in rms current will not result in the opening of an overcurrent device even though 625 kW of thermal energy is being generated inside the capacitor, which is designed to dissipate about 1.5 kW of losses.

### 665.25 Dielectric Heating Applicator Shielding

Protective cages or adequate shielding shall be used to guard dielectric heating applicators. Interlock switches shall be used on all hinged access doors, sliding panels, or other easy means of access to the applicator. All interlock switches shall be connected in such a manner as to remove all power from the applicator when any one of the access doors or panels is open.

### 665.26 Grounding and Bonding

Bonding to the equipment grounding conductor or inter-unit bonding, or both, shall be used wherever required for circuit operation, and for limiting to a safe value radio frequency voltages between all exposed non-current-carrying parts of the equipment and earth ground, between all equipment parts and surrounding objects, and between such objects and

earth ground. Such connection to the equipment grounding conductor and bonding shall be installed in accordance with Article 250, Parts II and V.

**Informational Note:** Under certain conditions, contact between the object being heated and the applicator results in an unsafe condition, such as eruption of heated materials. This unsafe condition may be prevented by grounding of the object being heated and ground detection.

Because of stray currents between units of equipment or to the ground, bonding presents special problems at radio frequencies. Special bonding requirements are particularly needed at dielectric heating frequencies (100 to 200 MHz) because of the differences in radio frequency potential that can exist between the equipment and surrounding metal units or other units of the installation. Satisfactory bonding can be accomplished by placing all units of the equipment on a flooring or base consisting of a copper or aluminum sheet, then thoroughly bonding by soldering, welding, or bolting. Such special bonding holds the radio frequency resistance and reactance between units to a minimum, and any stray circulating currents flowing through the bonding will not cause a dangerous voltage drop.

Protecting the operator from high radio frequency potentials by shielding at dielectric heating frequencies is necessary. Interference with radio communications systems at such high frequencies can be eliminated by totally enclosing all components in a shielding of copper or aluminum.

### 665.27 Marking

Each heating equipment shall be provided with a nameplate giving the manufacturer's name and model identification and the following input data: line volts, frequency, number of phases, maximum current, full-load kilovolt-amperes (kVA), and full-load power factor. Additional data shall be permitted.

### 668.1 Scope

The provisions of this article apply to the installation of the electrical components and accessory equipment of electrolytic cells, electrolytic cell lines, and process power supply for the production of aluminum, cadmium, chlorine, copper, fluorine, hydrogen peroxide, magnesium, sodium, sodium chlorate, and zinc.

Not covered by this article are cells used as a source of electric energy and for electroplating processes and cells used for the production of hydrogen.

**Informational Note No. 1:** In general, any cell line or group of cell lines operated as a unit for the production of a

particular metal, gas, or chemical compound may differ from any other cell lines producing the same product because of variations in the particular raw materials used, output capacity, use of proprietary methods or process practices, or other modifying factors to the extent that detailed *Code* requirements become overly restrictive and do not accomplish the stated purpose of this *Code*.

Informational Note No. 2: For further information, see IEEE 463-1993, *Standard for Electrical Safety Practices in Electrolytic Cell Line Working Zones*.

Within a cell line working zone, both an electrolytic cell line and its dc process power-supply circuit are treated as an individual machine supplied from a single source, even though they might cover acres of space, have a load current in excess of 400,000 amperes dc, or have a circuit voltage in excess of 1000 volts dc. The cell line process current passes through each cell in a series connection, and the load current cannot be subdivided, as it can in the heating circuit of a resistance-type electric furnace. Because a cell line is supplied by its individual dc rectifier system, the rectifier or the entire cell line circuit is de-energized by removing its source of primary power.

In some electrolytic cell systems, the terminal voltage of the process supply can be appreciable. The voltage to ground of exposed live parts from one end of a cell line to the other is variable between the limits of the terminal voltage. Hence, operating and maintenance personnel and their tools are required to be insulated from ground. See Exhibit 668.1 for an example of a pot room in an aluminum reduction plant.

## 668.2 Definitions

**Cell Line.** An assembly of electrically interconnected electrolytic cells supplied by a source of direct-current power.

**Cell Line Attachments and Auxiliary Equipment.** As applied to this article, a term that includes, but is not limited to, auxiliary tanks; process piping; ductwork; structural supports; exposed cell line conductors; conduits and other raceways; pumps, positioning equipment, and cell cutout or bypass electrical devices. Auxiliary equipment includes tools, welding machines, crucibles, and other portable equipment used for operation and maintenance within the electrolytic cell line working zone.

In the cell line working zone, auxiliary equipment includes the exposed conductive surfaces of ungrounded cranes and crane-mounted cell-servicing equipment.

**Electrically Connected.** A connection capable of carrying current as distinguished from connection through electromagnetic induction.

**Electrolytic Cell.** A tank or vat in which electrochemical reactions are caused by applying electric energy for the purpose of refining or producing usable materials.

**Electrolytic Cell Line Working Zone.** The space envelope wherein operation or maintenance is normally performed on or in the vicinity of exposed energized surfaces of electrolytic cell lines or their attachments.

**EXHIBIT 668.1** A typical pot room in an aluminum reduction plant. (Courtesy of Alcoa Inc.)

### 668.3 Other Articles

(A) **Lighting, Ventilating, Material Handling.** Chapters 1 through 4 shall apply to services, feeders, branch circuits, and apparatus for supplying lighting, ventilating, material handling, and the like that are outside the electrolytic cell line working zone.

(B) **Systems Not Electrically Connected.** Those elements of a cell line power-supply system that are not electrically connected to the cell supply system, such as the primary winding of a two-winding transformer, the motor of a motor-generator set, feeders, branch circuits, disconnecting means, motor controllers, and overload protective equipment, shall be required to comply with all applicable provisions of this *Code*.

(C) **Electrolytic Cell Lines.** Electrolytic cell lines shall comply with the provisions of Chapters 1 through 4 except as amended in 668.3(C)(1) through (C)(4).

(1) **Conductors.** The electrolytic cell line conductors shall not be required to comply with the provisions of Articles 110, 210, 215, 220, and 225. See 668.11.

(2) **Overcurrent Protection.** Overcurrent protection of electrolytic cell dc process power circuits shall not be required to comply with the requirements of Article 240.

(3) **Grounding.** Equipment located or used within the electrolytic cell line working zone or associated with the cell line direct-current power circuits shall not be required to comply with the provisions of Article 250.

(4) **Working Zone.** The electrolytic cells, cell line attachments, and the wiring of auxiliary equipment and devices within the cell line working zone shall not be required to comply with the provisions of Articles 110, 210, 215, 220, and 225. See 668.30.

Informational Note: See 668.15 for equipment, apparatus, and structural component grounding.

### 668.10 Cell Line Working Zone

(A) **Area Covered.** The space envelope of the cell line working zone shall encompass spaces that meet any of the following conditions:

- (1) Is within 2.5 m (96 in.) above energized surfaces of electrolytic cell lines or their energized attachments
- (2) Is below energized surfaces of electrolytic cell lines or their energized attachments, provided the headroom in the space beneath is less than 2.5 m (96 in.)
- (3) Is within 1.0 m (42 in.) horizontally from energized surfaces of electrolytic cell lines or their energized attachments

ments or from the space envelope described in 668.10(A)(1) or (A)(2)

(B) **Area Not Covered.** The cell line working zone shall not be required to extend through or beyond walls, floors, roofs, partitions, barriers, or the like.

### 668.11 Direct-Current Cell Line Process Power Supply

(A) **Not Grounded.** The direct-current cell line process power-supply conductors shall not be required to be grounded.

(B) **Metal Enclosures Grounded.** All metal enclosures of power-supply apparatus for the direct-current cell line process operating at a power-supply potential between terminals of over 50 volts shall be grounded by either of the following means:

- (1) Through protective relaying equipment
- (2) By a minimum 2/0 AWG copper grounding conductor or a conductor of equal or greater conductance

(C) **Grounding Requirements.** The grounding connections required by 668.11(B) shall be installed in accordance with 250.8, 250.10, 250.12, 250.68, and 250.70.

### 668.12 Cell Line Conductors

(A) **Insulation and Material.** Cell line conductors shall be either bare, covered, or insulated and of copper, aluminum, copper-clad aluminum, steel, or other suitable material.

(B) **Size.** Cell line conductors shall be of such cross-sectional area that the temperature rise under maximum load conditions and at maximum ambient shall not exceed the safe operating temperature of the conductor insulation or the material of the conductor supports.

(C) **Connections.** Cell line conductors shall be joined by bolted, welded, clamped, or compression connectors.

### 668.13 Disconnecting Means

(A) **More Than One Process Power Supply.** Where more than one direct-current cell line process power supply serves the same cell line, a disconnecting means shall be provided on the cell line circuit side of each power supply to disconnect it from the cell line circuit.

(B) **Removable Links or Conductors.** Removable links or removable conductors shall be permitted to be used as the disconnecting means.

### 668.14 Shunting Means

**(A) Partial or Total Shunting.** Partial or total shunting of cell line circuit current around one or more cells shall be permitted.

**(B) Shunting One or More Cells.** The conductors, switches, or combination of conductors and switches used for shunting one or more cells shall comply with the applicable requirements of 668.12.

### 668.15 Grounding

For equipment, apparatus, and structural components that are required to be grounded by provisions of Article 668, the provisions of Article 250 shall apply, except a water pipe electrode shall not be required to be used. Any electrode or combination of electrodes described in 250.52 shall be permitted.

### 668.20 Portable Electrical Equipment

**(A) Portable Electrical Equipment Not to Be Grounded.** The frames and enclosures of portable electrical equipment used within the cell line working zone shall not be grounded.

*Exception No. 1: Where the cell line voltage does not exceed 200 volts dc, these frames and enclosures shall be permitted to be grounded.*

*Exception No. 2: These frames and enclosures shall be permitted to be grounded where guarded.*

**(B) Isolating Transformers.** Electrically powered, hand-held, cord-connected portable equipment with ungrounded frames or enclosures used within the cell line working zone shall be connected to receptacle circuits that have only ungrounded conductors such as a branch circuit supplied by an isolating transformer with an ungrounded secondary.

**(C) Marking.** Ungrounded portable electrical equipment shall be distinctively marked and shall employ plugs and receptacles of a configuration that prevents connection of this equipment to grounding receptacles and that prevents inadvertent interchange of ungrounded and grounded portable electrical equipments.

### 668.21 Power-Supply Circuits and Receptacles for Portable Electrical Equipment

**(A) Isolated Circuits.** Circuits supplying power to ungrounded receptacles for hand-held, cord-connected equipment shall be electrically isolated from any distribution system supplying areas other than the cell line working zone and shall be ungrounded. Power for these circuits shall be supplied through isolating transformers. Primaries of such transformers shall operate at not more than 600 volts between conductors and shall be provided with proper overcur-

rent protection. The secondary voltage of such transformers shall not exceed 300 volts between conductors, and all circuits supplied from such secondaries shall be ungrounded and shall have an approved overcurrent device of proper rating in each conductor.

**(B) Noninterchangeability.** Receptacles and their mating plugs for ungrounded equipment shall not have provision for a grounding conductor and shall be of a configuration that prevents their use for equipment required to be grounded.

**(C) Marking.** Receptacles on circuits supplied by an isolating transformer with an ungrounded secondary shall be a distinctive configuration, shall be distinctively marked, and shall not be used in any other location in the plant.

### 668.30 Fixed and Portable Electrical Equipment

**(A) Electrical Equipment Not Required to Be Grounded.** Alternating-current systems supplying fixed and portable electrical equipment within the cell line working zone shall not be required to be grounded.

**(B) Exposed Conductive Surfaces Not Required to Be Grounded.** Exposed conductive surfaces, such as electrical equipment housings, cabinets, boxes, motors, raceways, and the like, that are within the cell line working zone shall not be required to be grounded.

**(C) Wiring Methods.** Auxiliary electrical equipment such as motors, transducers, sensors, control devices, and alarms, mounted on an electrolytic cell or other energized surface, shall be connected to premises wiring systems by any of the following means:

- (1) Multiconductor hard usage cord.
- (2) Wire or cable in suitable raceways or metal or nonmetallic cable trays. If metal conduit, cable tray, armored cable, or similar metallic systems are used, they shall be installed with insulating breaks such that they do not cause a potentially hazardous electrical condition.

**(D) Circuit Protection.** Circuit protection shall not be required for control and instrumentation that are totally within the cell line working zone.

**(E) Bonding.** Bonding of fixed electrical equipment to the energized conductive surfaces of the cell line, its attachments, or auxiliaries shall be permitted. Where fixed electrical equipment is mounted on an energized conductive surface, it shall be bonded to that surface.

### 668.31 Auxiliary Nonelectrical Connections

Auxiliary nonelectrical connections, such as air hoses, water hoses, and the like, to an electrolytic cell, its attachments, or

auxiliary equipment shall not have continuous conductive reinforcing wire, armor, braids, and the like. Hoses shall be of a nonconductive material.

### 668.32 Cranes and Hoists

**(A) Conductive Surfaces to Be Insulated from Ground.** The conductive surfaces of cranes and hoists that enter the cell line working zone shall not be required to be grounded. The portion of an overhead crane or hoist that contacts an energized electrolytic cell or energized attachments shall be insulated from ground.

**(B) Hazardous Electrical Conditions.** Remote crane or hoist controls that could introduce hazardous electrical conditions into the cell line working zone shall employ one or more of the following systems:

- (1) Isolated and ungrounded control circuit in accordance with 668.21(A)
- (2) Nonconductive rope operator
- (3) Pendant pushbutton with nonconductive supporting means and having nonconductive surfaces or ungrounded exposed conductive surfaces
- (4) Radio

### 668.40 Enclosures

General-purpose electrical equipment enclosures shall be permitted where a natural draft ventilation system prevents the accumulation of gases.

## ARTICLE 669 Electroplating

### Contents

- 669.1 Scope
- 669.3 General
- 669.5 Branch-Circuit Conductors
- 669.6 Wiring Methods
  - (A) Systems Not Exceeding 50 Volts Direct Current
  - (B) Systems Exceeding 50 Volts Direct Current
- 669.7 Warning Signs
- 669.8 Disconnecting Means
  - (A) More Than One Power Supply
  - (B) Removable Links or Conductors
- 669.9 Overcurrent Protection

### 669.1 Scope

The provisions of this article apply to the installation of the electrical components and accessory equipment that supply the power and controls for electroplating, anodizing, electropolishing, and electrostripping. For purposes of this arti-

cle, the term *electroplating* shall be used to identify any or all of these processes.

Because of the extremely high currents and low voltages normally involved, conventional wiring methods cannot be used in electroplating, anodizing, electropolishing, and electrostripping processes. Sections 669.6(A) and (B) permit the use of bare conductors, even in systems exceeding 50 volts dc. Some systems in the aluminum anodizing process have potentials up to 240 volts. Warning signs are required to be posted to indicate the presence of bare conductors.

### 669.3 General

Equipment for use in electroplating processes shall be identified for such service.

### 669.5 Branch-Circuit Conductors

Branch-circuit conductors supplying one or more units of equipment shall have an ampacity of not less than 125 percent of the total connected load. The ampacities for busbars shall be in accordance with 366.23.

### 669.6 Wiring Methods

Conductors connecting the electrolyte tank equipment to the conversion equipment shall be in accordance with 669.6(A) and (B).

**(A) Systems Not Exceeding 50 Volts Direct Current.** Insulated conductors shall be permitted to be run without insulated support, provided they are protected from physical damage. Bare copper or aluminum conductors shall be permitted where supported on insulators.

**(B) Systems Exceeding 50 Volts Direct Current.** Insulated conductors shall be permitted to be run on insulated supports, provided they are protected from physical damage. Bare copper or aluminum conductors shall be permitted where supported on insulators and guarded against accidental contact up to the point of termination in accordance with 110.27.

### 669.7 Warning Signs

Warning signs shall be posted to indicate the presence of bare conductors.

### 669.8 Disconnecting Means

**(A) More Than One Power Supply.** Where more than one power supply serves the same dc system, a disconnecting means shall be provided on the dc side of each power supply.

**(B) Removable Links or Conductors.** Removable links or removable conductors shall be permitted to be used as the disconnecting means.

### 669.9 Overcurrent Protection

Direct-current conductors shall be protected from overcurrent by one or more of the following:

- (1) Fuses or circuit breakers
- (2) A current-sensing device that operates a disconnecting means
- (3) Other approved means

- 670.5 Short-Circuit Current Rating

### 670.1 Scope

This article covers the definition of, the nameplate data for, and the size and overcurrent protection of supply conductors to industrial machinery.

Informational Note No. 1: For further information, see NFPA 79-2007, *Electrical Standard for Industrial Machinery*.

The requirements of Article 670 cover the power-supply circuit from the building or structure wiring system to the disconnecting means of an industrial machine. The equipment and wiring of industrial machinery, for which different component parts may be purchased and assembled at the location of use, must be installed in accordance with the applicable articles in the *NEC*. Machinery assembled by the manufacturer, in accordance with NFPA 79, *Electrical Standard for Industrial Machinery*, then disassembled for shipping and reassembled at its place of use, comes only under Article 670 and any *NEC* sections referenced herein. In this case, the machinery is treated as a package unit.

The information to be included on the nameplate of an industrial machine is specified in this article. This informa-

tion allows for proper conductor sizing, overcurrent protection of the feeder or branch circuit supplying the machine, and integration of the machine into the facility electrical system.

Informational Note No. 2: For information on the workspace requirements for equipment containing supply conductor terminals, see 110.26. For information on the workspace requirements for machine power and control equipment, see NFPA 79-2007, *Electrical Standard for Industrial Machinery*.

Working clearances around control equipment enclosures and compartments containing equipment operating at 600 volts or less, that are an integral part of an industrial machine, are contained in Section 11.5 in NFPA 79-2007, *Electrical Standard for Industrial Machinery*. The requirements in this section of NFPA 79 closely parallel those found in 110.26(A), but there are provisions in NFPA 79 that allow smaller clearances under very specific conditions of operation and equipment construction.

### 670.2 Definition

**Industrial Machinery (Machine).** A power-driven machine (or a group of machines working together in a coordinated manner), not portable by hand while working, that is used to process material by cutting; forming; pressure; electrical, thermal, or optical techniques; lamination; or a combination of these processes. It can include associated equipment used to transfer material or tooling, including fixtures, to assemble/disassemble, to inspect or test, or to package. [The associated electrical equipment, including the logic controller(s) and associated software or logic together with the machine actuators and sensors, are considered as part of the industrial machine.]

Exhibit 670.1 shows an example of an industrial machine. The scope of Article 670, described in 670.1, and the definitions in 670.2 permit the inclusion of other types of industrial machines without the need to continuously modify the scope of Article 670 and NFPA 79, *Electrical Standard for Industrial Machinery*. Also, the scope and definition are more in harmony with NFPA 79 and IEC 60204-1, *Safety of Machinery — Electrical Equipment of Machines — Part 1: General Requirements*.

### 670.3 Machine Nameplate Data

**(A) Permanent Nameplate.** A permanent nameplate shall be attached to the control equipment enclosure or machine and shall be plainly visible after installation. The nameplate shall include the following information:

**EXHIBIT 670.1** All-electric injection molding machine with programmable controller-based control. (Courtesy of Milacron)

- (1) Supply voltage, number of phases, frequency, and full-load current
- (2) Maximum ampere rating of the short-circuit and ground-fault protective device
- (3) Ampere rating of largest motor, from the motor nameplate, or load
- (4) Short-circuit current rating of the machine industrial control panel based on one of the following:
  - a. Short-circuit current rating of a listed and labeled machine control enclosure or assembly
  - b. Short-circuit current rating established utilizing an approved method

Informational Note: UL 508A-2001, Supplement SB, is an example of an approved method.

- (5) Electrical diagram number(s) or the number of the index to the electrical drawings

The full-load current shown on the nameplate shall not be less than the sum of the full-load currents required for all motors and other equipment that may be in operation at the same time under normal conditions of use. Where unusual type loads, duty cycles, and so forth require oversized conductors or permit reduced-size conductors, the required capacity shall be included in the marked “full-load current.” Where more than one incoming supply circuit is to be provided, the nameplate shall state the preceding information for each circuit.

An industrial machine’s nameplate must provide the short-circuit current rating of the machine’s industrial control panel. That rating is established either by the rating determined as part of the listing of the control enclosure or assembly or, for assemblies that are not listed, by an

proved method of determining the short-circuit current rating.

Based on the *NEC* definition of *approved*, such a method is one that is acceptable to the authority having jurisdiction. In the absence of product listing, Supplement SB to UL 508A, *Standard for Industrial Control Panels*, is referred to as one example of a method for determining the short-circuit current rating of a control panel or assembly that could be used as a basis for equipment approval.

The second paragraph of 670.3(A) recognizes that the operating characteristics of an industrial machine may permit the use of a feeder demand factor, as covered in 430.26. An industrial machine containing motors sized for high torque but in normal operation run at close to no-load current values is an example of where it may be appropriate to reduce the full-load current marking on the machine nameplate.

Informational Note: See 430.22(E) and 430.26 for duty cycle requirements.

**(B) Overcurrent Protection.** Where overcurrent protection is provided in accordance with 670.4(B), the machine shall be marked “overcurrent protection provided at machine supply terminals.”

## 670.4 Supply Conductors and Overcurrent Protection

**(A) Size.** The size of the supply conductor shall be such as to have an ampacity not less than 125 percent of the full-load current rating of all resistance heating loads plus 125 percent of the full-load current rating of the highest rated motor plus the sum of the full-load current ratings of all other connected motors and apparatus, based on their duty cycle, that may be in operation at the same time.

The requirements in 670.4(A) for determining the minimum ampacity of a supply circuit conductor for an industrial machine reference the duty cycle of motors and apparatus as a consideration. Depending on the operating characteristics of the motor, the duty cycle of the apparatus might not always result in reduction of the supply conductor ampacity. Where motors are used in other than a continuous-duty mode of operation, Table 430.22(E) provides percentages by which the full-load current (FLC) of a given motor is increased or decreased for the purpose of sizing motor circuit conductors. A motor that is loaded continuously under any conditions of use is regarded to be a continuous-duty application.

Informational Note No. 1: See the 0–2000-volt ampacity tables of Article 310 for ampacity of conductors rated 600 volts and below.

Informational Note No. 2: See 430.22(E) and 430.26 for duty cycle requirements.

**(B) Disconnecting Means.** A machine shall be considered as an individual unit and therefore shall be provided with disconnecting means. The disconnecting means shall be permitted to be supplied by branch circuits protected by either fuses or circuit breakers. The disconnecting means shall not be required to incorporate overcurrent protection.

In regard to the machine disconnecting means, NFPA 79-2007, *Electrical Standard for Industrial Machinery*, states, in part:

The center of the grip of the operating handle of the disconnecting means, when in its highest position, shall be not more than 2.0 m (6 ft 7 in.) above the servicing level. A permanent operating platform, readily accessible by means of a permanent stair or ladder, shall be considered the servicing level for the purpose of this requirement.

[The device shall] be provided with a permanent means permitting it to be locked in the off (open) position only (e.g., by padlocks) independent of the door position. When so locked, remote as well as local closing shall be prevented. [NFPA 79-2007, 5.3.4.1 and 5.3.3.1]

**(C) Overcurrent Protection.** Where furnished as part of the machine, overcurrent protection for each supply circuit shall consist of a single circuit breaker or set of fuses, the machine shall bear the marking required in 670.3, and the supply conductors shall be considered either as feeders or as taps as covered by 240.21.

The rating or setting of the overcurrent protective device for the circuit supplying the machine shall not be greater than the sum of the largest rating or setting of the branch-circuit short-circuit and ground-fault protective device provided with the machine, plus 125 percent of the full-load current rating of all resistance heating loads, plus the sum of the full-load currents of all other motors and apparatus that could be in operation at the same time.

*Exception: Where one or more instantaneous trip circuit breakers or motor short-circuit protectors are used for motor branch-circuit short-circuit and ground-fault protection as permitted by 430.52(C), the procedure specified in 670.4(C) for determining the maximum rating of the protective device for the circuit supplying the machine shall apply with the following provision: For the purpose of the calculation, each instantaneous trip circuit breaker or motor short-circuit protector shall be assumed to have a rating not exceeding the maximum percentage of motor full-load current permitted by Table 430.52 for the type of machine supply circuit protective device employed.*

Where no branch-circuit short-circuit and ground-fault protective device is provided with the machine, the rating or setting of the overcurrent protective device shall be based on 430.52 and 430.53, as applicable.

The nameplate provides the necessary information to size the branch-circuit or feeder conductors, the machine disconnecting means, and overcurrent protection. The computation of motor and nonmotor loads is reflected on the nameplate as full-load amperes, and no further calculation is necessary. Sizing of circuit conductors and overcurrent protection beyond the machine disconnecting means is under the scope of NFPA 79.

## 670.5 Short-Circuit Current Rating

Industrial machinery shall not be installed where the available fault current exceeds its short-circuit current rating as marked in accordance with 670.3(A)(4).

This requirement clarifies that it is the marked short-circuit current rating (SCCR) specified by 670.3(A)(4) and not the interrupting or SCCR of individual circuit components within the machinery control panel(s) that is to be used in determining compliance with this section and with 110.9 and 110.10.

#### I. General

##### 675.1 Scope

The provisions of this article apply to electrically driven or controlled irrigation machines, and to the branch circuits and controllers for such equipment.

Electric pump motors used to supply water to irrigation machines are governed by the general requirements of the *NEC*, not by Article 675.

##### 675.2 Definitions

**Center Pivot Irrigation Machine.** A multimotored irrigation machine that revolves around a central pivot and employs alignment switches or similar devices to control individual motors.

**Collector Rings.** An assembly of slip rings for transferring electric energy from a stationary to a rotating member.

**Irrigation Machine.** An electrically driven or controlled machine, with one or more motors, not hand-portable, and used primarily to transport and distribute water for agricultural purposes.

##### 675.4 Irrigation Cable

**(A) Construction.** The cable used to interconnect enclosures on the structure of an irrigation machine shall be an assembly of stranded, insulated conductors with nonhygroscopic and nonwicking filler in a core of moisture- and flame-resistant nonmetallic material overlaid with a metallic covering and jacketed with a moisture-, corrosion-, and sunlight-resistant nonmetallic material.

The conductor insulation shall be of a type listed in Table 310.104(A) for an operating temperature of 75°C (167°F) and for use in wet locations. The core insulating material thickness shall not be less than 0.76 mm (30 mils), and the metallic overlay thickness shall be not less than 0.20 mm (8 mils). The jacketing material thickness shall be not less than 1.27 mm (50 mils).

A composite of power, control, and grounding conductors in the cable shall be permitted.

**(B) Alternate Wiring Methods.** Installation of other listed cables complying with the construction requirements of 675.4(A) shall be permitted.

**(C) Supports.** Irrigation cable shall be secured by straps, hangers, or similar fittings identified for the purpose and so installed as not to damage the cable. Cable shall be supported at intervals not exceeding 1.2 m (4 ft).

**(D) Fittings.** Fittings shall be used at all points where irrigation cable terminates. The fittings shall be designed for use with the cable and shall be suitable for the conditions of service.

### 675.5 More Than Three Conductors in a Raceway or Cable

The signal and control conductors of a raceway or cable shall not be counted for the purpose of ampacity adjustment as required in 310.15(B)(3)(a).

### 675.6 Marking on Main Control Panel

The main control panel shall be provided with a nameplate that shall give the following information:

- (1) The manufacturer's name, the rated voltage, the phase, and the frequency
- (2) The current rating of the machine
- (3) The rating of the main disconnecting means and size of overcurrent protection required

### 675.7 Equivalent Current Ratings

Where intermittent duty is not involved, the provisions of Article 430 shall be used for determining ratings for controllers, disconnecting means, conductors, and the like. Where irrigation machines have inherent intermittent duty, the determinations of equivalent current ratings in 675.7(A) and (B) shall be used.

**(A) Continuous-Current Rating.** The equivalent continuous-current rating for the selection of branch-circuit conductors and overcurrent protection shall be equal to 125 percent of the motor nameplate full-load current rating of the largest motor, plus a quantity equal to the sum of each of the motor nameplate full-load current ratings of all remaining motors on the circuit, multiplied by the maximum percent duty cycle at which they can continuously operate.

**(B) Locked-Rotor Current.** The equivalent locked-rotor current rating shall be equal to the numerical sum of the locked-rotor current of the two largest motors plus 100 percent of the sum of the motor nameplate full-load current ratings of all the remaining motors on the circuit.

### 675.8 Disconnecting Means

**(A) Main Controller.** A controller that is used to start and stop the complete machine shall meet all of the following requirements:

- (1) An equivalent continuous current rating not less than specified in 675.7(A) or 675.22(A)
- (2) A horsepower rating not less than the value from Table 430.251(A) and Table 430.251(B), based on the equivalent locked-rotor current specified in 675.7(B) or 675.22(B)

*Exception:* A listed molded case switch shall not require a horsepower rating.

A molded case switch used as a motor controller is not required to have a horsepower rating, but it is required to have a continuous current (ampere) rating not less than that specified by 675.7(A) or 675.22(A).

**(B) Main Disconnecting Means.** The main disconnecting means for the machine shall provide overcurrent protection, shall be at the point of connection of electric power to the machine, or shall be visible and not more than 15 m (50 ft) from the machine, and shall be readily accessible and capable of being locked in the open position. The provision for locking or adding a lock to the disconnecting means shall be installed on or at the switch or circuit breaker used as the disconnecting means and shall remain in place with or without the lock installed. This disconnecting means shall have a horsepower and current rating not less than required for the main controller.

In accordance with 675.8(B), the main disconnecting means is permitted to be up to 50 ft from the machine but must be readily accessible and capable of being locked in the open position. This eliminates one set of overcurrent protective devices and one disconnecting means where the circuit originates at the motor control panel for the irrigation pump and the panel is located within 50 ft of the center pivot machine. It also alleviates some potential problems with machines designed to be towed to a second site.

*Exception No. 1:* Circuit breakers without marked horsepower ratings shall be permitted in accordance with 430.109.

*Exception No. 2:* A listed molded case switch without marked horsepower ratings shall be permitted.

**(C) Disconnecting Means for Individual Motors and Controllers.** A disconnecting means shall be provided to simultaneously disconnect all ungrounded conductors for each motor and controller and shall be located as required by Article 430, Part IX. The disconnecting means shall not be required to be readily accessible.

Article 430, Part IX, provides for safety during maintenance and inspection shutdown periods. See the commentary following 430.103.

### 675.9 Branch-Circuit Conductors

The branch-circuit conductors shall have an ampacity not less than specified in 675.7(A) or 675.22(A).

### 675.10 Several Motors on One Branch Circuit

**(A) Protection Required.** Several motors, each not exceeding 2 hp rating, shall be permitted to be used on an irrigation machine circuit protected at not more than 30 amperes at 600 volts, nominal, or less, provided all of the following conditions are met:

- (1) The full-load rating of any motor in the circuit shall not exceed 6 amperes.
- (2) Each motor in the circuit shall have individual overload protection in accordance with 430.32.
- (3) Taps to individual motors shall not be smaller than 14 AWG copper and not more than 7.5 m (25 ft) in length.

The requirements of 430.53 provide for motor branch-circuit short-circuit and ground-fault protection where several motors are supplied by one branch circuit. A combination of these requirements, which are modified for this special equipment application, is found in 675.10.

**(B) Individual Protection Not Required.** Individual branch-circuit short-circuit protection for motors and motor controllers shall not be required where the requirements of 675.10(A) are met.

### 675.11 Collector Rings

**(A) Transmitting Current for Power Purposes.** Collector rings shall have a current rating not less than 125 percent of the full-load current of the largest device served plus the full-load current of all other devices served, or as determined from 675.7(A) or 675.22(A).

**(B) Control and Signal Purposes.** Collector rings for control and signal purposes shall have a current rating not less than 125 percent of the full-load current of the largest device served plus the full-load current of all other devices served.

**(C) Grounding.** The collector ring used for grounding shall have a current rating not less than that sized in accordance with 675.11(A).

**(D) Protection.** Collector rings shall be protected from the expected environment and from accidental contact by means of a suitable enclosure.

### 675.12 Grounding

The following equipment shall be grounded:

- (1) All electrical equipment on the irrigation machine
- (2) All electrical equipment associated with the irrigation machine

- (3) Metal junction boxes and enclosures
- (4) Control panels or control equipment that supplies or controls electrical equipment to the irrigation machine

*Exception: Grounding shall not be required on machines where all of the following provisions are met:*

- (a) *The machine is electrically controlled but not electrically driven.*
- (b) *The control voltage is 30 volts or less.*
- (c) *The control or signal circuits are current limited as specified in Chapter 9, Tables 11(A) and 11(B).*

### 675.13 Methods of Grounding

Machines that require grounding shall have a non-current-carrying equipment grounding conductor provided as an integral part of each cord, cable, or raceway. This grounding conductor shall be sized not less than the largest supply conductor in each cord, cable, or raceway. Feeder circuits supplying power to irrigation machines shall have an equipment grounding conductor sized according to Table 250.122.

### 675.14 Bonding

Where electrical grounding is required on an irrigation machine, the metallic structure of the machine, metallic conduit, or metallic sheath of cable shall be connected to the grounding conductor. Metal-to-metal contact with a part that is connected to the grounding conductor and the non-current-carrying parts of the machine shall be considered as an acceptable bonding path.

### 675.15 Lightning Protection

If an irrigation machine has a stationary point, a grounding electrode system in accordance with Article 250, Part III, shall be connected to the machine at the stationary point for lightning protection.

Where the electrical power supply to irrigation machine equipment is a service, the requirements of Article 250 for grounding the system and equipment are applicable. Due to the physical location of irrigation equipment, the most likely grounding electrode of the types covered in 250.52 is a driven ground rod or ground plate. Consideration should be given to the requirements of 250.60 and NFPA 780, *Standard for the Installation of Lightning Protection Systems*, in areas where lightning protection is critical. A common electrode system is not permitted to be used for the dual function of grounding the electric service and grounding the lightning protection system. The separate electrode systems are required to be bonded together.

### 675.16 Energy from More Than One Source

Equipment within an enclosure receiving electric energy from more than one source shall not be required to have a disconnecting means for the additional source, provided that its voltage is 30 volts or less and it meets the requirements of Part III of Article 725.

### 675.17 Connectors

External plugs and connectors on the equipment shall be of the weatherproof type.

Unless provided solely for the connection of circuits meeting the requirements of Part III of Article 725, external plugs and connectors shall be constructed as specified in 250.124(A).

## II. Center Pivot Irrigation Machines

### 675.21 General

The provisions of Part II are intended to cover additional special requirements that are peculiar to center pivot irrigation machines. See 675.2 for the definition of *Center Pivot Irrigation Machine*.

### 675.22 Equivalent Current Ratings

To establish ratings of controllers, disconnecting means, conductors, and the like, for the inherent intermittent duty of center pivot irrigation machines, the determinations in 675.22(A) and (B) shall be used.

The ratings of electrical components of any circuit should be selected so as to avoid extensive damage to the equipment during a short circuit or ground fault. Requirements for establishing ratings of components of special equipment for inherent intermittent duty are covered in 675.22. Also see the commentary following 110.10 and 430.52.

**(A) Continuous-Current Rating.** The equivalent continuous-current rating for the selection of branch-circuit conductors and branch-circuit devices shall be equal to 125 percent of the motor nameplate full-load current rating of the largest motor plus 60 percent of the sum of the motor nameplate full-load current ratings of all remaining motors on the circuit.

**(B) Locked-Rotor Current.** The equivalent locked-rotor current rating shall be equal to the numerical sum of two times the locked-rotor current of the largest motor plus 80 percent of the sum of the motor nameplate full-load current ratings of all the remaining motors on the circuit.

## I. General

### 680.1 Scope

The provisions of this article apply to the construction and installation of electrical wiring for, and equipment in or adjacent to, all swimming, wading, therapeutic, and decorative pools; fountains; hot tubs; spas; and hydromassage bathtubs, whether permanently installed or storable, and to metallic auxiliary equipment, such as pumps, filters, and similar equipment. The term *body of water* used throughout Part I applies to all bodies of water covered in this scope unless otherwise amended.

Article 680 applies to decorative pools and fountains; swimming, wading, and wave pools; therapeutic tubs and tanks; hot tubs; spas; hydromassage bathtubs; and similar installations including pools used in religious services where participants are immersed in water. The installations covered by this article can be indoors or outdoors, permanent or storable, and may or may not be directly supplied by electrical circuits of any nature. Requirements for natural and artificially made bodies of water not covered by Article 680 are contained in Article 682.

Studies conducted by Underwriters Laboratories, various manufacturers, and others indicate that a person in a swimming pool can receive a severe electric shock by reaching out and touching the energized casing of a faulty appliance — such as a radio or a hair dryer — as the person's body, which due to immersion has a lower resistance to electric current, establishes a conductive path through the water to earth. Also, a person not in contact with a faulty appliance or any grounded object can receive an electric shock and be rendered immobile by a potential gradient in the water itself. This level of electrical current necessary to cause immobilization may not be fatal from an electrical shock perspective but is dangerous from an accidental drowning standpoint. Shock hazards in and around a swimming pool can result from faulty electrical equipment directly associated with the pool or from faulty electrical equipment not associated with but in close proximity to the pool.

Accordingly, the requirements of Article 680 covering effective bonding and grounding, installation of receptacles and luminaires, use of GFCIs, modified wiring methods, and so on, apply not only to the installation of the pool but also to installations and equipment adjacent to or associated with the pool.

Enhanced electric shock protection in this wet environment, where it is intended that people are immersed in bodies of water that also contain electrical equipment, is provided through one or more of the following means:

- GFCI protection and low-voltage equipment
- Double-insulated equipment
- Insulation and isolation
- Equipotential bonding
- Physical separation and restricted locations
- Robust physical protection requirements for circuit conductors

## 680.2 Definitions

**Cord-and-Plug-Connected Lighting Assembly.** A lighting assembly consisting of a luminaire intended for installation in the wall of a spa, hot tub, or storable pool, and a cord-and-plug-connected transformer.

**Dry-Niche Luminaire.** A luminaire intended for installation in the floor or wall of a pool, spa, or fountain in a niche that is sealed against the entry of water.

**Equipment, Fixed.** Equipment that is fastened or otherwise secured at a specific location.

**Equipment, Portable.** Equipment that is actually moved or can easily be moved from one place to another in normal use.

**Equipment, Stationary.** Equipment that is not easily moved from one place to another in normal use.

**Forming Shell.** A structure designed to support a wet-niche luminaire assembly and intended for mounting in a pool or fountain structure.

**Fountain.** Fountains, ornamental pools, display pools, and reflection pools. The definition does not include drinking fountains.

**Hydromassage Bathtub.** A permanently installed bathtub equipped with a recirculating piping system, pump, and associated equipment. It is designed so it can accept, circulate, and discharge water upon each use.

See the commentary following 680.71, 680.73, and 680.74 for more information on installation requirements for hydromassage bath tubs.

**Low Voltage Contact Limit.** A voltage not exceeding the following values:

- (1) 15 volts (RMS) for sinusoidal ac
- (2) 21.2 volts peak for nonsinusoidal ac
- (3) 30 volts for continuous dc
- (4) 12.4 volts peak for dc that is interrupted at a rate of 10 to 200 Hz

The *low voltage contact limits* described in this definition are based on the wet contact limits specified in Tables 11(A) and 11(B) in Chapter 9. In prior editions of the *Code*, the use of isolated winding type transformers that provided a sinusoidal ac voltage not exceeding 15 volts was used as the “low voltage” operational threshold for underwater luminaires. Although the 15-volt limit in Article 680 was based on a transformer-type power supply, it applied to all “low voltage” systems. Any luminaire operating at more than 15 volts was required to be protected by a ground-fault circuit interrupter.

In addition to sinusoidal alternating current, this definition also identifies the maximum acceptable safe levels for other voltage systems. Depending on the system, this maxi-

imum level is either higher or lower than that considered safe for sinusoidal ac voltage. New technologies for underwater lighting that integrate power supplies other than the traditional isolated winding type transformer have been developed, and this definition and associated requirements in Article 680 ensure that those new power supplies can be safely integrated into the swimming pool environment.

**Maximum Water Level.** The highest level that water can reach before it spills out.

The *maximum water level* is used as the benchmark for determining minimum distance between equipment such as luminaires or ceiling-suspended (paddle) fans and the water in a pool, spa, or hot tub. The maximum water level is also used in determining the clearance between overhead conductors and the pool water. The normal water level is used as the benchmark for determining location of underwater luminaires. Exhibit 680.1 illustrates the difference between the normal water level (typically controlled by the pool filtration system) and the *maximum water level*.

**EXHIBIT 680.1** Maximum water level — the point at which the water would spill out of the pool onto the perimeter surface surrounding the pool. Normal water level is used for determining the location of the underwater luminaire.

**No-Niche Luminaire.** A luminaire intended for installation above or below the water without a niche.

**Packaged Spa or Hot Tub Equipment Assembly.** A factory-fabricated unit consisting of water-circulating, heat-

ing, and control equipment mounted on a common base, intended to operate a spa or hot tub. Equipment can include pumps, air blowers, heaters, lights, controls, sanitizer generators, and so forth.

The definition of *packaged spa or hot tub equipment assembly* clarifies which assemblies are subject to the requirements of 680.44.

**Packaged Therapeutic Tub or Hydrotherapeutic Tank Equipment Assembly.** A factory-fabricated unit consisting of water-circulating, heating, and control equipment mounted on a common base, intended to operate a therapeutic tub or hydrotherapeutic tank. Equipment can include pumps, air blowers, heaters, lights, controls, sanitizer generators, and so forth.

**Permanently Installed Decorative Fountains and Reflection Pools.** Those that are constructed in the ground, on the ground, or in a building in such a manner that the fountain cannot be readily disassembled for storage, whether or not served by electrical circuits of any nature. These units are primarily constructed for their aesthetic value and are not intended for swimming or wading.

**Permanently Installed Swimming, Wading, Immersion, and Therapeutic Pools.** Those that are constructed in the ground or partially in the ground, and all others capable of holding water in a depth greater than 1.0 m (42 in.), and all pools installed inside of a building, regardless of water depth, whether or not served by electrical circuits of any nature.

The word *immersion* extends this definition to pools used in religious services or for some other function in which people become immersed as an inherent use or purpose of the pool. Also see the commentary following Part VI of Article 680 Pools and Tubs for Therapeutic Use.

**Pool.** Manufactured or field-constructed equipment designed to contain water on a permanent or semipermanent basis and used for swimming, wading, immersion, or therapeutic purposes.

**Pool Cover, Electrically Operated.** Motor-driven equipment designed to cover and uncover the water surface of a pool by means of a flexible sheet or rigid frame.

The requirements for electrically operated pool covers are contained in 680.27(B).

**Self-Contained Spa or Hot Tub.** Factory-fabricated unit consisting of a spa or hot tub vessel with all water-circulating, heating, and control equipment integral to the unit. Equipment can include pumps, air blowers, heaters, lights, controls, sanitizer generators, and so forth.

The definition of *self-contained spa or hot tub* clarifies which assemblies are subject to the requirements of 680.44.

**Self-Contained Therapeutic Tubs or Hydrotherapeutic Tanks.** A factory-fabricated unit consisting of a therapeutic tub or hydrotherapeutic tank with all water-circulating, heating, and control equipment integral to the unit. Equipment may include pumps, air blowers, heaters, light controls, sanitizer generators, and so forth.

**Spa or Hot Tub.** A hydromassage pool, or tub for recreational or therapeutic use, not located in health care facilities, designed for immersion of users, and usually having a filter, heater, and motor-driven blower. It may be installed indoors or outdoors, on the ground or supporting structure, or in the ground or supporting structure. Generally, a spa or hot tub is not designed or intended to have its contents drained or discharged after each use.

See the commentary following 680.41, 680.42, 680.43, and 680.44 for more information on installation of spas and hot tubs.

**Storable Swimming, Wading, or Immersion Pool.** Those that are constructed on or above the ground and are capable of holding water to a maximum depth of 1.0 m (42 in.), or a pool with nonmetallic, molded polymeric walls or inflatable fabric walls regardless of dimension.

See the commentary following 680.30 and Exhibit 680.12 for more information on the installation requirements for storable pools.

Originally, storable pools were not specifically addressed in the *NEC*. Article 680 was written to provide guidance relative to permanent, in-ground pools and their unique construction requirements because of the unusual earth–water–electricity–human body environment created in the finished product. The conductivity of moist concrete or metal walls buried in the ground, the incorporation of large masses of reinforcing steel, and the inclusion of stainless-steel handrails and diving-board stands, as well as 120-volt lights in the pool structure, all called for the strict wiring, bonding, and grounding requirements of Article 680.

Storable pools are intended to be temporary structures, without the need for special wiring or modification to the

pool site. They are usually sold as a complete package, consisting of the pool walls, vinyl liner, plumbing kit, and pump/filter device. A storable pool is often disassembled and stored during the winter months. Regional preferences, weather patterns, economic considerations, and design characteristics of the pool are all factors influencing this action.

Part III of Article 680 was created to address the special equipment specifications of storable pools, and Underwriters Laboratories developed testing and labeling criteria for listing the pump/filter units designed especially for these pools. This equipment has the following characteristics:

1. It must have an approved system of double insulation or the equivalent.
2. It is permitted to have a flexible cord equipped with a parallel-blade, grounding-type attachment plug for electrical connection.
3. It must have a grounding conductor included in the flexible cord.
4. The flexible cord is not limited to 3 ft, as required by 680.7(A), and is specified by UL to be not less than 25 ft long. This length was chosen to discourage the use of extension cords.

The UL labeling requirement for these listed units includes the wording “Do Not Use with Permanently Installed Pools.” In some cases, consumers and swimming pool installers, however, have found it desirable to use these pump/filter units on any aboveground or on-ground pool, regardless of the pool’s dimensions or “storability.”

Storable pools are supplied as two distinct types. One type is intended to be disassembled at the end of each swimming season. The second type, by the nature of its construction, can be disassembled, but manufacturers recommend leaving it assembled. The pools in the latter category frequently require special modification to and preparation of the pool site, making them impractical to disassemble. Draining these pools, especially the larger ones, increases the likelihood of costly damage caused by shrinkage of the vinyl liner material.

The main factor differentiating the two types of pools is wall height. Generally, pools, other than the inflatable type, intended to be disassembled at season’s end have wall heights of 42 in. or less, while those not intended for disassembly have wall heights of 48 in. or more. The surface area of the pools is not a factor. Inflatable pools are treated as storable pools regardless of their wall height.

**Through-Wall Lighting Assembly.** A lighting assembly intended for installation above grade, on or through the wall of a pool, consisting of two interconnected groups of components separated by the pool wall.

**Wet-Niche Luminaire.** A luminaire intended for installation in a forming shell mounted in a pool or fountain structure where the luminaire will be completely surrounded by water.

### 680.3 Other Articles

Except as modified by this article, wiring and equipment in or adjacent to pools and fountains shall comply with other applicable provisions of this *Code*, including those provisions identified in Table 680.3.

**TABLE 680.3 Other Articles**

Topic	Section or Article
Site lighting systems operating at 30 volts or less	411.4(B)
Audio equipment	Article 640, Parts I and II
Adjacent to pools and fountains	640.10
Underwater speakers*	

\*Underwater loudspeakers shall be installed in accordance with 680.27(A).

### 680.4 Approval of Equipment

All electrical equipment installed in the water, walls, or decks of pools, fountains, and similar installations shall comply with the provisions of this article.

### 680.5 Ground-Fault Circuit Interrupters

Ground-fault circuit interrupters (GFCIs) shall be self-contained units, circuit-breaker or receptacle types, or other listed types.

See the definition of *ground-fault circuit interrupter (GFCI)* in Article 100. A GFCI is intended to be used only in a circuit that has a solidly grounded conductor; however, an equipment grounding conductor is not necessary for the GFCI to function. A Class A GFCI trips where the current to ground has a value in the range of 4 through 6 mA; it is suitable for use in swimming pool circuits. It should be noted, however, that circuits supplying pool equipment, including underwater luminaires, that were installed before local adoption of the 1965 edition of the *Code* may have sufficient leakage current to cause a Class A GFCI to trip. A Class B GFCI trips if the current to ground exceeds 20 mA; it is suitable for use only with underwater swimming pool lighting installed before the local adoption of the 1965 *Code*.

### 680.6 Grounding

Electrical equipment shall be grounded in accordance with Parts V, VI, and VII of Article 250 and connected by wiring

methods of Chapter 3, except as modified by this article. The following equipment shall be grounded:

- (1) Through-wall lighting assemblies and underwater luminaires, other than those low-voltage lighting products listed for the application without a grounding conductor
- (2) All electrical equipment located within 1.5 m (5 ft) of the inside wall of the specified body of water
- (3) All electrical equipment associated with the recirculating system of the specified body of water
- (4) Junction boxes
- (5) Transformer and power supply enclosures
- (6) Ground-fault circuit interrupters
- (7) Panelboards that are not part of the service equipment and that supply any electrical equipment associated with the specified body of water

Electrical equipment other than underwater luminaires and pool-associated motors is required to be connected by the wiring methods of Chapter 3 and grounded in accordance with Article 250. For example, an outdoor receptacle installed to meet the requirements of 680.22(A)(3) is permitted to be wired with Type UF cable containing an insulated or bare conductor for equipment grounding purposes. Circuits for pools may be derived from an existing remote panelboard supplied by an approved cable assembly, as specified in 680.25(A), Exception. The requirements of 680.6 permit Type UF cable to be used for the receptacle required by 680.22(A)(3) and for some pool-related equipment, but circuit conductors for underwater luminaires are required to be run in raceways. Circuit conductors for pool-associated motors other than flexible cord, as permitted by 680.7, are required to be installed in raceways except in the interior of one-family dwelling units, where any raceway or cable assembly permitted by Chapter 3 is acceptable if the equipment grounding conductor is at least 12 AWG copper and is enclosed by the wiring method.

Equipment grounding requirements are contained in 680.6, 680.21(A)(1), 680.23(F)(2), and 680.25(B). These requirements specify that equipment grounding conductors be connected to non-current-carrying metal parts of the specified equipment. These equipment grounding conductors are required to be run with the circuit conductors in rigid metal conduit, intermediate conduit, listed MC cable (for motors only), or rigid nonmetallic conduit (electrical metallic tubing is permitted in or on buildings, and electrical nonmetallic tubing is permitted inside buildings), and they must be terminated at the grounding terminal bus of the service panelboard, the source of the separately derived system, or the subpanel. This equipment grounding conductor provides a path of low impedance that limits the voltage to ground and facilitates operation of the circuit overcurrent protective device(s). The equipment grounding conductor

is required to be an insulated copper conductor not smaller than 12 AWG.

The requirements of 680.6, 680.21(A)(1), 680.23(F)(2), and 680.25(B) are in addition to the bonding requirements in 680.26. The intent of the bonding requirements is to establish an equipotential plane to limit the voltage between all non-current-carrying parts of electrical and nonelectrical equipment in the pool area. Bonding conductors may be insulated, covered, or bare and are required to be 8 AWG solid copper or larger. The bonding conductors may be direct buried, and, if connected to metal parts of the pool structure or metal parts of electrical equipment, they may be externally clamped or attached and are not required to be accessible. All these parts form a common grid that establishes an equipotential bonding system, and the bonding conductors do not have to be run to the equipment grounding terminals of panelboards or service equipment.

680.7 Cord-and-Plug-Connected Equipment

Fixed or stationary equipment, other than underwater luminaires, for a permanently installed pool shall be permitted to be connected with a flexible cord and plug to facilitate the removal or disconnection for maintenance or repair.

(A) **Length.** For other than storable pools, the flexible cord shall not exceed 900 mm (3 ft) in length.

(B) **Equipment Grounding.** The flexible cord shall have a copper equipment grounding conductor sized in accordance with 250.122 but not smaller than 12 AWG. The cord shall terminate in a grounding-type attachment plug.

(C) **Construction.** The equipment grounding conductors shall be connected to a fixed metal part of the assembly. The

removable part shall be mounted on or bonded to the fixed metal part.

In some climates, it is preferable to disconnect and remove a permanent pool’s filter pump during cold-weather months. A 3-ft cord is permitted, to facilitate the removal of fixed or stationary equipment for maintenance and storage. The 3-ft cord limitation does not apply to cord-and-plug-connected filter pumps used with storable-type pools (covered in Part III of Article 680), since these pumps are neither fixed nor stationary. Listed filter pumps for use with storable pools are considered portable and are permitted to be equipped with cords longer than 3 ft.

680.8 Overhead Conductor Clearances

Overhead conductors shall meet the clearance requirements in this section. Where a minimum clearance from the water level is given, the measurement shall be taken from the maximum water level of the specified body of water.

(A) **Power.** With respect to service drop conductors and open overhead wiring, swimming pool and similar installations shall comply with the minimum clearances given in Table 680.8 and illustrated in Figure 680.8.

Informational Note: Open overhead wiring as used in this article typically refers to conductor(s) not in an enclosed raceway.

(B) **Communications Systems.** Communications, radio, and television coaxial cables within the scope of Articles 800 through 820 shall be permitted at a height of not less than 3.0 m (10 ft) above swimming and wading pools, diving structures, and observation stands, towers, or platforms.

TABLE 680.8 Overhead Conductor Clearances

Clearance Parameters		Insulated Cables, 0–750 Volts to Ground, Supported on and Cabled Together with a Solidly Grounded Bare Messenger or Solidly Grounded Neutral Conductor		All Other Conductors Voltage to Ground			
				0 through 15 kV		Over 15 through 50 kV	
		m	ft	m	ft	m	ft
A.	Clearance in any direction to the water level, edge of water surface, base of diving platform, or permanently anchored raft	6.9	22.5	7.5	25	8.0	27
B.	Clearance in any direction to the observation stand, tower, or diving platform	4.4	14.5	5.2	17	5.5	18
C.	Horizontal limit of clearance measured from inside wall of the pool	This limit shall extend to the outer edge of the structures listed in A and B of this table but not to less than 3 m (10 ft).					

**FIGURE 680.8** Clearances from Pool Structures

**(C) Network-Powered Broadband Communications Systems.** The minimum clearances for overhead network-powered broadband communications systems conductors from pools or fountains shall comply with the provisions in Table 680.8 for conductors operating at 0 to 750 volts to ground.

Service drop conductors, overhead service conductors, conductors of network-powered broadband communications systems, and aerial feeders and branch circuits are permitted to be located above a swimming pool and associated pool structures where provided with the clearances specified in Table 680.8. Overhead conductors of communications systems are required to comply with 680.8(B). These clearances consider such factors as the use of skimmers with aluminum handles and provide sufficient separation between the conductors and the pool. In some instances, locating a swimming pool below electric fixed conductors is unavoidable; for example, on a building lot with limited area or an existing lot where the electric supply lines are already in place.

The clearances for conductors from pools and pool structures harmonize the *NEC* with ANSI C2, *National Electrical Safety Code (NESC)*. The maximum water level of the body of water (pool, spa, hot tub, or other) is used to determine compliance with 680.8. For the definition of *maximum water level*, see 680.2.

### 680.9 Electric Pool Water Heaters

All electric pool water heaters shall have the heating elements subdivided into loads not exceeding 48 amperes and protected at not over 60 amperes. The ampacity of the branch-circuit conductors and the rating or setting of over-current protective devices shall not be less than 125 percent of the total nameplate-rated load.

### 680.10 Underground Wiring Location

Underground wiring shall not be permitted under the pool or within the area extending 1.5 m (5 ft) horizontally from the inside wall of the pool unless this wiring is necessary to sup-

ply pool equipment permitted by this article. Where space limitations prevent wiring from being routed a distance 1.5 m (5 ft) or more from the pool, such wiring shall be permitted where installed in complete raceway systems of rigid metal conduit, intermediate metal conduit, or a nonmetallic raceway system. All metal conduit shall be corrosion resistant and suitable for the location. The minimum cover depth shall be as given in Table 680.10.

**TABLE 680.10** Minimum Cover Depths

Wiring Method	Minimum Cover	
	mm	in.
Rigid metal conduit	150	6
Intermediate metal conduit	150	6
Nonmetallic raceways listed for direct burial under minimum of 102 mm (4 in.) thick concrete exterior slab and extending not less than 162 mm (6 in.) beyond the underground installation	150	6
Nonmetallic raceways listed for direct burial without concrete encasement	450	18
Other approved raceways*	450	18

\*Raceways approved for burial only where concrete encased shall require a concrete envelope not less than 50 mm (2 in.) thick

This section allows wiring within 5 ft of the inside walls of the swimming pool under two conditions. The first condition permits wiring to pool-associated equipment such as an underwater luminaire. The second condition permits wiring not associated with the pool within this area where spatial constraints such as property lines preclude the 5-ft minimum separation. Under the second condition, underground wiring located within the 5-ft zone is required to be installed in rigid metal conduit, intermediate metal conduit, or rigid nonmetallic conduit and must be buried to a depth not less than that required by Table 680.10 for these permitted wiring methods. The raceway must be installed as a complete system between points of termination and cannot simply be a sleeve through the 5-ft zone. Beyond the 5-ft zone, the minimum cover requirements of Table 300.5 apply to the underground wiring methods used for circuits rated 600 volts and less.

As indicated by the title of this section (Underground Wiring Location), the focus of 680.10 is to mitigate shock hazards that may occur as a result of a faulty or damaged underground installation that is in close proximity to the swimming pool. Due to water splashing out of the pool and water dripping off those who have been in the pool, the area within 5 ft of the inside walls is generally the wettest location; as a result, electrical leakage from underground installations presents a greater shock hazard in this continuously wet environment.

### 680.11 Equipment Rooms and Pits

Electrical equipment shall not be installed in rooms or pits that do not have drainage that adequately prevents water accumulation during normal operation or filter maintenance.

### 680.12 Maintenance Disconnecting Means

One or more means to simultaneously disconnect all ungrounded conductors shall be provided for all utilization equipment other than lighting. Each means shall be readily accessible and within sight from its equipment and shall be located at least 1.5 m (5 ft) horizontally from the inside walls of a pool, spa, or hot tub unless separated from the open water by a permanently installed barrier that provides a 1.5 m (5 ft) reach path or greater. This horizontal distance is to be measured from the water's edge along the shortest path required to reach the disconnect.

A readily accessible disconnecting means is required to be located within sight of pool, spa, and hot tub equipment in order to provide service personnel with the ability to safely disconnect power while servicing equipment such as motors, heaters, and control panels. Underwater luminaires are not subject to this requirement. The proximity of the disconnecting means to the pool must be not less than 5 ft unless the disconnecting means is separated from the water by a permanent barrier. See Exhibit 680.2.

**EXHIBIT 680.2** Required pool equipment disconnect, located within sight of the pool equipment (filter pump motor in this illustration) and at least 5 ft from the pool, in accordance with 680.12.

## II. Permanently Installed Pools

### 680.20 General

Electrical installations at permanently installed pools shall comply with the provisions of Part I and Part II of this article.

### 680.21 Motors

**(A) Wiring Methods.** The wiring to a pool motor shall comply with (A)(1) unless modified for specific circumstances by (A)(2), (A)(3), (A)(4), or (A)(5).

**(1) General.** The branch circuits for pool-associated motors shall be installed in rigid metal conduit, intermediate metal conduit, rigid polyvinyl chloride conduit, reinforced thermosetting resin conduit, or Type MC cable listed for the location. Other wiring methods and materials shall be permitted in specific locations or applications as covered in this section. Any wiring method employed shall contain an insulated copper equipment grounding conductor sized in accordance with 250.122 but not smaller than 12 AWG.

Type MC cable listed for the application is permitted as a wiring method for swimming pool motor circuits. This listing requirement ensures that the MC cable is suitable for the environmental and installation conditions typically encountered with swimming pool pump motors. Type MC cables listed for installation in direct sunlight or direct burial are marked to indicate suitability for such applications.

Other than cable assemblies installed on the interior of a one-family dwelling per 680.21(A)(4), wiring methods used for the supply circuit to a swimming pool pump motor must include an insulated, copper equipment grounding conductor not less than 12 AWG.

**(2) On or Within Buildings.** Where installed on or within buildings, electrical metallic tubing shall be permitted.

**(3) Flexible Connections.** Where necessary to employ flexible connections at or adjacent to the motor, liquidtight flexible metal or liquidtight flexible nonmetallic conduit with approved fittings shall be permitted.

**(4) One-Family Dwellings.** In the interior of dwelling units, or in the interior of accessory buildings associated with a dwelling unit, any of the wiring methods recognized in Chapter 3 of this Code that comply with the provisions of this section shall be permitted. Where run in a cable assembly, the equipment grounding conductor shall be permitted to be uninsulated, but it shall be enclosed within the outer sheath of the cable assembly.

**(5) Cord-and-Plug Connections.** Pool-associated motors shall be permitted to employ cord-and-plug connections. The flexible cord shall not exceed 900 mm (3 ft) in length. The flexible cord shall include a copper equipment grounding conductor sized in accordance with 250.122 but not smaller than 12 AWG. The cord shall terminate in a grounding-type attachment plug.

**(B) Double Insulated Pool Pumps.** A listed cord-and-plug-connected pool pump incorporating an approved system of double insulation that provides a means for grounding only the internal and nonaccessible, non-current-carrying metal parts of the pump shall be connected to any wiring method recognized in Chapter 3 that is suitable for the location. Where the bonding grid is connected to the equipment grounding conductor of the motor circuit in accordance with the second sentence of 680.26(B)(6)(a), the branch-circuit wiring shall comply with 680.21(A).

Cord-and-plug-connected double-insulated swimming pool filter pumps have been used with permanently installed aboveground pools and some storable pools, regardless of the pool's size, for many years without any known field-related problems. The internal metal parts of a swimming pool filter pump incorporating a system of double insulation are grounded; however, they are not required to be incorporated into the bonding system required by 680.26(B) because the act of bonding compromises the double-insulation system.

**(C) GFCI Protection.** Outlets supplying pool pump motors connected to single-phase, 120 volt through 240 volt branch circuits, rated 15 or 20 amperes, whether by receptacle or by direct connection, shall be provided with ground-fault circuit-interrupter protection for personnel.

Using the *Code* definition of the term *outlet* is important to correctly apply this requirement. The term *outlet* includes a point on the wiring system where a receptacle is installed to supply a cord-and plug-connected pool pump motor and also includes a point on the wiring system from where the branch circuit is run directly to the pool pump motor often referred to as a "hard-wired" installation.

## 680.22 Lighting, Receptacles, and Equipment

### (A) Receptacles.

**(1) Circulation and Sanitation System, Location.** Receptacles that provide power for water-pump motors or for other loads directly related to the circulation and sanitation system shall be located at least 3.0 m (10 ft) from the inside walls of the pool, or not less than 1.83 m (6 ft) from the inside walls of the pool if they meet all of the following conditions:

- (1) Consist of single receptacles
- (2) Employ a locking configuration
- (3) Are of the grounding type
- (4) Have GFCI protection

**(2) Other Receptacles, Location.** Other receptacles shall be not less than 1.83 m (6 ft) from the inside walls of a pool.

**(3) Dwelling Unit(s).** Where a permanently installed pool is installed at a dwelling unit(s), no fewer than one 125-volt, 15- or 20-ampere receptacle on a general-purpose branch circuit shall be located not less than 1.83 m (6 ft) from, and not more than 6.0 m (20 ft) from, the inside wall of the pool. This receptacle shall be located not more than 2.0 m (6 ft 6 in.) above the floor, platform, or grade level serving the pool.

**(4) GFCI Protection.** All 15- and 20-ampere, single-phase, 125-volt receptacles located within 6.0 m (20 ft) of the inside walls of a pool shall be protected by a ground-fault circuit interrupter.

**(5) Measurements.** In determining the dimensions in this section addressing receptacle spacings, the distance to be measured shall be the shortest path the supply cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, doorway with hinged or sliding door, window opening, or other effective permanent barrier.

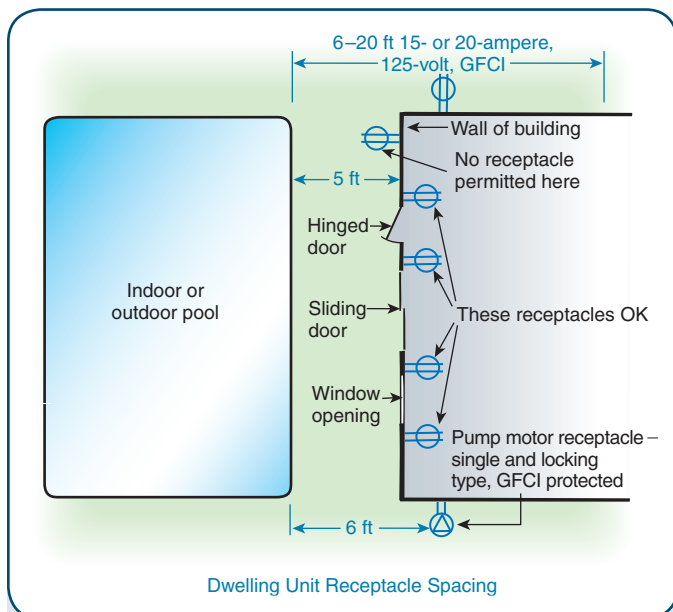

The requirements of 680.22(A) apply to receptacles located near a permanently installed pool or fountain. They do not apply to direct-connected equipment. Direct-connected pool pump motors are covered in 680.21(C). Permission is given in 680.22(A)(1) to allow a single locking- and grounding-type receptacle to supply a recirculation pump motor where the receptacle is located not less than 6 ft from the inside walls of the pool or fountain and is protected by a GFCI.

As required by 680.22(A)(3), each permanently installed pool in a residential setting is required to have at least one receptacle, which must be located at least 6 ft from the pool and not more than 20 ft from the pool. The intent of this requirement is to permit ordinary appliances to be safely plugged in and used near the pool but to avoid the need for extension cords in the vicinity of the pool. The 6-ft minimum dimension reduces the likelihood that an appliance with a 6-ft cord could be accidentally knocked into the pool.

GFCI protection of all 125-volt receptacles located within 20 ft of a pool or fountain is required by 680.22(A)(4). This rule applies to pools located outdoors or indoors, permanently installed or storable, and for residential or commercial use. Because people within 20 ft of a pool are normally subjected to dampness and moisture, the GFCI requirement within the 20-ft space is warranted.

Examples of receptacles meeting the requirements of 680.22(A) are shown in Exhibits 680.3 and 680.4. Receptacles within a structure are permitted to be less than 6 ft from the pool because the structure is considered to provide a permanent barrier separating the receptacle from the pool. Where this installation is at a dwelling unit, it is necessary to provide at least one receptacle between 6 ft and 20 ft from

**EXHIBIT 680.3** An example of a receptacle installed according to 680.22(A). For permanently installed pools at a dwelling unit(s), it is mandatory to install a 125-volt receptacle between 6 ft and 20 ft from the inside wall of the pool.

**EXHIBIT 680.4** Acceptable receptacle locations within 20 ft of a permanently installed swimming pool.

the inside walls of the pool. This location precludes having to run the cord of an appliance used on the pool deck through a doorway.

### (B) Luminaires, Lighting Outlets, and Ceiling-Suspended (Paddle) Fans.

(1) **New Outdoor Installation Clearances.** In outdoor pool areas, luminaires, lighting outlets, and ceiling-

suspended (paddle) fans installed above the pool or the area extending 1.5 m (5 ft) horizontally from the inside walls of the pool shall be installed at a height not less than 3.7 m (12 ft) above the maximum water level of the pool.

(2) **Indoor Clearances.** For installations in indoor pool areas, the clearances shall be the same as for outdoor areas unless modified as provided in this paragraph. If the branch circuit supplying the equipment is protected by a ground-fault circuit interrupter, the following equipment shall be permitted at a height not less than 2.3 m (7 ft 6 in.) above the maximum pool water level:

- (1) Totally enclosed luminaires
- (2) Ceiling-suspended (paddle) fans identified for use beneath ceiling structures such as provided on porches or patios

(3) **Existing Installations.** Existing luminaires and lighting outlets located less than 1.5 m (5 ft) measured horizontally from the inside walls of a pool shall be not less than 1.5 m (5 ft) above the surface of the maximum water level, shall be rigidly attached to the existing structure, and shall be protected by a ground-fault circuit interrupter.

(4) **GFCI Protection in Adjacent Areas.** Luminaires, lighting outlets, and ceiling-suspended (paddle) fans installed in the area extending between 1.5 m (5 ft) and 3.0 m (10 ft) horizontally from the inside walls of a pool shall be protected by a ground-fault circuit interrupter unless installed not less than 1.5 m (5 ft) above the maximum water level and rigidly attached to the structure adjacent to or enclosing the pool.

**(5) Cord-and-Plug-Connected Luminaires.** Cord-and-plug-connected luminaires shall comply with the requirements of 680.7 where installed within 4.9 m (16 ft) of any point on the water surface, measured radially.

Exhibit 680.5 provides diagrams that clarify the limitations of 680.22(B) for the areas surrounding outdoor and indoor pools.

**(C) Switching Devices.** Switching devices shall be located at least 1.5 m (5 ft) horizontally from the inside walls of a pool unless separated from the pool by a solid fence, wall, or other permanent barrier. Alternatively, a switch that is listed as being acceptable for use within 1.5 m (5 ft) shall be permitted.

**(D) Other Outlets.** Other outlets shall be not less than 3.0 m (10 ft) from the inside walls of the pool. Measurements shall be determined in accordance with 680.22(A)(5).

Informational Note: Other outlets may include, but are not limited to, remote-control, signaling, fire alarm, and communications circuits.

## 680.23 Underwater Luminaires

This section covers all luminaires installed below the normal water level of the pool.

### (A) General.

**(1) Luminaire Design, Normal Operation.** The design of an underwater luminaire supplied from a branch circuit either directly or by way of a transformer or power supply meeting the requirements of this section shall be such that, where the luminaire is properly installed without a ground-fault circuit interrupter, there is no shock hazard with any likely combination of fault conditions during normal use (not relamping).

Dry-niche, no-niche, or wet-niche underwater luminaires operating at more than 15 volts require GFCI protection. See the commentary following 680.5.

Branch-circuit conductors for dry-niche luminaires are required to be installed in approved rigid metal conduit, intermediate metal conduit, or rigid nonmetallic conduit from the luminaire to a panelboard or the service equipment.

**EXHIBIT 680.5** Limitations that apply to the placement of luminaires, lighting outlets, and ceiling-suspended fans in the area surrounding outdoor and indoor pools.

Branch-circuit conductors for wet-niche luminaires leaving the pool junction box are required to be enclosed in rigid metal conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit, or rigid nonmetallic conduit, except where located in or on buildings, where the conductors are permitted to be installed in electrical metallic tubing or electrical nonmetallic tubing. Unlike wet-niche luminaires, a junction box is not required for dry-niche luminaires. If a junction box is used, it is not required to be elevated or located as specified in 680.24(A)(2). (See Exhibits 680.1 and 680.6.)

**(2) Transformers and Power Supplies.** Transformers and power supplies used for the supply of underwater luminaires, together with the transformer or power supply enclosure, shall be listed for swimming pool and spa use. The transformer or power supply shall incorporate either a transformer of the isolated winding type, with an ungrounded secondary that has a grounded metal barrier between the primary and secondary windings, or one that incorporates an approved system of double insulation between the primary and secondary windings.

Unless marked otherwise, UL-listed swimming pool and spa transformers are not suitable for connection to a conduit that extends directly to an underwater pool light forming shell. Swimming pool and spa transformers are not permitted to be used outdoors unless marked “For Outdoor Use” or in an equivalent manner that signifies that they have been found acceptable for both outdoor and indoor use. See 110.3(B) for requirements on the installation and use of listed electrical equipment. Transformers and power supplies are required to be specifically listed for swimming pool use.

**(3) GFCI Protection, Relamping.** A ground-fault circuit interrupter shall be installed in the branch circuit supplying luminaires operating at more than the low voltage contact limit such that there is no shock hazard during relamping. The installation of the ground-fault circuit interrupter shall be such that there is no shock hazard with any likely fault-condition combination that involves a person in a conductive path from any ungrounded part of the branch circuit or the luminaire to ground.

**(4) Voltage Limitation.** No luminaires shall be installed for operation on supply circuits over 150 volts between conductors.

**(5) Location, Wall-Mounted Luminaires.** Luminaires mounted in walls shall be installed with the top of the luminaire lens not less than 450 mm (18 in.) below the normal

water level of the pool, unless the luminaire is listed and identified for use at lesser depths. No luminaire shall be installed less than 100 mm (4 in.) below the normal water level of the pool.

The reason for the 18-in. minimum submergence requirement for luminaires is to reduce the likelihood that a person in the water and hanging onto the side of the pool directly in front of a luminaire will have his or her chest in line with the luminaire. This section covers luminaires that have been investigated and found acceptable for use where a person’s chest may be directly in front of a luminaire. The highest level of leakage current in a pool coming from a wet-niche luminaire with a broken lens and bulb is found directly in front of the luminaire.

**(6) Bottom-Mounted Luminaires.** A luminaire facing upward shall comply with either (1) or (2):

- (1) Have the lens adequately guarded to prevent contact by any person
- (2) Be listed for use without a guard

**(7) Dependence on Submersion.** Luminaires that depend on submersion for safe operation shall be inherently protected against the hazards of overheating when not submerged.

Luminaires that depend on submersion for safe operation are required to be inherently protected against the hazards of overheating when not submerged; for example, during a relamping process. Protection against overheating is required to be built into a luminaire or to be a part of it. A remotely located low-water cutoff switch does not provide the intended protection.

**(8) Compliance.** Compliance with these requirements shall be obtained by the use of a listed underwater luminaire and by installation of a listed ground-fault circuit interrupter in the branch circuit or a listed transformer or power supply for luminaires operating at not more than the low voltage contact limit.

**(B) Wet-Niche Luminaires.**

**(1) Forming Shells.** Forming shells shall be installed for the mounting of all wet-niche underwater luminaires and shall be equipped with provisions for conduit entries. Metal parts of the luminaire and forming shell in contact with the pool water shall be of brass or other approved corrosion-resistant metal. All forming shells used with nonmetallic conduit systems, other than those that are part of a listed low-voltage lighting system not requiring grounding, shall

include provisions for terminating an 8 AWG copper conductor.

**(2) Wiring Extending Directly to the Forming Shell.** Conduit shall be installed from the forming shell to a junction box or other enclosure conforming to the requirements in 680.24. Conduit shall be rigid metal, intermediate metal, liquidtight flexible nonmetallic, or rigid nonmetallic.

(a) *Metal Conduit.* Metal conduit shall be approved and shall be of brass or other approved corrosion-resistant metal.

(b) *Nonmetallic Conduit.* Where a nonmetallic conduit is used, an 8 AWG insulated solid or stranded copper bonding jumper shall be installed in this conduit unless a listed low-voltage lighting system not requiring grounding is used. The bonding jumper shall be terminated in the forming shell, junction box or transformer enclosure, or ground-fault circuit-interrupter enclosure. The termination of the 8 AWG bonding jumper in the forming shell shall be covered with, or encapsulated in, a listed potting compound to protect the connection from the possible deteriorating effect of pool water.

Where rigid nonmetallic conduit or liquidtight flexible nonmetallic conduit is used between a forming shell for a wet-niche luminaire and a junction box or other enclosure, an 8 AWG insulated copper bonding jumper is required to be installed in the conduit to provide electrical continuity between the forming shell and the junction box or other enclosure. The conduit must be sized large enough to enclose both the 8 AWG insulated copper bonding jumper and the approved flexible cord that supplies the wet-niche luminaire, to facilitate easy withdrawal and insertion of the bonding conductor and the cord. Low-voltage lighting systems that are listed for installation without an equipment grounding or bonding conductor are exempt from this requirement.

**(3) Equipment Grounding Provisions for Cords.** Other than listed low-voltage lighting systems not requiring grounding wet-niche luminaires that are supplied by a flexible cord or cable shall have all exposed non-current-carrying metal parts grounded by an insulated copper equipment grounding conductor that is an integral part of the cord or cable. This grounding conductor shall be connected to a grounding terminal in the supply junction box, transformer enclosure, or other enclosure. The grounding conductor shall not be smaller than the supply conductors and not smaller than 16 AWG.

**(4) Luminaire Grounding Terminations.** The end of the flexible-cord jacket and the flexible-cord conductor termina-

tions within a luminaire shall be covered with, or encapsulated in, a suitable potting compound to prevent the entry of water into the luminaire through the cord or its conductors. If present, the grounding connection within a luminaire shall be similarly treated to protect such connection from the deteriorating effect of pool water in the event of water entry into the luminaire.

**(5) Luminaire Bonding.** The luminaire shall be bonded to, and secured to, the forming shell by a positive locking device that ensures a low-resistance contact and requires a tool to remove the luminaire from the forming shell. Bonding shall not be required for luminaires that are listed for the application and have no non-current-carrying metal parts.

**(6) Servicing.** All wet-niche luminaires shall be removable from the water for inspection, relamping, or other maintenance. The forming shell location and length of cord in the forming shell shall permit personnel to place the removed luminaire on the deck or other dry location for such maintenance. The luminaire maintenance location shall be accessible without entering or going in the pool water.

Custom swimming pool installations where the pool is incorporated as an architectural feature of a building or structure can present access problems for those who have to change the lamps of an underwater luminaire. In some cases, the length of the flexible cord connected to a wet-niche luminaire does not permit the luminaire to be removed from the pool for relamping or servicing. To address the concern over a person having to be in the pool in order to change lamps, this requirement specifies that the underwater luminaire installation has to be made such that changing of the lamp occurs on the pool deck or other dry location outside of the pool, and the location can be accessed without having to enter the pool water.

### (C) Dry-Niche Luminaires.

**(1) Construction.** A dry-niche luminaire shall have provision for drainage of water. Other than listed low voltage luminaires not requiring grounding, a dry-niche luminaire shall have means for accommodating one equipment grounding conductor for each conduit entry.

**(2) Junction Box.** A junction box shall not be required but, if used, shall not be required to be elevated or located as specified in 680.24(A)(2) if the luminaire is specifically identified for the purpose.

**(D) No-Niche Luminaires.** A no-niche luminaire shall meet the construction requirements of 680.23(B)(3) and be installed in accordance with the requirements of 680.23(B).

Where connection to a forming shell is specified, the connection shall be to the mounting bracket.

**(E) Through-Wall Lighting Assembly.** A through-wall lighting assembly shall be equipped with a threaded entry or hub, or a nonmetallic hub, for the purpose of accommodating the termination of the supply conduit. A through-wall lighting assembly shall meet the construction requirements of 680.23(B)(3) and be installed in accordance with the requirements of 680.23. Where connection to a forming shell is specified, the connection shall be to the conduit termination point.

**(F) Branch-Circuit Wiring.**

The requirements in 680.24(A) through (F) cover the construction and installation of boxes and enclosures associated with underwater luminaires. Boxes and enclosures used for the supply wiring to wet-niche and no-niche underwater luminaires must be listed for the purpose by a recognized testing laboratory. The requirements of 680.24(D) ensure the availability of integral grounding terminals necessary for the grounding and bonding of underwater luminaires. A box that is listed but not specifically for use with swimming pools does not provide the correct number of integral grounding and bonding terminals. The number of grounding terminals in a box or enclosure is required to be one more than the number of conduit entries for which the box is designed.

In an installation where nonmetallic conduit is the wiring method between the wet-niche forming shell and the deck (junction) box, a bonding jumper and an equipment grounding conductor in that conduit must be terminated in the junction box. The bonding jumper is covered in 680.23(B)(2)(b). The use of nonmetallic conduit requires the installation of an insulated, copper bonding jumper in that section of conduit between the deck box and the wet-niche forming shell. This conductor can be solid or stranded and must not be smaller than 8 AWG. The function of this conductor is twofold. It permanently bonds all non-current-carrying metal surfaces of the forming shell to any non-current-carrying parts of the deck box and to the equipment grounding conductor of the circuit that supplies the wet-niche luminaire. Additionally, this conductor serves as the path for ground-fault current in the event of a ground fault when the wet-niche luminaire is removed from the forming shell, as is typically done during relamping. Damage to the wet-niche luminaire supply cord could result in this ground-fault scenario.

The equipment grounding conductor is the one contained in the flexible cord supplying the wet-niche luminaire. In accordance with 680.23(B)(3), this conductor is

required to be insulated, copper, and sized no smaller than the circuit conductors within the cord, but not smaller than 16 AWG.

In addition to the bonding jumper and equipment grounding conductor of the cord contained in the section of nonmetallic conduit between the forming shell and the deck box, the wiring method from the deck box to the power source is also required to contain a separate equipment grounding conductor. This equipment grounding conductor is required by 680.23(F)(2) and must be insulated, copper, and not smaller than 12 AWG. The grounding terminals within the deck (junction) box are used to terminate and bond together all of the conductors.

Exhibit 680.6 illustrates an installation of a forming shell for a wet-niche luminaire and a flush junction (deck) box. (See Exhibit 680.1 for surface deck boxes.)

**EXHIBIT 680.6** A flush junction (deck) box and a forming shell for a wet-niche luminaire installed according to 680.24(A)(2).

**(1) Wiring Methods.** Branch-circuit wiring on the supply side of enclosures and junction boxes connected to conduits run to wet-niche and no-niche luminaires, and the field wiring compartments of dry-niche luminaires, shall be installed using rigid metal conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit, rigid polyvinyl chloride conduit, or reinforced thermosetting resin conduit. Where installed on buildings, electrical metallic tubing shall be permitted, and where installed within buildings, electrical nonmetallic tubing, Type MC cable, electrical metallic tubing, or Type AC cable shall be permitted. In all cases, an insulated equipment grounding conductor sized in accordance

with Table 250.122 but not less than 12 AWG shall be required.

*Exception: Where connecting to transformers for pool lights, liquidtight flexible metal conduit shall be permitted. The length shall not exceed 1.8 m (6 ft) for any one length or exceed 3.0 m (10 ft) in total length used.*

**(2) Equipment Grounding.** Other than listed low-voltage luminaires not requiring grounding, all through-wall lighting assemblies, wet-niche, dry-niche, or no-niche luminaires shall be connected to an insulated copper equipment grounding conductor installed with the circuit conductors. The equipment grounding conductor shall be installed without joint or splice except as permitted in (F)(2)(a) and (F)(2)(b). The equipment grounding conductor shall be sized in accordance with Table 250.122 but shall not be smaller than 12 AWG.

*Exception: An equipment grounding conductor between the wiring chamber of the secondary winding of a transformer and a junction box shall be sized in accordance with the overcurrent device in this circuit.*

(a) If more than one underwater luminaire is supplied by the same branch circuit, the equipment grounding conductor, installed between the junction boxes, transformer enclosures, or other enclosures in the supply circuit to wet-niche luminaires, or between the field-wiring compartments of dry-niche luminaires, shall be permitted to be terminated on grounding terminals.

(b) If the underwater luminaire is supplied from a transformer, ground-fault circuit interrupter, clock-operated switch, or a manual snap switch that is located between the panelboard and a junction box connected to the conduit that extends directly to the underwater luminaire, the equipment grounding conductor shall be permitted to terminate on grounding terminals on the transformer, ground-fault circuit interrupter, clock-operated switch enclosure, or an outlet box used to enclose a snap switch.

**(3) Conductors.** Conductors on the load side of a ground-fault circuit interrupter or of a transformer, used to comply with the provisions of 680.23(A)(8), shall not occupy raceways, boxes, or enclosures containing other conductors unless one of the following conditions applies:

- (1) The other conductors are protected by ground-fault circuit interrupters.
- (2) The other conductors are grounding conductors.
- (3) The other conductors are supply conductors to a feed-through-type ground-fault circuit interrupter.
- (4) Ground-fault circuit interrupters shall be permitted in a panelboard that contains circuits protected by other than ground-fault circuit interrupters.

## 680.24 Junction Boxes and Electrical Enclosures for Transformers or Ground-Fault Circuit Interrupters

**(A) Junction Boxes.** A junction box connected to a conduit that extends directly to a forming shell or mounting bracket of a no-niche luminaire shall meet the requirements of this section.

**(1) Construction.** The junction box shall be listed as a swimming pool junction box and shall comply with the following conditions:

- (1) Be equipped with threaded entries or hubs or a nonmetallic hub
- (2) Be comprised of copper, brass, suitable plastic, or other approved corrosion-resistant material
- (3) Be provided with electrical continuity between every connected metal conduit and the grounding terminals by means of copper, brass, or other approved corrosion-resistant metal that is integral with the box

**(2) Installation.** Where the luminaire operates over the low voltage contact limit, the junction box location shall comply with (A)(2)(a) and (A)(2)(b). Where the luminaire operates at the low voltage contact limit or less, the junction box location shall be permitted to comply with (A)(2)(c).

(a) *Vertical Spacing.* The junction box shall be located not less than 100 mm (4 in.), measured from the inside of the bottom of the box, above the ground level, or pool deck, or not less than 200 mm (8 in.) above the maximum pool water level, whichever provides the greater elevation.

(b) *Horizontal Spacing.* The junction box shall be located not less than 1.2 m (4 ft) from the inside wall of the pool, unless separated from the pool by a solid fence, wall, or other permanent barrier.

(c) *Flush Deck Box.* If used on a lighting system operating at the low voltage contact limit or less, a flush deck box shall be permitted if both of the following conditions are met:

- (1) An approved potting compound is used to fill the box to prevent the entrance of moisture.
- (2) The flush deck box is located not less than 1.2 m (4 ft) from the inside wall of the pool.

**(B) Other Enclosures.** An enclosure for a transformer, ground-fault circuit interrupter, or a similar device connected to a conduit that extends directly to a forming shell or mounting bracket of a no-niche luminaire shall meet the requirements of this section.

**(1) Construction.** The enclosure shall be listed and labeled for the purpose and meet the following requirements:

- (1) Equipped with threaded entries or hubs or a nonmetallic hub
- (2) Comprised of copper, brass, suitable plastic, or other approved corrosion-resistant material
- (3) Provided with an approved seal, such as duct seal at the conduit connection, that prevents circulation of air between the conduit and the enclosures
- (4) Provided with electrical continuity between every connected metal conduit and the grounding terminals by means of copper, brass, or other approved corrosion-resistant metal that is integral with the box

## (2) Installation.

(a) *Vertical Spacing.* The enclosure shall be located not less than 100 mm (4 in.), measured from the inside of the bottom of the box, above the ground level, or pool deck, or not less than 200 mm (8 in.) above the maximum pool water level, whichever provides the greater elevation.

(b) *Horizontal Spacing.* The enclosure shall be located not less than 1.2 m (4 ft) from the inside wall of the pool, unless separated from the pool by a solid fence, wall, or other permanent barrier.

**(C) Protection.** Junction boxes and enclosures mounted above the grade of the finished walkway around the pool shall not be located in the walkway unless afforded additional protection, such as by location under diving boards, adjacent to fixed structures, and the like.

**(D) Grounding Terminals.** Junction boxes, transformer and power-supply enclosures, and ground-fault circuit-interrupter enclosures connected to a conduit that extends directly to a forming shell or mounting bracket of a no-niche luminaire shall be provided with a number of grounding terminals that shall be no fewer than one more than the number of conduit entries.

**(E) Strain Relief.** The termination of a flexible cord of an underwater luminaire within a junction box, transformer or power-supply enclosure, ground-fault circuit interrupter, or other enclosure shall be provided with a strain relief.

**(F) Grounding.** The equipment grounding conductor terminals of a junction box, transformer enclosure, or other enclosure in the supply circuit to a wet-niche or no-niche luminaire and the field-wiring chamber of a dry-niche luminaire shall be connected to the equipment grounding terminal of the panelboard. This terminal shall be directly connected to the panelboard enclosure.

## 680.25 Feeders

These provisions shall apply to any feeder on the supply side of panelboards supplying branch circuits for pool equipment

covered in Part II of this article and on the load side of the service equipment or the source of a separately derived system.

## (A) Wiring Methods.

**(1) Feeders.** Feeders shall be installed in rigid metal conduit or intermediate metal conduit. The following wiring methods shall be permitted if not subject to physical damage:

- (1) Liquidtight flexible nonmetallic conduit
- (2) Rigid polyvinyl chloride conduit
- (3) Reinforced thermosetting resin conduit
- (4) Electrical metallic tubing where installed on or within a building
- (5) Electrical nonmetallic tubing where installed within a building
- (6) Type MC cable where installed within a building and if not subject to corrosive environment

*Exception:* An existing feeder between an existing remote panelboard and service equipment shall be permitted to run in flexible metal conduit or an approved cable assembly that includes an equipment grounding conductor within its outer sheath. The equipment grounding conductor shall comply with 250.24(A)(5).

**(2) Aluminum Conduit.** Aluminum conduit shall not be permitted in the pool area where subject to corrosion.

**(B) Grounding.** An equipment grounding conductor shall be installed with the feeder conductors between the grounding terminal of the pool equipment panelboard and the grounding terminal of the applicable service equipment or source of a separately derived system. For other than (1) existing feeders covered in 680.25(A), exception, or (2) feeders to separate buildings that do not utilize an insulated equipment grounding conductor in accordance with 680.25(B)(2), this equipment grounding conductor shall be insulated.

**(1) Size.** This conductor shall be sized in accordance with 250.122 but not smaller than 12 AWG. On separately derived systems, this conductor shall be sized in accordance with 250.30(A)(8) but not smaller than 8 AWG.

**(2) Separate Buildings.** A feeder to a separate building or structure shall be permitted to supply swimming pool equipment branch circuits, or feeders supplying swimming pool equipment branch circuits, if the grounding arrangements in the separate building meet the requirements in 250.32(B). Where installed in other than existing feeders covered in 680.25(A), Exception, a separate equip-

ment grounding conductor shall be an insulated conductor.

The insulated equipment grounding conductor can be aluminum or copper and is required to be installed in a raceway. It should be understood that for an existing remote panelboard, the exception to 680.25(A) permits an approved cable assembly with an insulated or covered aluminum or copper equipment grounding conductor.

Swimming pool equipment supplied by a separately derived system is covered in 680.25(B). Where a remote panelboard supplying a pool is supplied by a separately derived system, the rules covering the grounding conductor apply only to the feeder between the separately derived system and the panelboard, not all the way back to the service, which might be high voltage.

The general rule in 680.25(B) requires an equipment grounding conductor to be installed between a panelboard serving swimming pool equipment and the service or the source of a separately derived system. Section 680.25(B)(2) allows pool equipment to be supplied from a remote panelboard in a separate building where an insulated equipment grounding conductor is installed with the feeder circuit conductors run from the service (or derived system) to the panelboard and where the installation complies with 250.32(B). See Exhibit 680.7 for an illustration of applying the wiring method and grounding requirements to a feeder-supplied panelboard that provides branch circuits for swimming pool-related equipment. Also note the branch-circuit wiring methods shown in this illustration.

## 680.26 Equipotential Bonding

**(A) Performance.** The equipotential bonding required by this section shall be installed to reduce voltage gradients in the pool area.

It is important to understand the difference between the terms *bonding* and *grounding* as they apply to Article 680. As defined in Article 100, bonding is “connected to establish electrical continuity and conductivity.” As described in 680.26(A), the function of equipotential bonding differs from the primary function of bonding to meet the requirements of Article 250 in that providing a path for ground-fault current is not the function of the equipotential bonding grid and associated bonding conductors.

Creating an electrically safe environment in and around permanently installed swimming pools requires the installation of a bonding system with the sole function of establishing equal electrical potential (voltage) in the vicinity of the swimming pool. A person who is immersed in a pool or who is dripping wet has a large amount of exposed skin, and if lying or walking on a concrete deck or other conductive perimeter surface, is extremely vulnerable to any differences in electrical potential that may be present in the pool area.

The primary purpose of bonding in and around swimming pools is to ensure that voltage gradients in the pool area are not present. Section 680.26(B) specifies that the 8 AWG conductor’s only function is equipotential bonding to eliminate the voltage gradient in the pool area and the bonding conductor is not required to extend or connect to any parts or equipment other than those covered in 680.26(B)(1)

**EXHIBIT 680.7** Wiring method and grounding requirements per 680.25(A) and (B) for a feeder panelboard supplying swimming pool equipment.

through (B)(7) and to a pool water bonding element covered in 680.26(C).

The reason for electrically connecting all of the metal parts described in 680.26(B)(1) through (7) is to ensure that they all are at the same electrical potential. This bonding reduces possible injurious or disabling shock hazards created by stray currents in the ground or piping connected to the swimming pool. Stray currents can also exist in nonmetallic piping because of the low resistivity of chlorinated water. See Exhibit 680.8.

**EXHIBIT 680.8** Bonding of conductive metal equipment and parts associated with a swimming pool.

**(B) Bonded Parts.** The parts specified in 680.26(B)(1) through (B)(7) shall be bonded together using solid copper conductors, insulated covered, or bare, not smaller than 8 AWG or with rigid metal conduit of brass or other identified corrosion-resistant metal. Connections to bonded parts shall be made in accordance with 250.8. An 8 AWG or larger solid copper bonding conductor provided to reduce voltage gradients in the pool area shall not be required to be extended or attached to remote panelboards, service equipment, or electrodes.

**(1) Conductive Pool Shells.** Bonding to conductive pool shells shall be provided as specified in 680.26(B)(1)(a) or (B)(1)(b). Poured concrete, pneumatically applied or sprayed concrete, and concrete block with painted or plastered coatings shall all be considered conductive materials due to water permeability and porosity. Vinyl liners and fiberglass composite shells shall be considered to be nonconductive materials.

Conductive pool shells include those constructed of poured concrete, pneumatically applied concrete, concrete block, and, of course, metal. Fiberglass and vinyl-lined pools are not considered to be conductive pool shells and are not subject to having a bonding grid installed around the entire contour of the pool shell.

Encapsulated reinforcing steel is not likely to provide the conductivity necessary to establish the required common bonding grid around the contour of a conductive pool shell. A bonding grid around the contour of the pool shell will not be formed if the steel is effectively encapsulated by a listed compound during installation and manufacturing. Therefore, a bonding connection to the encapsulated reinforcing steel, such as the epoxy-coated rebar in Exhibit 680.9, is not required. However, a copper bonding grid around the contour of a conductive pool shell must be provided and constructed as prescribed in 680.26(B)(1)(b).

**EXHIBIT 680.9** Epoxy-coated rebar, which does not require bonding.

In Exhibit 680.10, structural reinforcing steel serves as a common point to which all metal appurtenances associated with the pool are connected. This method of connection is one way of satisfying the requirement to bond all metal parts together. Individual pieces of hardware such as the hooks used to attach safety or lane ropes, that are less than 4 in. in any dimension and do not penetrate into the pool structure more than 1 in. are not required to be bonded, per 680.26(B)(5). The flush deck box meets the provisions of 680.24(A).

(a) *Structural Reinforcing Steel.* Unencapsulated structural reinforcing steel shall be bonded together by steel tie wires or the equivalent. Where structural reinforcing steel is

**EXHIBIT 680.10** A poured-concrete pool with structural reinforcing steel that serves as the pool shell bonding grid.

encapsulated in a nonconductive compound, a copper conductor grid shall be installed in accordance with 680.26(B)(1)(b).

(b) *Copper Conductor Grid.* A copper conductor grid shall be provided and shall comply with (b)(1) through (b)(4).

- (1) Be constructed of minimum 8 AWG bare solid copper conductors bonded to each other at all points of crossing. The bonding shall be in accordance with 250.8 or other approved means.
- (2) Conform to the contour of the pool
- (3) Be arranged in a 300-mm (12-in.) by 300-mm (12-in.) network of conductors in a uniformly spaced perpendicular grid pattern with a tolerance of 100 mm (4 in.)
- (4) Be secured within or under the pool no more than 150 mm (6 in.) from the outer contour of the pool shell

**(2) Perimeter Surfaces.** The perimeter surface shall extend for 1 m (3 ft) horizontally beyond the inside walls of the pool and shall include unpaved surfaces, as well as poured concrete surfaces and other types of paving. Perimeter surfaces less than 1 m (3 ft) separated by a permanent wall or building 1.5 m (5 ft) in height or more shall require equipotential bonding on the pool side of the permanent wall or building. Bonding to perimeter surfaces shall be provided as specified in 680.26(B)(2)(a) or (2)(b) and shall be attached to the pool reinforcing steel or copper conductor grid at a minimum of four (4) points uniformly spaced around the

perimeter of the pool. For nonconductive pool shells, bonding at four points shall not be required.

The requirement for bonding perimeter surfaces applies to paved and unpaved surfaces. An example of an unpaved perimeter surface would be the lawn surrounding a permanently installed aboveground swimming pool. Where the paved portion of the perimeter surface extends less than 3 ft horizontally from the inside walls of the pool, the perimeter bonding grid must be continued under the adjacent unpaved perimeter surface. If physical constraints (such as a wall or other physical barrier) prevent the perimeter from extending 3 ft beyond the inside walls of the pool, the bonding grid is required only to extend under the available perimeter area.

The perimeter bonding grid can be comprised of structural reinforcing metal (rebar or welded wire mesh) that is conductive to the perimeter surface and installed in or under the perimeter surface. Where structural reinforcing steel is not available, a single, bare, solid 8 AWG or larger copper conductor can be installed around the perimeter of the pool in an area measuring between 18 in. and 24 in. from the inside pool walls. This 8 AWG bonding conductor can be installed in the paving material (i.e., in the concrete), or it can be buried in the material (*subgrade*) below the paving material. Where buried, the bonding conductor is to be not less than 4 in. and not more than 6 in. below the surface level of the subgrade material.

The perimeter surface bonding medium has to be connected, at four evenly spaced points around the pool perimeter, to either the structural steel of a conductive pool shell or to the copper bonding grid provided for the conductive pool shell that has encapsulated rebar or no rebar at all. Connection between the perimeter bonding medium and non-conductive pool shells is not required.

(a) **Structural Reinforcing Steel.** Structural reinforcing steel shall be bonded in accordance with 680.26(B)(1)(a).

(b) **Alternate Means.** Where structural reinforcing steel is not available or is encapsulated in a nonconductive compound, a copper conductor(s) shall be utilized where the following requirements are met:

- (1) At least one minimum 8 AWG bare solid copper conductor shall be provided.
- (2) The conductors shall follow the contour of the perimeter surface.
- (3) Only listed splices shall be permitted.
- (4) The required conductor shall be 450 mm to 600 mm (18 in. to 24 in.) from the inside walls of the pool.
- (5) The required conductor shall be secured within or under the perimeter surface 100 mm to 150 mm (4 in. to 6 in.) below the subgrade.

(3) **Metallic Components.** All metallic parts of the pool structure, including reinforcing metal not addressed in 680.26(B)(1)(a), shall be bonded. Where reinforcing steel is encapsulated with a nonconductive compound, the reinforcing steel shall not be required to be bonded.

(4) **Underwater Lighting.** All metal forming shells and mounting brackets of no-niche luminaires shall be bonded.

*Exception: Listed low-voltage lighting systems with nonmetallic forming shells shall not require bonding.*

(5) **Metal Fittings.** All metal fittings within or attached to the pool structure shall be bonded. Isolated parts that are not over 100 mm (4 in.) in any dimension and do not penetrate into the pool structure more than 25 mm (1 in.) shall not require bonding.

(6) **Electrical Equipment.** Metal parts of electrical equipment associated with the pool water circulating system, including pump motors and metal parts of equipment associated with pool covers, including electric motors, shall be bonded.

*Exception: Metal parts of listed equipment incorporating an approved system of double insulation shall not be bonded.*

(a) **Double-Insulated Water Pump Motors.** Where a double-insulated water pump motor is installed under the provisions of this rule, a solid 8 AWG copper conductor of sufficient length to make a bonding connection to a replacement motor shall be extended from the bonding grid to an accessible point in the vicinity of the pool pump motor. Where there is no connection between the swimming pool bonding grid and the equipment grounding system for the premises, this bonding conductor shall be connected to the equipment grounding conductor of the motor circuit.

(b) **Pool Water Heaters.** For pool water heaters rated at more than 50 amperes and having specific instructions regarding bonding and grounding, only those parts designated to be bonded shall be bonded and only those parts designated to be grounded shall be grounded.

(7) **Fixed Metal Parts.** All fixed metal parts shall be bonded including, but not limited to, metal-sheathed cables and raceways, metal piping, metal awnings, metal fences, and metal door and window frames.

The metal parts required to be bonded per 680.26(B) include all metal parts of electrical equipment associated with the water-circulating system of the pool, all metal parts of the pool structure, and all fixed metal parts, which include conduit and piping, metal door frames, and metal window frames, within 5 ft of the inside walls of the pool and not separated by a permanent barrier. Other examples of fixed metal parts covered by this requirement include metal fences and metal awnings. The bonding of these parts can be accomplished by one or more of the following methods using a solid 8 AWG or larger, insulated, covered, or bare copper conductor:

- Connecting the parts directly to each other in series or parallel configurations
- Connecting the parts to the unencapsulated structural metal forming the shell of a conductive pool or connecting the parts to a copper conductor grid system used around the contour of a conductive pool shell
- Connecting the parts together using the pool shell constructed of bolted or welded steel as a common connection point.
- Connecting the parts to the perimeter bonding grid consisting of either structural reinforcing steel (rebar or welded wire mesh) or a solid 8 AWG bare copper conductor encircling the perimeter of the pool

Brass or other corrosion-resistant rigid metal conduit (RMC) can also be used as a bonding conductor for connecting metal parts together. See Exhibit 680.8 for an example of using brass RMC as the method of bonding two

electrical enclosures and as a point to connect bonding jumpers run to the pool reinforcing steel and stainless steel ladder.

As specified in 250.8, exothermic welding, pressure connectors and clamps specifically listed for the purpose, and other listed means are permitted as the method of connecting bonding conductors to swimming pool equipment required to be bonded. Connections in pool areas must be suitable for wet conditions and high levels of chlorine. High concentrations of chlorine in swimming pool water make the wet locations in the vicinity of swimming pool areas (including many pool pump rooms) a corrosive environment. The integrity of the bonding connections should be periodically inspected, particularly those bonding connections between the 8 AWG copper conductor and, for instance, an aluminum (or other dissimilar metal) ladder. See Exhibit 680.11 for an illustration of two acceptable methods of making swimming pool bonding connections.

**EXHIBIT 680.11** Use of listed connectors for making bonding connections at a swimming pool.

*Exception No. 1: Those separated from the pool by a permanent barrier that prevents contact by a person shall not be required to be bonded.*

*Exception No. 2: Those greater than 1.5 m (5 ft) horizontally of the inside walls of the pool shall not be required to be bonded.*

*Exception No. 3: Those greater than 3.7 m (12 ft) measured vertically above the maximum water level of the pool, or as measured vertically above any observation stands, towers, or platforms, or any diving structures, shall not be required to be bonded.*

**(C) Pool Water.** An intentional bond of a minimum conductive surface area of 5800 mm<sup>2</sup> (9 in.<sup>2</sup>) shall be installed in contact with the pool water. This bond shall be permitted to consist of parts that are required to be bonded in 680.26(B).

This requirement ensures that a conductive element that is part of the pool bonding system is in direct contact with the pool water. Where bonded items such as underwater luminaires, rails, or ladders are in direct contact with the pool water and provide the required surface area, it is not necessary to provide another conductive element. However, where the pool does not include any of these items, it is necessary for one to be installed. There are devices that have been specifically listed as a means to provide this contact with the pool water. The requirement applies to all permanently installed swimming pools covered by the requirements in Part II of Article 680.

## 680.27 Specialized Pool Equipment

**(A) Underwater Audio Equipment.** All underwater audio equipment shall be identified for the purpose.

**(1) Speakers.** Each speaker shall be mounted in an approved metal forming shell, the front of which is enclosed by a captive metal screen, or equivalent, that is bonded to, and secured to, the forming shell by a positive locking device that ensures a low-resistance contact and requires a tool to open for installation or servicing of the speaker. The forming shell shall be installed in a recess in the wall or floor of the pool.

**(2) Wiring Methods.** Rigid metal conduit of brass or other identified corrosion-resistant metal, liquidtight flexible non-metallic conduit (LFNC-B), rigid polyvinyl chloride conduit, or reinforced thermosetting resin conduit shall extend from the forming shell to a listed junction box or other enclosure as provided in 680.24. Where rigid polyvinyl chloride conduit, reinforced thermosetting resin conduit, or liquidtight flexible nonmetallic conduit is used, an 8 AWG insulated solid or stranded copper bonding jumper shall be installed in this conduit. The bonding jumper shall be terminated in the forming shell and the junction box. The termination of the 8 AWG bonding jumper in the forming shell shall be covered with, or encapsulated in, a listed potting compound to protect such connection from the possible deteriorating effect of pool water.

**(3) Forming Shell and Metal Screen.** The forming shell and metal screen shall be of brass or other approved corrosion-resistant metal. All forming shells shall include provisions for terminating an 8 AWG copper conductor.

**(B) Electrically Operated Pool Covers.**

**(1) Motors and Controllers.** The electric motors, controllers, and wiring shall be located not less than 1.5 m (5 ft) from the inside wall of the pool unless separated from the pool by a wall, cover, or other permanent barrier. Electric motors installed below grade level shall be of the totally enclosed type. The device that controls the operation of the motor for an electrically operated pool cover shall be located such that the operator has full view of the pool.

Informational Note No. 1: For cabinets installed in damp and wet locations, see 312.2.

Informational Note No. 2: For switches or circuit breakers installed in wet locations, see 404.4.

Informational Note No. 3: For protection against liquids, see 430.11.

**(2) Protection.** The electric motor and controller shall be connected to a circuit protected by a ground-fault circuit interrupter.

**(C) Deck Area Heating.** The provisions of this section shall apply to all pool deck areas, including a covered pool, where electrically operated comfort heating units are installed within 6.0 m (20 ft) of the inside wall of the pool.

**(1) Unit Heaters.** Unit heaters shall be rigidly mounted to the structure and shall be of the totally enclosed or guarded type. Unit heaters shall not be mounted over the pool or within the area extending 1.5 m (5 ft) horizontally from the inside walls of a pool.

**(2) Permanently Wired Radiant Heaters.** Radiant electric heaters shall be suitably guarded and securely fastened to their mounting device(s). Heaters shall not be installed over a pool or within the area extending 1.5 m (5 ft) horizontally from the inside walls of the pool and shall be mounted at least 3.7 m (12 ft) vertically above the pool deck unless otherwise approved.

**(3) Radiant Heating Cables Not Permitted.** Radiant heating cables embedded in or below the deck shall not be permitted.

Only unit heaters and permanently connected radiant heaters are permitted in the area that extends 5 ft to 20 ft horizontally from the inside walls of a pool. Electric radiant heating cables embedded in the deck are not permitted.

### III. Storable Pools

#### 680.30 General

Electrical installations at storable pools shall comply with the provisions of Part I and Part III of this article.

Storable pools can be readily disassembled and are limited (other than inflatable type) to a maximum water depth of 42 in. Pools of any dimension with inflatable walls are considered storable. See the definition of *storable swimming, wading, or immersion pool* in 680.2. This type of pool and its associated equipment do not require bonding conductors. However, the filter pump must be double insulated, and the provision of grounding means consisting of an equipment grounding conductor that is an integral part of the flexible cord also is required. The 3-ft length limitation for flexible cords in 680.7 does not apply to the power cord of equipment listed for use with a storable swimming pool. Underwriters Laboratories lists portable filter pumps for use with storable pools having longer cords. All electrical equipment used with a storable pool is required to have GFCI protection for personnel. Exhibit 680.12 illustrates an inflatable swimming pool that is considered to be a storable swimming pool regardless of the water depth.

#### 680.31 Pumps

A cord-connected pool filter pump shall incorporate an approved system of double insulation or its equivalent and shall be provided with means for grounding only the internal and nonaccessible non-current-carrying metal parts of the appliance.

The means for grounding shall be an equipment grounding conductor run with the power-supply conductors in the flexible cord that is properly terminated in a grounding-type attachment plug having a fixed grounding contact member.

Cord-connected pool filter pumps shall be provided with a ground-fault circuit interrupter that is an integral part of the attachment plug or located in the power supply cord within 300 mm (12 in.) of the attachment plug.

#### 680.32 Ground-Fault Circuit Interrupters Required

All electrical equipment, including power-supply cords, used with storable pools shall be protected by ground-fault circuit interrupters.

All 125-volt, 15- and 20-ampere receptacles located within 6.0 m (20 ft) of the inside walls of a storable pool shall be protected by a ground-fault circuit interrupter. In determining these dimensions, the distance to be measured shall be the shortest path the supply cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, doorway with hinged or sliding door, window opening, or other effective permanent barrier.

Informational Note: For flexible cord usage, see 400.4.

**EXHIBIT 680.12** Example of an inflatable swimming pool subject to the requirements in Parts I and III of Article 680.

### 680.33 Luminaires

An underwater luminaire, if installed, shall be installed in or on the wall of the storable pool. It shall comply with either 680.33(A) or (B).

**(A) Within the Low Voltage Contact Limit.** A luminaire shall be part of a cord-and-plug-connected lighting assembly. This assembly shall be listed as an assembly for the purpose and have the following construction features:

- (1) No exposed metal parts
- (2) A luminaire lamp that is suitable for use at the supplied voltage
- (3) An impact-resistant polymeric lens, luminaire body, and transformer enclosure
- (4) A transformer or power supply meeting the requirements of 680.23(A)(2) with a primary rating not over 150 volts

**(B) Over the Low Voltage Contact Limit But Not over 150 Volts.** A lighting assembly without a transformer or power supply and with the luminaire lamp(s) operating at not over 150 volts shall be permitted to be cord-and-plug-connected where the assembly is listed as an assembly for the purpose. The installation shall comply with 680.23(A)(5), and the assembly shall have the following construction features:

- (1) No exposed metal parts
- (2) An impact-resistant polymeric lens and luminaire body
- (3) A ground-fault circuit interrupter with open neutral conductor protection as an integral part of the assembly

- (4) The luminaire lamp permanently connected to the ground-fault circuit interrupter with open-neutral protection
- (5) Compliance with the requirements of 680.23(A)

This requirement permits listed luminaire assemblies to be installed in or on storable pools. These assemblies are permitted to be cord-and-plug-connected to facilitate disconnection and removal when the storable pool is disassembled.

### 680.34 Receptacle Locations

Receptacles shall not be located less than 1.83 m (6 ft) from the inside walls of a pool. In determining these dimensions, the distance to be measured shall be the shortest path the supply cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, doorway with hinged or sliding door, window opening, or other effective permanent barrier.

## IV. Spas and Hot Tubs

### 680.40 General

Electrical installations at spas and hot tubs shall comply with the provisions of Part I and Part IV of this article.

### 680.41 Emergency Switch for Spas and Hot Tubs

A clearly labeled emergency shutoff or control switch for the purpose of stopping the motor(s) that provide power to

the recirculation system and jet system shall be installed at a point readily accessible to the users and not less than 1.5 m (5 ft) away, adjacent to, and within sight of the spa or hot tub. This requirement shall not apply to single-family dwellings.

The provisions of 680.41 require a local disconnecting device for spas and hot tubs that is capable of being used in an emergency. It is intended to address entrapment hazards associated with spas and hot tubs. The definitive publication on this issue, *Guideline for Entrapment Hazards: Making Pools and Spas Safer* (Pub. No. 363), is available from the U.S. Consumer Product Safety Commission, Washington, DC 20207, or on-line at [www.cpsc.gov](http://www.cpsc.gov).

The emergency shutoff switch must be installed within sight of and at least 5 ft from the spa or hot tub and must be clearly labeled “Emergency Shutoff.” See Exhibit 680.13 for an illustration of the switch location. The shutoff switch can be either a line-operated device or a remote-control circuit that causes the pump circuit to open. This requirement does not apply to one-family dwellings.

### 680.42 Outdoor Installations

A spa or hot tub installed outdoors shall comply with the provisions of Parts I and II of this article, except as permitted in 680.42(A) and (B), that would otherwise apply to pools installed outdoors.

The equipotential bonding requirements of 680.26, located in Part II of Article 680, are amended by 680.42(B) only for tubs with metal bands or hoops used to secure wooden staves

and for metal-to-metal mounting on a common base. All the other bonding requirements in 680.26 apply to outdoor spas and hot tubs, including the packaged and self-contained types.

**(A) Flexible Connections.** Listed packaged spa or hot tub equipment assemblies or self-contained spas or hot tubs utilizing a factory-installed or assembled control panel or panelboard shall be permitted to use flexible connections as covered in 680.42(A)(1) and (A)(2).

**(1) Flexible Conduit.** Liquidtight flexible metal conduit or liquidtight flexible nonmetallic conduit shall be permitted in lengths of not more than 1.8 m (6 ft) external to the spa or hot tub enclosure in addition to the length needed within the enclosure to make the electrical connection.

The use of liquidtight flexible metal or nonmetallic conduit is permitted by 680.42(A)(1) as a flexible wiring method to supply control panels or panelboards installed by the manufacturer in packaged or self-contained spas and hot tubs. The overall length of the flexible conduit is not limited but the portion of the conduit external to the spa or hot tub enclosure cannot exceed 6 ft. The external segment of the liquidtight conduit facilitates transition to a rigid wiring method or connection to an outlet or disconnecting means adjacent to the equipment.

**(2) Cord-and-Plug Connections.** Cord-and-plug connections with a cord not longer than 4.6 m (15 ft) shall be permitted where protected by a ground-fault circuit interrupter.

**EXHIBIT 680.13** Location of the emergency shutoff device required by 680.41.

**(B) Bonding.** Bonding by metal-to-metal mounting on a common frame or base shall be permitted. The metal bands or hoops used to secure wooden staves shall not be required to be bonded as required in 680.26.

**(C) Interior Wiring to Outdoor Installations.** In the interior of a one-family dwelling or in the interior of another building or structure associated with a one-family dwelling, any of the wiring methods recognized in Chapter 3 of this *Code* that contain a copper equipment grounding conductor that is insulated or enclosed within the outer sheath of the wiring method and not smaller than 12 AWG shall be permitted to be used for the connection to motor, heating, and control loads that are part of a self-contained spa or hot tub or a packaged spa or hot tub equipment assembly. Wiring to an underwater luminaire shall comply with 680.23 or 680.33.

### 680.43 Indoor Installations

A spa or hot tub installed indoors shall comply with the provisions of Parts I and II of this article except as modified by this section and shall be connected by the wiring methods of Chapter 3.

*Exception No. 1: Listed spa and hot tub packaged units rated 20 amperes or less shall be permitted to be cord-and-plug-connected to facilitate the removal or disconnection of the unit for maintenance and repair.*

*Exception No. 2: The equipotential bonding requirements for perimeter surfaces in 680.26(B)(2) shall not apply to a listed self-contained spa or hot tub installed above a finished floor.*

The equipotential bonding requirements of 680.26 apply to indoor spas and hot tubs through the requirement in 680.43 to follow the provisions of Parts I and II of Article 680. Section 680.26 is located in Part II. Exception No. 2 excludes listed self-contained spas and hot tubs from the perimeter surface bonding requirement specified in 680.26(B)(2) provided the unit sits on the finished floor and is not recessed or partially recessed in the finished floor.

**(A) Receptacles.** At least one 125-volt, 15- or 20-ampere receptacle on a general-purpose branch circuit shall be located not less than 1.83 m (6 ft) from, and not exceeding 3.0 m (10 ft) from, the inside wall of the spa or hot tub.

**(1) Location.** Receptacles shall be located at least 1.83 m (6 ft) measured horizontally from the inside walls of the spa or hot tub.

**(2) Protection, General.** Receptacles rated 125 volts and 30 amperes or less and located within 3.0 m (10 ft) of the

inside walls of a spa or hot tub shall be protected by a ground-fault circuit interrupter.

**(3) Protection, Spa or Hot Tub Supply Receptacle.** Receptacles that provide power for a spa or hot tub shall be ground-fault circuit-interrupter protected.

**(4) Measurements.** In determining the dimensions in this section addressing receptacle spacings, the distance to be measured shall be the shortest path the supply cord of an appliance connected to the receptacle would follow without piercing a floor, wall, ceiling, doorway with hinged or sliding door, window opening, or other effective permanent barrier.

### **(B) Installation of Luminaires, Lighting Outlets, and Ceiling-Suspended (Paddle) Fans.**

**(1) Elevation.** Luminaires, except as covered in 680.43(B)(2), lighting outlets, and ceiling-suspended (paddle) fans located over the spa or hot tub or within 1.5 m (5 ft) from the inside walls of the spa or hot tub shall comply with the clearances specified in (B)(1)(a), (B)(1)(b), and (B)(1)(c) above the maximum water level.

(a) *Without GFCI.* Where no GFCI protection is provided, the mounting height shall be not less than 3.7 m (12 ft).

(b) *With GFCI.* Where GFCI protection is provided, the mounting height shall be permitted to be not less than 2.3 m (7 ft 6 in.).

(c) *Below 2.3 m (7 ft 6 in.).* Luminaires meeting the requirements of item (1) or (2) and protected by a ground-fault circuit interrupter shall be permitted to be installed less than 2.3 m (7 ft 6 in.) over a spa or hot tub:

- (1) Recessed luminaires with a glass or plastic lens, nonmetallic or electrically isolated metal trim, and suitable for use in damp locations
- (2) Surface-mounted luminaires with a glass or plastic globe, a nonmetallic body, or a metallic body isolated from contact, and suitable for use in damp locations

**(2) Underwater Applications.** Underwater luminaires shall comply with the provisions of 680.23 or 680.33.

**(C) Switches.** Switches shall be located at least 1.5 m (5 ft), measured horizontally, from the inside walls of the spa or hot tub.

Receptacles, wall switches, and electrical devices and controls not associated with a spa or hot tub are required to be located at least 5 ft from the inside wall of the spa or hot tub. Receptacles within 10 ft are required to be protected by a

GFCI. Receptacles supplying power to a spa or hot tub are also required to be protected by a GFCI unless the unit is a listed package unit with integral GFCI protection.

Luminaires, lighting outlets, and ceiling-suspended (paddle) fans located less than 12 ft over a spa or hot tub and within 5 ft horizontally from the inside walls of the spa or hot tub are required to be protected by a GFCI.

**(D) Bonding.** The following parts shall be bonded together:

- (1) All metal fittings within or attached to the spa or hot tub structure
- (2) Metal parts of electrical equipment associated with the spa or hot tub water circulating system, including pump motors, unless part of a listed self-contained spa or hot tub

As part of the evaluation and listing of self-contained spas and hot tubs, the bonding covered by this requirement is to be performed by the manufacturer prior to the unit being installed at its final destination. For other than listed self-contained spas and hot tubs, the required bonding of non-current-carrying metal parts of electrical equipment associated with the water-circulating system, including the circulating pumps will be performed as part of the on-site installation in a similar fashion to permanently installed swimming pools.

- (3) Metal raceway and metal piping that are within 1.5 m (5 ft) of the inside walls of the spa or hot tub and that are not separated from the spa or hot tub by a permanent barrier
- (4) All metal surfaces that are within 1.5 m (5 ft) of the inside walls of the spa or hot tub and that are not separated from the spa or hot tub area by a permanent barrier

*Exception: Small conductive surfaces not likely to become energized, such as air and water jets and drain fittings, where not connected to metallic piping, towel bars, mirror frames, and similar nonelectrical equipment, shall not be required to be bonded.*

- 
- (5) Electrical devices and controls that are not associated with the spas or hot tubs and that are located less than 1.5 m (5 ft) from such units; otherwise, they shall be bonded to the spa or hot tub system

Bonding requirements for spas and hot tubs are similar to those in Parts I and II of Article 680, except that metal-to-

metal mounting on a common frame or base is an acceptable bonding method.

Small conductive surfaces such as air and water jets, drain fittings, and towel bars are not required to be bonded. See 680.43(D)(4), Exception.

**(E) Methods of Bonding.** All metal parts associated with the spa or hot tub shall be bonded by any of the following methods:

- (1) The interconnection of threaded metal piping and fittings
- (2) Metal-to-metal mounting on a common frame or base
- (3) The provisions of a solid copper bonding jumper, insulated, covered, or bare, not smaller than 8 AWG

**(F) Grounding.** The following equipment shall be grounded:

- (1) All electrical equipment located within 1.5 m (5 ft) of the inside wall of the spa or hot tub
- (2) All electrical equipment associated with the circulating system of the spa or hot tub

**(G) Underwater Audio Equipment.** Underwater audio equipment shall comply with the provisions of Part II of this article.

## 680.44 Protection

Except as otherwise provided in this section, the outlet(s) that supplies a self-contained spa or hot tub, a packaged spa or hot tub equipment assembly, or a field-assembled spa or hot tub shall be protected by a ground-fault circuit interrupter.

**(A) Listed Units.** If so marked, a listed self-contained unit or listed packaged equipment assembly that includes integral ground-fault circuit-interrupter protection for all electrical parts within the unit or assembly (pumps, air blowers, heaters, lights, controls, sanitizer generators, wiring, and so forth) shall be permitted without additional GFCI protection.

**(B) Other Units.** A field-assembled spa or hot tub rated 3 phase or rated over 250 volts or with a heater load of more than 50 amperes shall not require the supply to be protected by a ground-fault circuit interrupter.

- Informational Note: See 680.2 for definitions of *self-contained spa or hot tub* and for *packaged spa or hot tub equipment assembly*.

The requirements of 680.44 specify that field-assembled spas and hot tubs with heater loads of 50 amperes or less are

to be GFCI protected. Spas and hot tubs utilizing voltages over 250 volts or 3-phase power are not required to have GFCI protection because GFCI devices are not available in all voltage, amperage, and phasing arrangements.

## V. Fountains

Part V applies to permanently installed decorative fountains and reflecting pools in the ground, partially in the ground, or in a building. These units are primarily for aesthetic value and are not intended for swimming or wading.

Part V does not cover installations in natural lakes, rivers, or ponds. Such installations are covered by the requirements of Article 682, Natural and Artificially Made Bodies of Water.

### 680.50 General

The provisions of Part I and Part V of this article shall apply to all permanently installed fountains as defined in 680.2. Fountains that have water common to a pool shall additionally comply with the requirements in Part II of this article. Part V does not cover self-contained, portable fountains. Portable fountains shall comply with Parts II and III of Article 422.

### 680.51 Luminaires, Submersible Pumps, and Other Submersible Equipment

**(A) Ground-Fault Circuit Interrupter.** Luminaires, submersible pumps, and other submersible equipment, unless listed for operation at **low voltage contact limit** or less and supplied by a transformer or power supply that complies with 680.23(A)(2), shall be protected by a ground-fault circuit interrupter.

**(B) Operating Voltage.** No luminaires shall be installed for operation on supply circuits over 150 volts between conductors. Submersible pumps and other submersible equipment shall operate at 300 volts or less between conductors.

**(C) Luminaire Lenses.** Luminaires shall be installed with the top of the luminaire lens below the normal water level of the fountain unless listed for above-water locations. A luminaire facing upward shall comply with either (1) or (2):

- (1) Have the lens adequately guarded to prevent contact by any person
- (2) Be listed for use without a guard

**(D) Overheating Protection.** Electrical equipment that depends on submersion for safe operation shall be protected against overheating by a low-water cutoff or other approved means when not submerged.

**(E) Wiring.** Equipment shall be equipped with provisions for threaded conduit entries or be provided with a suitable flexible cord. The maximum length of each exposed cord in the fountain shall be limited to 3.0 m (10 ft). Cords extending beyond the fountain perimeter shall be enclosed in approved wiring enclosures. Metal parts of equipment in contact with water shall be of brass or other approved corrosion-resistant metal.

**(F) Servicing.** All equipment shall be removable from the water for relamping or normal maintenance. Luminaires shall not be permanently embedded into the fountain structure such that the water level must be reduced or the fountain drained for relamping, maintenance, or inspection.

**(G) Stability.** Equipment shall be inherently stable or be securely fastened in place.

### 680.52 Junction Boxes and Other Enclosures

**(A) General.** Junction boxes and other enclosures used for other than underwater installation shall comply with 680.24.

**(B) Underwater Junction Boxes and Other Underwater Enclosures.** Junction boxes and other underwater enclosures shall meet the requirements of 680.52(B)(1) and (B)(2).

#### (1) Construction.

(a) Underwater enclosures shall be equipped with provisions for threaded conduit entries or compression glands or seals for cord entry.

(b) Underwater enclosures shall be submersible and made of copper, brass, or other approved corrosion-resistant material.

**(2) Installation.** Underwater enclosure installations shall comply with (a) and (b).

(a) Underwater enclosures shall be filled with an approved potting compound to prevent the entry of moisture.

(b) Underwater enclosures shall be firmly attached to the supports or directly to the fountain surface and bonded as required. Where the junction box is supported only by conduits in accordance with 314.23(E) and (F), the conduits shall be of copper, brass, stainless steel, or other approved corrosion-resistant metal. Where the box is fed by nonmetallic conduit, it shall have additional supports and fasteners of copper, brass, or other approved corrosion-resistant material.

### 680.53 Bonding

All metal piping systems associated with the fountain shall be bonded to the equipment grounding conductor of the branch circuit supplying the fountain.

Informational Note: See 250.122 for sizing of these conductors.

### 680.54 Grounding

The following equipment shall be grounded:

- (1) Other than listed low-voltage luminaires not requiring grounding, all electrical equipment located within the fountain or within 1.5 m (5 ft) of the inside wall of the fountain
- (2) All electrical equipment associated with the recirculating system of the fountain
- (3) Panelboards that are not part of the service equipment and that supply any electrical equipment associated with the fountain

### 680.55 Methods of Grounding

**(A) Applied Provisions.** The provisions of 680.21(A), 680.23(B)(3), 680.23(F)(1) and (F)(2), 680.24(F), and 680.25 shall apply.

**(B) Supplied by a Flexible Cord.** Electrical equipment that is supplied by a flexible cord shall have all exposed non-current-carrying metal parts grounded by an insulated copper equipment grounding conductor that is an integral part of this cord. The equipment grounding conductor shall be connected to an equipment grounding terminal in the supply junction box, transformer enclosure, power supply enclosure, or other enclosure.

### 680.56 Cord-and-Plug-Connected Equipment

**(A) Ground-Fault Circuit Interrupter.** All electrical equipment, including power-supply cords, shall be protected by ground-fault circuit interrupters.

**(B) Cord Type.** Flexible cord immersed in or exposed to water shall be of a type for extra-hard usage, as designated in Table 400.4, and shall be a listed type with a “W” suffix.

**(C) Sealing.** The end of the flexible cord jacket and the flexible cord conductor termination within equipment shall be covered with, or encapsulated in, a suitable potting compound to prevent the entry of water into the equipment through the cord or its conductors. In addition, the ground connection within equipment shall be similarly treated to protect such connections from the deteriorating effect of water that may enter into the equipment.

**(D) Terminations.** Connections with flexible cord shall be permanent, except that grounding-type attachment plugs and receptacles shall be permitted to facilitate removal or disconnection for maintenance, repair, or storage of fixed or stationary equipment not located in any water-containing part of a fountain.

### 680.57 Signs

**(A) General.** This section covers electric signs installed within a fountain or within 3.0 m (10 ft) of the fountain edge.

**(B) Ground-Fault Circuit-Interrupter Protection for Personnel.** All circuits supplying the sign shall have ground-fault circuit-interrupter protection for personnel.

**(C) Location.**

**(1) Fixed or Stationary.** A fixed or stationary electric sign installed within a fountain shall be not less than 1.5 m (5 ft) inside the fountain measured from the outside edges of the fountain.

**(2) Portable.** A portable electric sign shall not be placed within a pool or fountain or within 1.5 m (5 ft) measured horizontally from the inside walls of the fountain.

**(D) Disconnect.** A sign shall have a local disconnecting means in accordance with 600.6 and 680.12.

**(E) Bonding and Grounding.** A sign shall be grounded and bonded in accordance with 600.7.

The use of electric signs in fountains has become increasingly popular. Electric signs in fountains are required to have GFCI protection for personnel. This protection may be provided in the feeder or branch circuit. To prevent contact by persons around the fountain, the sign must be at least 5 ft from the edge of the fountain (see Exhibit 680.14). Disconnecting and bonding requirements in Article 600 apply, and grounding must be provided in accordance with Article 250.

**EXHIBIT 680.14** Electric sign located in a fountain as described in 680.57.

### 680.58 GFCI Protection for Adjacent Receptacle Outlets

All 15- or 20-ampere, single-phase 125-volt through 250-volt receptacles located within 6.0 m (20 ft) of a fountain edge shall be provided with GFCI protection.

## VI. Pools and Tubs for Therapeutic Use

Part VI recognizes therapeutic equipment in other locations, such as athletic training rooms and health care facilities, where conditions of use are the same or similar. Portable therapeutic appliances, which are covered by the provisions of Article 422, are required to provide protection from electrocution while in the “on” or “off” position. The device used is an immersion-detection circuit interrupter (IDCI).

Permanently installed therapeutic pools that cannot be readily disassembled are required to comply with Parts I and II of Article 680. The limitations regarding luminaires over and around a swimming pool do not apply to therapeutic pools and tubs. Luminaires in the tub area are required to be totally enclosed, and therapeutic tubs that cannot easily be moved are subject to the same basic requirements.

Bonding and grounding requirements are similar to those in Parts I and II of Article 680, except that metal-to-metal mounting on a common frame or base is permitted. Where equipment is connected by a flexible cord, the equipment grounding conductor is required to be connected to a fixed metal part of the assembly.

### 680.60 General

The provisions of Part I and Part VI of this article shall apply to pools and tubs for therapeutic use in health care facilities, gymnasiums, athletic training rooms, and similar areas. Portable therapeutic appliances shall comply with Parts II and III of Article 422.

Informational Note: See 517.2 for definition of health care facilities.

### 680.61 Permanently Installed Therapeutic Pools

Therapeutic pools that are constructed in the ground, on the ground, or in a building in such a manner that the pool cannot be readily disassembled shall comply with Parts I and II of this article.

*Exception: The limitations of 680.22(B)(1) through (C)(4) shall not apply where all luminaires are of the totally enclosed type.*

### 680.62 Therapeutic Tubs (Hydrotherapeutic Tanks)

Therapeutic tubs, used for the submersion and treatment of patients, that are not easily moved from one place to another

in normal use or that are fastened or otherwise secured at a specific location, including associated piping systems, shall conform to Part VI.

**(A) Protection.** Except as otherwise provided in this section, the outlet(s) that supplies a self-contained therapeutic tub or hydrotherapeutic tank, a packaged therapeutic tub or hydrotherapeutic tank, or a field-assembled therapeutic tub or hydrotherapeutic tank shall be protected by a ground-fault circuit interrupter.

**(1) Listed Units.** If so marked, a listed self-contained unit or listed packaged equipment assembly that includes integral ground-fault circuit-interrupter protection for all electrical parts within the unit or assembly (pumps, air blowers, heaters, lights, controls, sanitizer generators, wiring, and so forth) shall be permitted without additional GFCI protection.

**(2) Other Units.** A therapeutic tub or hydrotherapeutic tank rated 3 phase or rated over 250 volts or with a heater load of more than 50 amperes shall not require the supply to be protected by a ground-fault circuit interrupter.

The requirements in 680.62(A)(2) for large therapeutic tanks and therapeutic tubs are similar to the requirements for large hot tubs and spas. Large field-assembled therapeutic tubs are not required to have GFCI protection in their electrical supply when the heater load is over 50 amperes.

**(B) Bonding.** The following parts shall be bonded together:

- (1) All metal fittings within or attached to the tub structure
- (2) Metal parts of electrical equipment associated with the tub water circulating system, including pump motors
- (3) Metal-sheathed cables and raceways and metal piping that are within 1.5 m (5 ft) of the inside walls of the tub and not separated from the tub by a permanent barrier
- (4) All metal surfaces that are within 1.5 m (5 ft) of the inside walls of the tub and not separated from the tub area by a permanent barrier
- (5) Electrical devices and controls that are not associated with the therapeutic tubs and located within 1.5 m (5 ft) from such units.

*Exception: Small conductive surfaces not likely to become energized, such as air and water jets and drain fittings not connected to metallic piping, and towel bars, mirror frames, and similar nonelectrical equipment not connected to metal framing, shall not be required to be bonded.*

**(C) Methods of Bonding.** All metal parts required to be bonded by this section shall be bonded by any of the following methods:

- (1) The interconnection of threaded metal piping and fittings
- (2) Metal-to-metal mounting on a common frame or base
- (3) Connections by suitable metal clamps
- (4) By the provisions of a solid copper bonding jumper, insulated, covered, or bare, not smaller than 8 AWG

#### (D) Grounding.

**(1) Fixed or Stationary Equipment.** The equipment specified in (a) and (b) shall be connected to the equipment grounding conductor.

(a) *Location.* All electrical equipment located within 1.5 m (5 ft) of the inside wall of the tub shall be connected to the equipment grounding conductor.

(b) *Circulation System.* All electrical equipment associated with the circulating system of the tub shall be connected to the equipment grounding conductor.

**(2) Portable Equipment.** Portable therapeutic appliances shall meet the grounding requirements in 250.114.

**(E) Receptacles.** All receptacles within 1.83 m (6 ft) of a therapeutic tub shall be protected by a ground-fault circuit interrupter.

**(F) Luminaires.** All luminaires used in therapeutic tub areas shall be of the totally enclosed type.

## VII. Hydromassage Bathtubs

### 680.70 General

Hydromassage bathtubs as defined in 680.2 shall comply with Part VII of this article. They shall not be required to comply with other parts of this article.

### 680.71 Protection

Hydromassage bathtubs and their associated electrical components shall be on an individual branch circuit(s) and protected by a readily accessible ground-fault circuit interrupter. All 125-volt, single-phase receptacles not exceeding 30 amperes and located within 1.83 m (6 ft) measured horizontally of the inside walls of a hydromassage tub shall be protected by a ground-fault circuit interrupter.

Hydromassage bathtubs (see definition in 680.2) are required to be protected by a GFCI. In addition, all 125-volt, single-phase, 15-, 20-, and 30-ampere receptacles within 5 ft of the inside wall of the hydromassage bathtub are required to be GFCI protected. Hydromassage bathtubs are treated the same as ordinary bathtubs in regard to the installation of luminaires, switches, and other electrical equipment.

See 410.10(D) for special requirements relating to cord-connected luminaires, hanging luminaires, and pendants near bathtubs. Also see 210.8(A)(1) and (B)(1) for requirements for GFCI protection of bathroom receptacles. The GFCI device protecting the hydromassage bathtub is required to be readily accessible. Where the GFCI device is installed in the space under a hydromassage bathtub, the opening to that space must provide the ready access that is now specifically required.

### 680.72 Other Electrical Equipment

Luminaires, switches, receptacles, and other electrical equipment located in the same room, and not directly associated with a hydromassage bathtub, shall be installed in accordance with the requirements of Chapters 1 through 4 in this *Code* covering the installation of that equipment in bathrooms.

### 680.73 Accessibility

Hydromassage bathtub electrical equipment shall be accessible without damaging the building structure or building finish. Where the hydromassage bathtub is cord- and plug-connected with the supply receptacle accessible only through a service access opening, the receptacle shall be installed so that its face is within direct view and not more than 300 mm (1 ft) of the opening.

Section 680.73 requires access to electrical equipment associated with a hydromassage tub. Building codes and plumbing codes might not require access to this equipment. This requirement is intended to ensure that the electrical equipment associated with hydromassage bathtubs can be accessed for maintenance and repair without damaging the finish or structure of the building. For cord-and-plug-connected units, access to the receptacle supplying the unit has to provide direct visual contact with the face of the receptacle (as opposed to the back of the outlet box in which it is installed), and it has to be located not more than 1 ft from any point of the opening. Where a ground-fault circuit-interrupter type receptacle is installed in this location, the receptacle is required to be readily accessible by 680.71. Access may be either an integral part of the tub or one that is provided in the finish that encloses the tub. Where utilization equipment associated with a hydromassage bathtub is cord- and plug-connected, 680.73 requires the receptacle to be installed within 1 ft of the access opening and positioned so that the face of the receptacle is visible. This requirement facilitates connection and disconnection of the cord- and plug-connected equipment. Exhibit 680.15 shows a receptacle for a cord- and plug-connected hydromassage bathtub positioned to meet the requirement in 680.73.

**EXHIBIT 680.15** Hydromassage bathtub circulating pump motor and supply receptacle located per 680.73. (Courtesy of the International Association of Electrical Inspectors)

### 680.74 Bonding

All metal piping systems and all grounded metal parts in contact with the circulating water shall be bonded together using a solid copper bonding jumper, insulated, covered, or bare, not smaller than 8 AWG. The bonding jumper shall be connected to the terminal on the circulating pump motor that is intended for this purpose. The bonding jumper shall not be required to be connected to a double insulated circulating pump motor. The 8 AWG or larger solid copper bonding jumper shall be required for equipotential bonding in the area of the hydromassage bathtub and shall not be required to be extended or attached to any remote panelboard, service equipment, or any electrode. The 8 AWG or larger solid copper bonding jumper shall be long enough to terminate on a replacement non-double-insulated pump motor and shall be terminated to the equipment grounding conductor of the branch circuit of the motor when a double-insulated circulating pump motor is used.

The bonding requirement for hydromassage bathtubs requires interconnection between metal piping systems and metal parts associated with the water recirculation system only at the hydromassage bathtub location. As is the case with swimming pool bonding, this section does not require the installation of a bonding conductor from the hydromassage bathtub pump motor to the service equipment or panelboard from which the hydromassage bathtub branch circuit originates even if there is no metal piping or metal parts in the vicinity of the hydromassage bathtub.

The requirements of 680.74 provide equipotential bonding in the immediate vicinity of the hydromassage unit, and

the equipment grounding conductor of the branch circuit supplying the hydromassage tub provides the path for ground-fault current. As is the case with other bonding requirements in Article 680, the 8 AWG copper bonding conductor is required to be a solid conductor. Solid conductors are required for Article 680 equipotential bonding applications in order to provide an added level of resistance to physical damage.

Double-insulated circulating pump motors are not permitted to be bonded. However, as is the case in 680.26(B)(6) (a) for swimming pools, where a double-insulated water circulating pump motor is used and there are other metal objects associated with the water circulating system that are required to be bonded, a solid, 8 AWG or larger copper bonding conductor is to be run to the pump location with suitable length to connect it to a replacement pump that is not double insulated. In addition, during the period of time that the double-insulated pump is in service, the bonding conductor is required to be connected to the equipment grounding conductor of the branch circuit supplying the hydromassage bathtub pump motor.

## ARTICLE 682 Natural and Artificially Made Bodies of Water

## I. General

### 682.1 Scope

This article applies to the installation of electrical wiring for, and equipment in and adjacent to, natural or artificially made bodies of water not covered by other articles in this *Code*, such as but not limited to aeration ponds, fish farm ponds, storm retention basins, treatment ponds, irrigation (channels) facilities.

The scope of Article 680 does not include bodies of water other than those described in 680.1 and defined in 680.2.

Electrical equipment such as pumps, luminaires, and their associated supply wiring are frequently installed in lakes, ponds, aeration and treatment basins, and similar bodies of water, and the requirements in Article 682 are designed to minimize the shock hazards inherent in those wet and damp locations. Safety concepts contained in the requirements of Articles 553, 555, 590, and 680 provide the foundation for the requirements in Article 682.

### 682.2 Definitions

**Artificially Made Bodies of Water.** Bodies of water that have been constructed or modified to fit some decorative or commercial purpose such as, but not limited to, aeration ponds, fish farm ponds, storm retention basins, treatment ponds, and irrigation (channel) facilities. Water depths may vary seasonally or be controlled.

The term *artificially made bodies of water* includes all bodies of water that are not naturally created and that are not covered by the requirements of Article 680. The uses of artificially made bodies of water include decorative, agricultural, municipal infrastructure, and industrial. The decorative pond shown in Exhibit 682.1 is an example of an artificially made body of water because it was constructed and filled with water and did not occur naturally.

**Electrical Datum Plane.** The electrical datum plane as used in this article is defined as follows:

- (1) In land areas subject to tidal fluctuation, the electrical datum plane is a horizontal plane 600 mm (2 ft) above the highest tide level for the area occurring under normal circumstances, that is, highest high tide.

**EXHIBIT 682.1** An artificially made body of water. The electrical equipment associated with pumps used to circulate water in this artificial pond is subject to the requirements of Article 682.

- (2) In land areas not subject to tidal fluctuation, the electrical datum plane is a horizontal plane 600 mm (2 ft) above the highest water level for the area occurring under normal circumstances.
- (3) In land areas subject to flooding, the electrical datum plane based on (1) or (2) above is a horizontal plane 600 mm (2 ft) above the point identified as the prevailing high water mark or an equivalent benchmark based on seasonal or storm-driven flooding from the authority having jurisdiction.
- (4) The electrical datum plane for floating structures and landing stages that are (1) installed to permit rise and fall response to water level, without lateral movement, and (2) that are so equipped that they can rise to the datum plane established for (1) or (2) above, is a horizontal plane 750 mm (30 in.) above the water level at the floating structure or landing stage and a minimum of 300 mm (12 in.) above the level of the deck.

See the commentary on the electrical datum plane in 555.2.

**Equipotential Plane.** An area where wire mesh or other conductive elements are on, embedded in, or placed under the walk surface within 75 mm (3 in.), bonded to all metal structures and fixed nonelectrical equipment that may become energized, and connected to the electrical grounding system to prevent a difference in voltage from developing within the plane.

**Natural Bodies of Water.** Bodies of water such as lakes, streams, ponds, rivers, and other naturally occurring bodies of water, which may vary in depth throughout the year.

**Shoreline.** The farthest extent of standing water under the applicable conditions that determine the electrical datum plane for the specified body of water.

### 682.3 Other Articles

If the water is subject to boat traffic, the wiring shall comply with 555.13(B).

## II. Installation

### 682.10 Electrical Equipment and Transformers

Electrical equipment and transformers, including their enclosures, shall be specifically approved for the intended location. No portion of an enclosure for electrical equipment not identified for operation while submerged shall be located below the electrical datum plane.

See 640.10 for requirements covering the installation of audio system equipment near a body of water.

### 682.11 Location of Service Equipment

On land, the service equipment for floating structures and submersible electrical equipment shall be located no closer than 1.5 m (5 ft) horizontally from the shoreline and live parts shall be elevated a minimum of 300 mm (12 in.) above the electrical datum plane. Service equipment shall disconnect when the water level reaches the height of the established electrical datum plane.

### 682.12 Electrical Connections

All electrical connections not intended for operation while submerged shall be located at least 300 mm (12 in.) above the deck of a floating or fixed structure, but not below the electrical datum plane.

### 682.13 Wiring Methods and Installation

Liquidtight flexible metal conduit or liquidtight flexible nonmetallic conduit with approved fittings shall be permitted for feeders and where flexible connections are required for services. Extra-hard usage portable power cable listed for both wet locations and sunlight resistance shall be permitted for a feeder or a branch circuit where flexibility is required. Other wiring methods suitable for the location shall be permitted to be installed where flexibility is not required. Temporary wiring in accordance with 590.4 shall be permitted.

### 682.14 Submersible or Floating Equipment Power Connection(s)

Submersible or floating equipment shall be cord- and plug-connected, using extra-hard usage cord, as designated in

Table 400.4, and listed with a “W” suffix. The plug and receptacle combination shall be arranged to be suitable for the location while in use. Disconnecting means shall be provided to isolate each submersible or floating electrical equipment from its supply connection(s) without requiring the plug to be removed from the receptacle.

*Exception: Equipment listed for direct connection and equipment anchored in place and incapable of routine movement caused by water currents or wind shall be permitted to be connected using wiring methods covered in 682.13.*

**(A) Type and Marking.** The disconnecting means shall consist of a circuit breaker, a switch, or both, or a molded case switch, and shall be specifically marked to designate which receptacle or other outlet it controls.

**(B) Location.** The disconnecting means shall be readily accessible on land, located not more than 750 mm (30 in.) from the receptacle it controls, and shall be located in the supply circuit ahead of the receptacle. The disconnecting means shall be located within sight of but not closer than 1.5 m (5 ft) from the shoreline and shall be elevated not less than 300 mm (12 in.) above the datum plane.

The general requirement on connecting submersible and floating equipment is that a cord-and-plug connection be provided, and only under the conditions specified in the exception is equipment permitted to be direct-connected (hard-wired). However, the separable connection is not permitted to serve as the required disconnecting means for the submersible or floating equipment. One of the types of disconnecting means described in 682.14(A) has to be provided for each piece of submersible or floating equipment so that power can be turned off without having to separate the cord cap from the receptacle. The disconnecting means has to be located within 30 in. of the receptacle that it controls and be installed not less than 12 in. above the datum plane. In addition, the location of the disconnecting means cannot be closer than 5 ft horizontally from the shoreline. See 682.2 for the definitions of *datum plane* and *shoreline*. In the case of tidal waters, the amount of fluctuation between low and high tides has a direct impact on the datum plane and shoreline benchmarks and consequently, on the length of the flexible cord from the receptacle to the floating or submersible equipment.

### 682.15 Ground-Fault Circuit-Interrupter (GFCI) Protection

Fifteen- and 20-ampere single-phase, 125-volt through 250-volt receptacles installed outdoors and in or on floating

buildings or structures within the electrical datum plane area that are used for storage, maintenance, or repair where portable electric hand tools, electrical diagnostic equipment, or portable lighting equipment are to be used shall be provided with GFCI protection. The GFCI protection device shall be located not less than 300 mm (12 in.) above the established electrical datum plane.

### III. Grounding and Bonding

#### 682.30 Grounding

Wiring and equipment within the scope of this article shall be grounded as specified in Part III of 553, 555.15, and with the requirements in Part III of this article.

#### 682.31 Equipment Grounding Conductors

**(A) Type.** Equipment grounding conductors shall be insulated copper conductors sized in accordance with 250.122 but not smaller than 12 AWG.

**(B) Feeders.** Where a feeder supplies a remote panelboard or other distribution equipment, an insulated equipment grounding conductor shall extend from a grounding terminal in the service to a grounding terminal and busbar in the remote panelboard or other distribution equipment.

**(C) Branch Circuits.** The insulated equipment grounding conductor for branch circuits shall terminate at a grounding terminal in a remote panelboard or other distribution equipment or the grounding terminal in the main service equipment.

**(D) Cord-and-Plug-Connected Appliances.** Where grounded, cord-and-plug-connected appliances shall be grounded by means of an equipment grounding conductor in the cord and a grounding-type attachment plug.

#### 682.32 Bonding of Non-Current-Carrying Metal Parts

All metal parts in contact with the water, all metal piping, tanks, and all non-current-carrying metal parts that are likely to become energized shall be bonded to the grounding terminal in the distribution equipment.

#### 682.33 Equipotential Planes and Bonding of Equipotential Planes

An equipotential plane shall be installed where required in this section to mitigate step and touch voltages at electrical equipment.

**(A) Areas Requiring Equipotential Planes.** Equipotential planes shall be installed adjacent to all outdoor service equipment or disconnecting means that control equipment in

or on water, that have a metallic enclosure and controls accessible to personnel, and that are likely to become energized. The equipotential plane shall encompass the area around the equipment and shall extend from the area directly below the equipment out not less than 900 mm (36 in.) in all directions from which a person would be able to stand and come in contact with the equipment.

**(B) Areas Not Requiring Equipotential Planes.** Equipotential planes shall not be required for the controlled equipment supplied by the service equipment or disconnecting means. All circuits rated not more than 60 amperes at 120 through 250 volts, single phase, shall have GFCI protection.

**(C) Bonding.** Equipotential planes shall be bonded to the electrical grounding system. The bonding conductor shall be solid copper, insulated, covered or bare, and not smaller than 8 AWG. Connections shall be made by exothermic welding or by listed pressure connectors or clamps that are labeled as being suitable for the purpose and are of stainless steel, brass, copper, or copper alloy.

## ARTICLE 685 Integrated Electrical Systems

### Contents

- I. General
  - 685.1 Scope
  - 685.3 Application of Other Articles
- II. Orderly Shutdown
  - 685.10 Location of Overcurrent Devices in or on Premises
  - 685.12 Direct-Current System Grounding
  - 685.14 Ungrounded Control Circuits

### I. General

#### 685.1 Scope

This article covers integrated electrical systems, other than unit equipment, in which orderly shutdown is necessary to ensure safe operation. An *integrated electrical system* as used in this article is a unitized segment of an industrial wiring system where all of the following conditions are met:

- (1) An orderly shutdown is required to minimize personnel hazard and equipment damage.
- (2) The conditions of maintenance and supervision ensure that qualified persons service the system. The name(s) of the qualified person(s) shall be kept in a permanent record at the office of the establishment in charge of the completed installation.

A person designated as a qualified person shall possess the skills and knowledge related to the construction and operation of the electrical equipment and installation and shall have received documented safety training on the hazards involved. Documentation of their qualifications shall be on file with the office of the establishment in charge of the completed installation.

- (3) Effective safeguards acceptable to the authority having jurisdiction are established and maintained.

The integrated electrical systems commonly used in large and complex industrial processes are designed, installed, and operated under stringent on-site engineering supervision. The control equipment, including overcurrent devices, is located so that it is accessible to qualified personnel, but that location might not meet and is not required to meet the conditions described in the Article 100 definition of *readily accessible*. Locating overcurrent devices and their associated disconnecting means so that it is not readily accessible to unqualified personnel is one of the preventative measures used to help maintain continuity of operation.

For some industrial processes, the sudden loss of electric power to vital equipment is an unacceptable level of risk, and an orderly shutdown procedure is necessary to prevent severe equipment damage, injury to personnel, or, in some extreme cases, catastrophic failure. Orderly shutdown is commonly employed in nuclear power-generating facilities, paper mills, and other areas with hazardous processes.

### 685.3 Application of Other Articles

The articles/sections in Table 685.3 apply to particular cases of installation of conductors and equipment, where there are orderly shutdown requirements that are in addition to those of this article or are modifications of them.

## II. Orderly Shutdown

### 685.10 Location of Overcurrent Devices in or on Premises

Location of overcurrent devices that are critical to integrated electrical systems shall be permitted to be accessible, with mounting heights permitted to ensure security from operation by unqualified personnel.

### 685.12 Direct-Current System Grounding

Two-wire dc circuits shall be permitted to be ungrounded.

### 685.14 Ungrounded Control Circuits

Where operational continuity is required, control circuits of 150 volts or less from separately derived systems shall be permitted to be ungrounded.

## I. General

### 690.1 Scope

The provisions of this article apply to solar photovoltaic (PV) electrical energy systems, including the array circuit(s), inverter(s), and controller(s) for such systems. [See Figure 690.1(A) and Figure 690.1(B).] Solar photovoltaic systems covered by this article may be interactive with other electrical power production sources or stand-alone, with or without electrical energy storage such as batteries. These systems may have ac or dc output for utilization.

The use of photovoltaic (PV) systems as utility-interactive or stand-alone power-supply systems has steadily increased as the technology and availability of PV equipment have evolved. Also, recently passed legislation that provides financial incentives to end users has resulted in the burgeoning use of these system in residential, commercial, institutional, and industrial settings. The requirements of Article 690 cover the use of stand-alone and utility-interactive PV systems. Utility-interactive photovoltaic systems are subject to the requirements for interconnected electric power production sources contained in Article 705.

Exhibit 690.1 shows a custom-designed home with a PV electrical system. The integrated array of glass panels on the roof generates electricity directly from the sun using PV modules.

### 690.2 Definitions

**Alternating-Current (ac) Module (Alternating-Current Photovoltaic Module).** A complete, environmentally protected unit consisting of solar cells, optics, inverter, and other components, exclusive of tracker, designed to generate ac power when exposed to sunlight.

#### Notes:

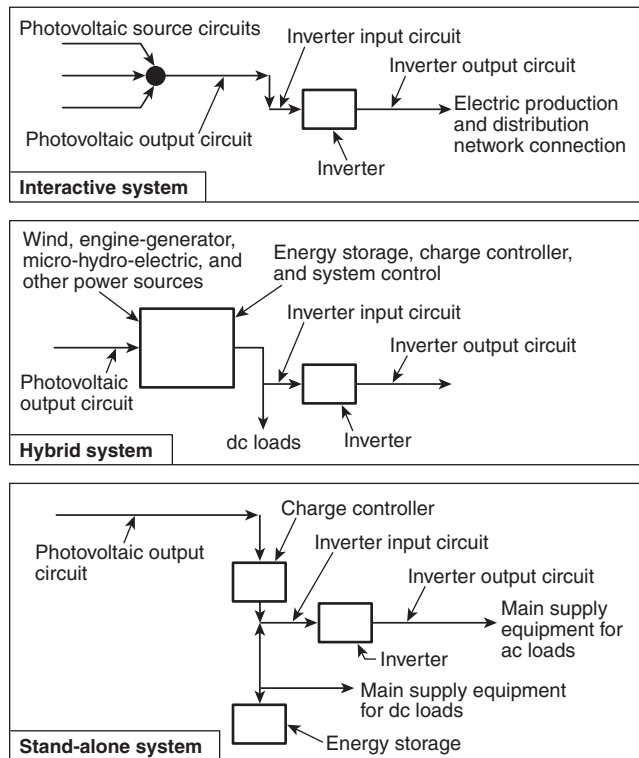

1. These diagrams are intended to be a means of identification for photovoltaic system components, circuits, and connections.
2. Disconnecting means required by Article 690, Part III, are not shown.
3. System grounding and equipment grounding are not shown. See Article 690, Part V.

**FIGURE 690.1(A) Identification of Solar Photovoltaic System Components.**

**EXHIBIT 690.1** Roof of a solar house that in the Northern Hemisphere typically faces south to maximize exposure. (Courtesy of Solar Design Associates, Inc.)

An ac PV module consists of a single integrated mechanical unit. Because there is no accessible, field-installed dc wiring in this single unit, the dc PV source-circuit requirements in

## Notes:

1. These diagrams are intended to be a means of identification for photovoltaic system components, circuits, and connections.
2. Disconnecting means and overcurrent protection required by Article 690 are not shown.
3. System grounding and equipment grounding are not shown. See Article 690, Part V.
4. Custom designs occur in each configuration, and some components are optional.

**FIGURE 690.1(B) Identification of Solar Photovoltaic System Components in Common System Configurations.**

this *Code* are not applicable to the dc wiring in an ac PV module.

**Array.** A mechanically integrated assembly of modules or panels with a support structure and foundation, tracker, and other components, as required, to form a direct-current power-producing unit.

A rooftop photovoltaic array is illustrated in Exhibit 690.2.

**Bipolar Photovoltaic Array.** A photovoltaic array that has two outputs, each having opposite polarity to a common reference point or center tap.

**Blocking Diode.** A diode used to block reverse flow of current into a photovoltaic source circuit.

**EXHIBIT 690.2** An array composed of multiple modules or panels installed on a support structure and foundation. (Courtesy of NECA)

Blocking diodes are not required by this *Code*, although the instructions or labels supplied with the PV module may require them. Blocking diodes are not overcurrent devices and may not be substituted for any overcurrent device required by this *Code*.

**Building Integrated Photovoltaics.** Photovoltaic cells, devices, modules, or modular materials that are integrated into the outer surface or structure of a building and serve as the outer protective surface of that building.

**Charge Controller.** Equipment that controls dc voltage or dc current, or both, used to charge a battery.

**Diversion Charge Controller.** Equipment that regulates the charging process of a battery by diverting power from energy storage to direct-current or alternating-current loads or to an interconnected utility service.

**Electrical Production and Distribution Network.** A power production, distribution, and utilization system, such as a utility system and connected loads, that is external to and not controlled by the photovoltaic power system.

**Hybrid System.** A system comprised of multiple power sources. These power sources may include photovoltaic, wind, micro-hydro generators, engine-driven generators, and others, but do not include electrical production and distribution network systems. Energy storage systems, such as batteries, do not constitute a power source for the purpose of this definition.

**Interactive System.** A solar photovoltaic system that operates in parallel with and may deliver power to an electrical

production and distribution network. For the purpose of this definition, an energy storage subsystem of a solar photovoltaic system, such as a battery, is not another electrical production source.

**Inverter.** Equipment that is used to change voltage level or waveform, or both, of electrical energy. Commonly, an inverter [also known as a power conditioning unit (PCU) or power conversion system (PCS)] is a device that changes dc input to an ac output. Inverters may also function as battery chargers that use alternating current from another source and convert it into direct current for charging batteries.

**Inverter Input Circuit.** Conductors between the inverter and the battery in stand-alone systems or the conductors between the inverter and the photovoltaic output circuits for electrical production and distribution network.

**Inverter Output Circuit.** Conductors between the inverter and an ac panelboard for stand-alone systems or the conductors between the inverter and the service equipment or another electric power production source, such as a utility, for electrical production and distribution network.

**Module.** A complete, environmentally protected unit consisting of solar cells, optics, and other components, exclusive of tracker, designed to generate dc power when exposed to sunlight.

**Monopole Subarray.** A PV subarray that has two conductors in the output circuit, one positive (+) and one negative (–). Two monopole PV subarrays are used to form a bipolar PV array.

**Panel.** A collection of modules mechanically fastened together, wired, and designed to provide a field-installable unit.

**Photovoltaic Output Circuit.** Circuit conductors between the photovoltaic source circuit(s) and the inverter or dc utilization equipment.

**Photovoltaic Power Source.** An array or aggregate of arrays that generates dc power at system voltage and current.

**Photovoltaic Source Circuit.** Circuits between modules and from modules to the common connection point(s) of the dc system.

**Photovoltaic System Voltage.** The direct current (dc) voltage of any photovoltaic source or photovoltaic output circuit. For multiwire installations, the photovoltaic system voltage is the highest voltage between any two dc conductors.

**Solar Cell.** The basic photovoltaic device that generates electricity when exposed to light.

**Solar Photovoltaic System.** The total components and subsystems that, in combination, convert solar energy

into electric energy suitable for connection to a utilization load.

**Stand-Alone System.** A solar photovoltaic system that supplies power independently of an electrical production and distribution network.

The simplified circuit schematics in Exhibits 690.3 through 690.6 demonstrate the use of various components in a PV system. Specific requirements for overcurrent protection, disconnecting means, and grounding are covered in other sections of Article 690 and should not be assumed based on these drawings. Instructions for, or labels on the PV module might require additional overcurrent devices that may not be shown.

**Subarray.** An electrical subset of a PV array.

### 690.3 Other Articles

Wherever the requirements of other articles of this *Code* and Article 690 differ, the requirements of Article 690 shall apply and, if the system is operated in parallel with a primary source(s) of electricity, the requirements in 705.14, 705.16, 705.32, and 705.143 shall apply.

*Exception:* Solar photovoltaic systems, equipment, or wiring installed in a hazardous (classified) location shall also comply with the applicable portions of Articles 500 through 516.

### 690.4 Installation

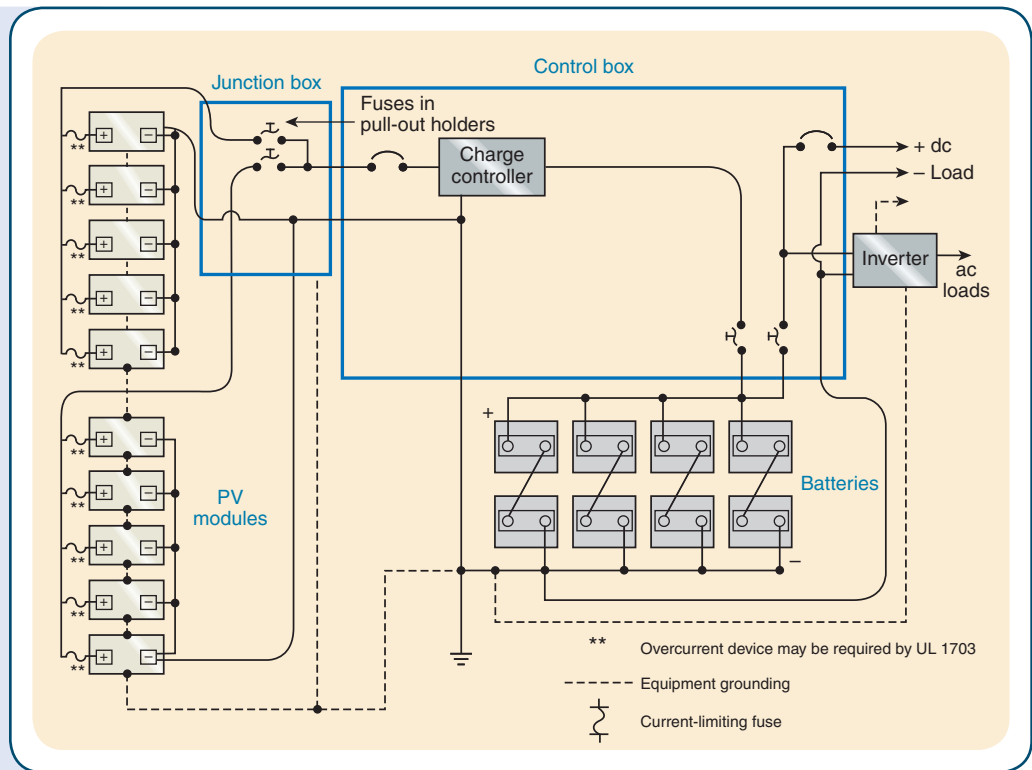

**(A) Photovoltaic Systems.** Photovoltaic systems shall be permitted to supply a building or other structure in addition to any other electricity supply system(s).

**(B) Identification and Grouping.** Photovoltaic source circuits and PV output circuits shall not be contained in the same raceway, cable tray, cable, outlet box, junction box, or similar fitting as conductors, feeders, or branch circuits of other non-PV systems, unless the conductors of the different systems are separated by a partition. Photovoltaic system conductors shall be identified and grouped as required by 690.4(B)(1) through (4). The means of identification shall be permitted by separate color coding, marking tape, tagging, or other approved means.

Section 690.4(B) does not permit the alternating-current branch-circuit conductors that supply an exterior luminaire installed near a roof-mounted PV array to share the same raceway or cable with the conductors of PV source circuits or PV output circuits.

**EXHIBIT 690.3** Simplified circuit schematic of a small residential stand-alone system.

Conductors directly related to a specific PV system, such as those in dc and ac output power circuits, may be contained in the same raceway as PV source and output conductors, providing they meet the requirements of 690.4(B) (1) through (B)(4) and 300.3(C).

**(1) Photovoltaic Source Circuits.** Photovoltaic source circuits shall be identified at all points of termination, connection, and splices.

**(2) Photovoltaic Output and Inverter Circuits.** The conductors of PV output circuits and inverter input and output circuits shall be identified at all points of termination, connection, and splices.

**(3) Conductors of Multiple Systems.** Where the conductors of more than one PV system occupy the same junction box, raceway, or equipment, the conductors of each system shall be identified at all termination, connection, and splice points.

*Exception:* Where the identification of the conductors is evident by spacing or arrangement, further identification is not required.

**(4) Grouping.** Where the conductors of more than one PV system occupy the same junction box or raceway with a re-

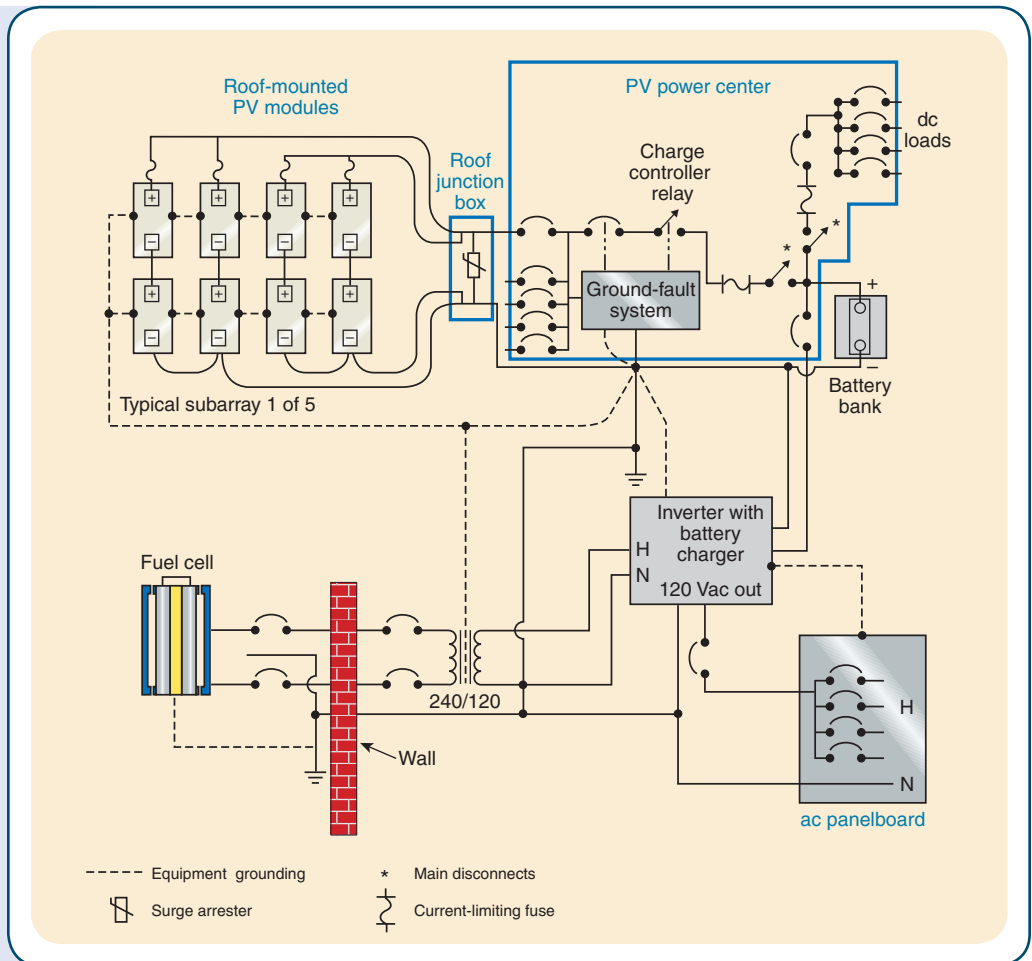

movable cover(s), the ac and dc conductors of each system shall be grouped separately by wire ties or similar means at least once, and then shall be grouped at intervals not to exceed 1.8 m (6 ft).

*Exception:* The requirement for grouping shall not apply if the circuit enters from a cable or raceway unique to the circuit that makes the grouping obvious.

**(C) Module Connection Arrangement.** The connection to a module or panel shall be arranged so that removal of a module or panel from a photovoltaic source circuit does not interrupt a grounded conductor to other PV source circuits.

In general, 690.4(C) requires that a jumper be installed between a module terminal or lead and the connection point to the grounded PV source-circuit conductor. That way, a module can be removed without interrupting the grounded conductor to other PV source circuits. If interrupted, such conductors, although identified as grounded, would be operating at the system potential with respect to ground, and a shock hazard could result. The reverse-current protection requirement on nearly all PV modules (as indicated by the fuse requirement labeled on the back of each module) generally dictates that each module or string of modules have a series overcurrent device and become a source circuit.

**EXHIBIT 690.4** Simplified circuit schematic of a medium-sized residential hybrid system.

**(D) Equipment.** Inverters, motor generators, photovoltaic modules, photovoltaic panels, ac photovoltaic modules, source-circuit combiners, and charge controllers intended for use in photovoltaic power systems shall be identified and listed for the application.

Section 690.4(D) requires equipment used in PV systems to be listed for the application. Equipment listed for marine, mobile, telecommunications, or other applications may not be suitable for installation in permanent PV power systems complying with this *Code*.

**(E) Wiring and Connections.** The equipment and systems in 690.4(A) through (D) and all associated wiring and interconnections shall be installed only by qualified persons.

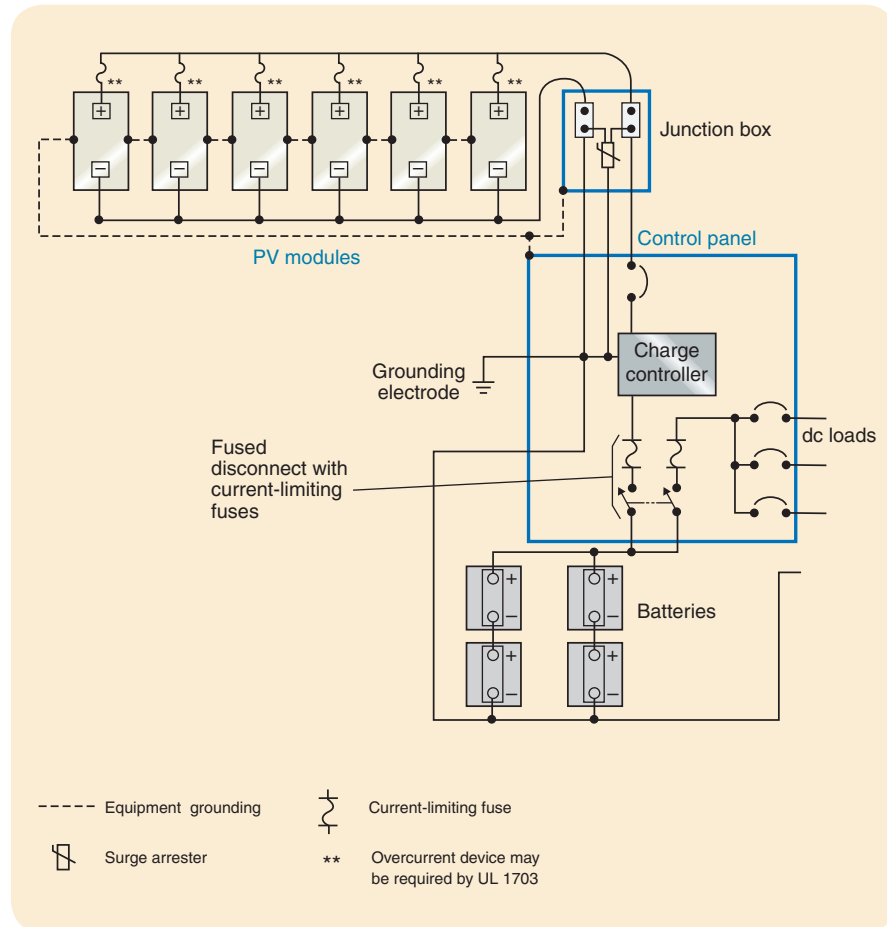

Informational Note: See Article 100 for the definition of *qualified person*.

**(F) Circuit Routing.** Photovoltaic source and PV output conductors, in and out of conduit, and inside of a building or structure, shall be routed along building structural members

such as beams, rafters, trusses, and columns where the location of those structural members can be determined by observation. Where circuits are imbedded in built-up, laminate, or membrane roofing materials in roof areas not covered by PV modules and associated equipment, the location of circuits shall be clearly marked.

The general requirement covering the location of the photovoltaic disconnecting means in 690.14(C)(1) specifies that it be located nearest to the point where the PV circuit conductors enter a building or structure. The distance between the array and the disconnecting means is not limited by the *Code*. The PV circuit conductors between the photovoltaic power source and the PV disconnecting means are energized whenever the source is producing power. Because of this potential exposure to energized conductors, a marking is required to warn roofers, other tradespersons, or first responders of the location of energized PV conductors where PV source or output circuits are “imbedded” or concealed by the roofing material. This requirement does not apply to conductors installed in areas of the

**EXHIBIT 690.5** Simplified circuit schematic of a remote-cabin dc-only system.

roof covered by PV modules or other associated equipment.

**(G) Bipolar Photovoltaic Systems.** Where the sum, without consideration of polarity, of the PV system voltages of the two monopole subarrays exceeds the rating of the conductors and connected equipment, monopole subarrays in a bipolar PV system shall be physically separated, and the electrical output circuits from each monopole subarray shall be installed in separate raceways until connected to the inverter. The disconnecting means and overcurrent protective devices for each monopole subarray output shall be in separate enclosures. All conductors from each separate monopole subarray shall be routed in the same raceway.

*Exception:* Listed switchgear rated for the maximum voltage between circuits and containing a physical barrier separating the disconnecting means for each monopole subarray shall be permitted to be used instead of disconnecting means in separate enclosures.

**(H) Multiple Inverters.** A PV system shall be permitted to have multiple utility-interactive inverters installed in or on a single building or structure. Where the inverters are remotely located from each other, a directory in accordance with 705.10 shall be installed at each dc PV system disconnecting means, at each ac disconnecting means, and at the main service disconnecting means showing the location of all ac and dc PV system disconnecting means in the building.

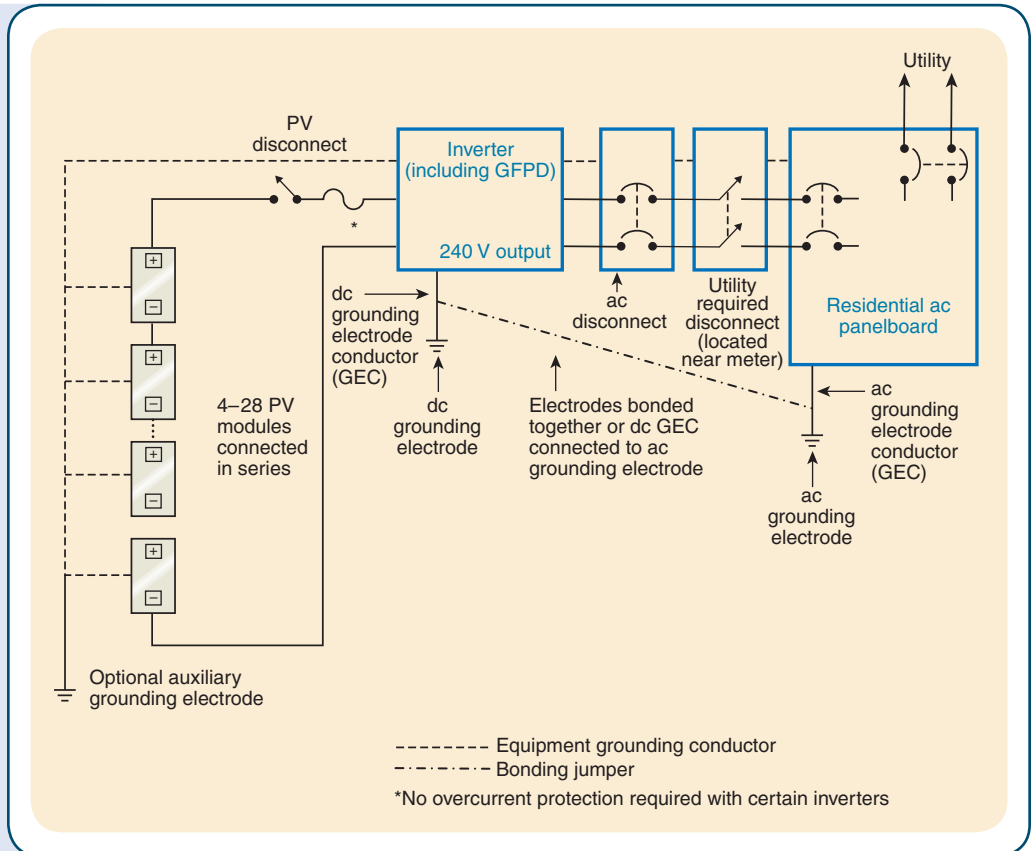

*Exception:* A directory shall not be required where all inverters and PV dc disconnecting means are grouped at the main service disconnecting means.

### 690.5 Ground-Fault Protection

Grounded dc photovoltaic arrays shall be provided with dc ground-fault protection meeting the requirements of 690.5(A) through (C) to reduce fire hazards. Ungrounded dc photovoltaic arrays shall comply with 690.35.

*Exception No. 1:* Ground-mounted or pole-mounted photovoltaic arrays with not more than two paralleled source cir-

**EXHIBIT 690.6** Simplified circuit schematic of a rooftop grid-connected system.

cuits and with all dc source and dc output circuits isolated from buildings shall be permitted without ground-fault protection.

*Exception No. 2:* Photovoltaic arrays installed at other than dwelling units shall be permitted without ground-fault protection if each equipment grounding conductor is sized in accordance with 690.45.

Ground-fault detection and interruption for the direct-current portions of PV systems should not be confused with the requirements for alternating-current circuit GFCI protection, as defined in Article 100. A GFCI is intended for the protection of personnel in single-phase ac systems. The ac GFCI functions to open the ungrounded conductor when a 5-mA fault current is detected. In contrast, devices meeting the requirements of 690.5 are intended to prevent fires in dc PV circuits due to ground faults.

**(A) Ground-Fault Detection and Interruption.** The ground-fault protection device or system shall be capable of detecting a ground-fault current, interrupting the flow of fault current, and providing an indication of the fault.

Automatically opening the grounded conductor of the faulted circuit to interrupt the ground-fault current path shall

be permitted. If a grounded conductor is opened to interrupt the ground-fault current path, all conductors of the faulted circuit shall be automatically and simultaneously opened.

Manual operation of the main PV dc disconnect shall not activate the ground-fault protection device or result in grounded conductors becoming ungrounded.

Typical ground-fault protection devices meeting the requirements of 690.5(A) operate by opening the main dc bonding jumper. They sense dc ground faults anywhere on the dc system and may be mounted anywhere in that system. They are usually installed inside the utility-interactive inverters or in the dc power center in stand-alone PV systems. Ground-fault protection accomplished through the opening of the grounded conductor also has to incorporate disconnecting means to automatically open all conductors of the faulted circuit.

**(B) Isolating Faulted Circuits.** The faulted circuits shall be isolated by one of the two following methods:

- (1) The ungrounded conductors of the faulted circuit shall be automatically disconnected.
- (2) The inverter or charge controller fed by the faulted circuit shall automatically cease to supply power to output circuits.

Typical ground-fault protection devices operating in PV systems (48-volt nominal and below) automatically disconnect the ungrounded conductor with a circuit breaker mechanically linked to a ground-fault-sensing circuit breaker. Equipment operating above 48 volts nominal usually automatically shuts off the connected equipment to meet this requirement when a ground fault is sensed.

**(C) Labels and Markings.** A warning label shall appear on the utility-interactive inverter or be applied by the installer near the ground-fault indicator at a visible location, stating the following:

WARNING  
ELECTRIC SHOCK HAZARD  
IF A GROUND FAULT IS INDICATED,  
NORMALLY GROUNDED CONDUCTORS MAY  
BE UNGROUNDED AND ENERGIZED

When the photovoltaic system also has batteries, the same warning shall also be applied by the installer in a visible location at the batteries.

Many types of ground-fault detection and interruption equipment break the negative-to-ground bond to interrupt the fault currents, and the now ungrounded PV negative conductor generally is at open-circuit voltage below the ground reference (e.g.,  $-400$  volts).

## 690.6 Alternating-Current (ac) Modules

**(A) Photovoltaic Source Circuits.** The requirements of Article 690 pertaining to photovoltaic source circuits shall not apply to ac modules. The photovoltaic source circuit, conductors, and inverters shall be considered as internal wiring of an ac module.

**(B) Inverter Output Circuit.** The output of an ac module shall be considered an inverter output circuit.

**(C) Disconnecting Means.** A single disconnecting means, in accordance with 690.15 and 690.17, shall be permitted for the combined ac output of one or more ac modules. Additionally, each ac module in a multiple ac module system shall be provided with a connector, bolted, or terminal-type disconnecting means.

Alternating-current PV modules, as utility-interactive devices, are designed to produce ac power only when they are connected to an external source of ac power at the correct voltage and frequency. A single disconnecting means re-

moves the external source and turns off all ac PV modules connected to that disconnecting device.

**(D) Ground-Fault Detection.** Alternating-current module systems shall be permitted to use a single detection device to detect only ac ground faults and to disable the array by removing ac power to the ac module(s).

The detection device permitted by 690.6(D) is a fire prevention device and is not intended to be a shock prevention device. Existing GFCI and equipment ground-fault protection devices are generally not listed for backfeeding and are not suitable for meeting this requirement.

**(E) Overcurrent Protection.** The output circuits of ac modules shall be permitted to have overcurrent protection and conductor sizing in accordance with 240.5(B)(2).

## II. Circuit Requirements

### 690.7 Maximum Voltage

**(A) Maximum Photovoltaic System Voltage.** In a dc photovoltaic source circuit or output circuit, the maximum photovoltaic system voltage for that circuit shall be calculated as the sum of the rated open-circuit voltage of the series-connected photovoltaic modules corrected for the lowest expected ambient temperature. For crystalline and multicrystalline silicon modules, the rated open-circuit voltage shall be multiplied by the correction factor provided in Table 690.7. This voltage shall be used to determine the voltage rating of cables, disconnects, overcurrent devices, and other equipment. Where the lowest expected ambient temperature is below  $-40^{\circ}\text{C}$  ( $-40^{\circ}\text{F}$ ), or where other than crystalline or multicrystalline silicon photovoltaic modules are used, the system voltage adjustment shall be made in accordance with the manufacturer's instructions.

When open-circuit voltage temperature coefficients are supplied in the instructions for listed PV modules, they shall be used to calculate the maximum photovoltaic system voltage as required by 110.3(B) instead of using Table 690.7.

**Informational Note:** One source for statistically valid, lowest-expected, ambient temperature design data for various locations is the Extreme Annual Mean Minimum Design Dry Bulb Temperature found in the *ASHRAE Handbook — Fundamentals*. These temperature data can be used to calculate maximum voltage using the manufacturer's temperature coefficients relative to the rating temperature of  $25^{\circ}\text{C}$ .

A PV source is not a constant-voltage source, and the difference between the rated operating voltage determined

under controlled laboratory conditions and the open-circuit voltage under field-installed conditions can be significant. Consequently, the higher-rated open-circuit voltage must be used to select circuit components with proper voltage ratings.

The voltage potential (both open circuit and operating) of a PV power source increases with decreasing temperature. The installer should note the temperature conditions under which the PV device was rated. If the anticipated lowest temperature at the installation site is lower than the rating condition (25°C), Table 690.7 should be used to adjust the maximum open-circuit voltage of the crystalline system before conductors, overcurrent devices, and switchgear are selected.

The temperature adjustment requirement is also included in the instructions provided with listed PV modules and is established at a fixed 125 percent, regardless of temperature. Table 690.7 supersedes the fixed 125 percent where the lowest temperature is above -40°C.

Where a listed PV module includes open-circuit voltage temperature coefficients in the installation instructions, these temperature coefficients provide a more accurate maximum system voltage and are required to be used instead of applying Table 690.7. The *NEC* does not require temperature coefficient information to be included in the installation instructions.

Bipolar PV systems (with positive and negative voltages) must use the sum of the absolute values of the open-circuit voltages to determine the rated open-circuit system voltage. For example, a system with open-circuit voltages of +480 volts and -480 volts with respect to ground would have a system open-circuit voltage of 960 volts. This voltage should be multiplied by a temperature-dependent factor from Table 690.7, yielding a system design voltage of up to 1200 volts. The system design voltage should be used in the selection of cables and other equipment. Also, see the definition of *photovoltaic system voltage* in 690.2. Certain methods of connecting bipolar PV arrays meeting the requirements of 690.7(E) may have different requirements for calculating the maximum system voltage.

**(B) Direct-Current Utilization Circuits.** The voltage of dc utilization circuits shall conform to 210.6.

The requirements of 690.7(B) cover installations where the PV output is connected to dc utilization circuits.

**(C) Photovoltaic Source and Output Circuits.** In one- and two-family dwellings, photovoltaic source circuits and photovoltaic output circuits that do not include lampholders, fixtures, or receptacles shall be permitted to have a

**TABLE 690.7 Voltage Correction Factors for Crystalline and Multicrystalline Silicon Modules**

**Correction Factors for Ambient Temperatures Below 25°C (77°F). (Multiply the rated open circuit voltage by the appropriate correction factor shown below.)**

Ambient Temperature (°C)	Factor	Ambient Temperature (°F)
24 to 20	1.02	76 to 68
19 to 15	1.04	67 to 59
14 to 10	1.06	58 to 50
9 to 5	1.08	49 to 41
4 to 0	1.10	40 to 32
-1 to -5	1.12	31 to 23
-6 to -10	1.14	22 to 14
-11 to -15	1.16	13 to 5
-16 to -20	1.18	4 to -4
-21 to -25	1.20	-5 to -13
-26 to -30	1.21	-14 to -22
-31 to -35	1.23	-23 to -31
-36 to -40	1.25	-32 to -40

maximum photovoltaic system voltage up to 600 volts. Other installations with a maximum photovoltaic system voltage over 600 volts shall comply with Article 690, Part IX.

A significant difference exists between the rated open-circuit voltage and the operating voltage in PV dc circuits. For the PV system to perform its intended function, rated dc open-circuit voltages of up to 600 volts may be present.

**(D) Circuits over 150 Volts to Ground.** In one- and two-family dwellings, live parts in photovoltaic source circuits and photovoltaic output circuits over 150 volts to ground shall not be accessible to other than qualified persons while energized.

Informational Note: See 110.27 for guarding of live parts, and 210.6 for voltage to ground and between conductors.

Where dc circuitry over 150 volts to ground is present in one- and two-family dwellings, additional protection for unqualified persons may be needed. Protection may be in the form of conduit, a closed cabinet, or an enclosure that requires the use of tools to open it and that permits entry only by qualified persons.

**(E) Bipolar Source and Output Circuits.** For 2-wire circuits connected to bipolar systems, the maximum system voltage shall be the highest voltage between the conductors

of the 2-wire circuit if all of the following conditions apply:

- (1) One conductor of each circuit of a bipolar subarray is solidly grounded.

*Exception: The operation of ground-fault or arc-fault devices (abnormal operation) shall be permitted to interrupt this connection to ground when the entire bipolar array becomes two distinct arrays isolated from each other and the utilization equipment.*

- (2) Each circuit is connected to a separate subarray.
- (3) The equipment is clearly marked with a label as follows:

**WARNING**  
**BIPOLAR PHOTOVOLTAIC ARRAY.**  
**DISCONNECTION OF NEUTRAL OR**  
**GROUNDING CONDUCTORS MAY RESULT IN**  
**OVERVOLTAGE ON ARRAY OR INVERTER.**

## 690.8 Circuit Sizing and Current

**(A) Calculation of Maximum Circuit Current.** The maximum current for the specific circuit shall be calculated in accordance with 690.8(A)(1) through (A)(4).

Informational Note: Where the requirements of 690.8(A)(1) and (B)(1) are both applied, the resulting multiplication factor is 156 percent.

**(1) Photovoltaic Source Circuit Currents.** The maximum current shall be the sum of parallel module rated short-circuit currents multiplied by 125 percent.

The use of the array short-circuit current allows for proper sizing of conductors to handle the current generated during extended periods of operation under a short-circuit current operating point.

The 125 percent factor is required by 690.8(A)(1) because PV modules, PV source circuits, and PV output circuits can deliver output currents higher than the rated short-circuit currents for more than 3 hours near solar noon. This requirement is duplicated in the instructions provided with each listed module, but this factor only needs to be applied once. A second 125 percent factor is required by 690.8(B).

PV modules in hot climates operate at temperatures of 60°C to 80°C due to solar heating. Conductors with insulation types rated at least 90°C should be used, and these conductors should have the ampacity corrected in accordance with Table 310.15(B)(16) or Table 310.15(B)(17).

**(2) Photovoltaic Output Circuit Currents.** The maximum current shall be the sum of parallel source circuit maximum currents as calculated in 690.8(A)(1).

**(3) Inverter Output Circuit Current.** The maximum current shall be the inverter continuous output current rating.

Both stand-alone and utility-interactive inverters are power-limited devices. Output circuits connected to these devices are sized on the continuous rated outputs of these devices and are not based on load calculations or reduced-size PV arrays or battery banks, if any. Some inverters may have specifications listing sustained maximum output currents, and the higher of this number or the rated output should be used.

**(4) Stand-Alone Inverter Input Circuit Current.** The maximum current shall be the stand-alone continuous inverter input current rating when the inverter is producing rated power at the lowest input voltage.

Stand-alone inverters are nearly constant-output voltage devices. As the input battery voltage decreases, the input battery current increases to maintain a constant ac output power. The input current for such inverters is calculated by taking the rated full-power output of the inverter in watts and dividing it by the lowest operating battery voltage and then by the rated efficiency of the inverter under those operating conditions.

For example, the input current for a 4000-watt, 24-volt inverter that is 85 percent efficient at 22 volts can be calculated as follows:

$$\begin{aligned}\text{Ampere input} &= \frac{\text{watt output}}{\text{voltage} \times \text{efficiency}} \\ &= \frac{4000 \text{ W}}{22 \text{ V} \times 0.85} \\ &= 214 \text{ A}\end{aligned}$$

Ripple currents might be present in the dc-input circuits of single-phase, stand-alone inverters. These ripple currents might cause nuisance operation of overcurrent devices at continuous high inverter outputs. In such cases, the measured maximum true rms (root mean square) value of the total (ac + dc) input current, which will be greater than the average current calculated here, should be used to determine conductor sizes and overcurrent device ratings.

**(B) Ampacity and Overcurrent Device Ratings.** Photovoltaic system currents shall be considered to be continuous.

**(1) Overcurrent Devices.** Overcurrent devices, where required, shall be rated as required by 690.8(B)(1)(a) through (1)(d).

(a) To carry not less than 125 percent of the maximum currents calculated in 690.8(A).

*Exception: Circuits containing an assembly, together with its overcurrent device(s), that is listed for continuous operation at 100 percent of its rating shall be permitted to be used at 100 percent of its rating.*

The exception to 690.8(B)(1)(a) permits use at the full rating of assemblies, such as panelboards, incorporating overcurrent devices listed for continuous operation at 100 percent of the rating.

(b) Terminal temperature limits shall be in accordance with 110.3(B) and 110.14(C).

(c) Where operated at temperatures greater than 40°C (104°F), the manufacturer's temperature correction factors shall apply.

(d) The rating or setting of overcurrent devices shall be permitted in accordance with 240.4(B), (C), and (D).

(2) **Conductor Ampacity.** Circuit conductors shall be sized to carry not less than the larger of 690.8(B)(2)(a) or (2)(b).

(a) One hundred and twenty-five percent of the maximum currents calculated in 690.8(A) without any additional correction factors for conditions of use.

(b) The maximum currents calculated in 690.8(A) after conditions of use have been applied.

(c) The conductor selected, after application of conditions of use, shall be protected by the overcurrent protective device, where required.

(C) **Systems with Multiple Direct-Current Voltages.** For a photovoltaic power source that has multiple output circuit voltages and employs a common-return conductor, the ampacity of the common-return conductor shall not be less than the sum of the ampere ratings of the overcurrent devices of the individual output circuits.

(D) **Sizing of Module Interconnection Conductors.** Where a single overcurrent device is used to protect a set of two or more parallel-connected module circuits, the ampacity of each of the module interconnection conductors shall not be less than the sum of the rating of the single fuse plus 125 percent of the short-circuit current from the other parallel-connected modules.

Normally, labeling or module instructions require reverse overcurrent protection for each module or string of modules. In some cases, modules with low-rated short-circuit currents and high values of the required series protective fuse may allow the use of one overcurrent device to provide reverse-

current protection for two modules or strings of modules and overcurrent protection for the conductors. The PV module manufacturer should be contacted for specific information.

## 690.9 Overcurrent Protection

(A) **Circuits and Equipment.** Photovoltaic source circuit, photovoltaic output circuit, inverter output circuit, and storage battery circuit conductors and equipment shall be protected in accordance with the requirements of Article 240. Circuits connected to more than one electrical source shall have overcurrent devices located so as to provide overcurrent protection from all sources.

*Exception: An overcurrent device shall not be required for PV modules or PV source circuit conductors sized in accordance with 690.8(B) where one of the following applies:*

- (a) *There are no external sources such as parallel-connected source circuits, batteries, or backfeed from inverters.*
- (b) *The short-circuit currents from all sources do not exceed the ampacity of the conductors or the maximum overcurrent protective device size specified on the PV module nameplate.*

**Informational Note:** Possible backfeed of current from any source of supply, including a supply through an inverter into the photovoltaic output circuit and photovoltaic source circuits, is a consideration in determining whether adequate overcurrent protection from all sources is provided for conductors and modules.

In the circuits illustrated in Exhibits 690.3, 690.4, 690.5, and 690.6, the PV source-circuit overcurrent devices are required to be rated so that the source-circuit conductors are protected in accordance with Article 240 and so that the overcurrent device ratings do not exceed the maximum overcurrent device rating marked on the modules. Possible backfeed currents from the other PV source circuits, other supply sources through the inverter, and storage-battery circuits, if any, have to be considered.

Blocking diodes (possibly required by the module manufacturer for specific applications) can lose their blocking ability because of overtemperature conditions or internal breakdown. Therefore, overcurrent protection has to be considered with a condition of shorted blocking diodes if they are used in the circuit.

In typical one- and two-family dwelling unit utility-interactive PV systems, overcurrent devices may only be required in the dc PV source or output circuits where there are more than two strings of PC modules connected in parallel.

At the inverter or battery/charge controller end of the PV output circuit, the need for overcurrent protection has to

be considered with respect to the maximum backfeed fault current available from other sources.

**(B) Power Transformers.** Overcurrent protection for a transformer with a source(s) on each side shall be provided in accordance with 450.3 by considering first one side of the transformer, then the other side of the transformer, as the primary.

*Exception: A power transformer with a current rating on the side connected toward the utility-interactive inverter output, not less than the rated continuous output current of the inverter, shall be permitted without overcurrent protection from the inverter.*

**(C) Photovoltaic Source Circuits.** Branch-circuit or supplementary-type overcurrent devices shall be permitted to provide overcurrent protection in photovoltaic source circuits. The overcurrent devices shall be accessible but shall not be required to be readily accessible.

Standard values of supplementary overcurrent devices allowed by this section shall be in one ampere size increments, starting at one ampere up to and including 15 amperes. Higher standard values above 15 amperes for supplementary overcurrent devices shall be based on the standard sizes provided in 240.6(A).

If the overcurrent protection of PV source circuits is considered supplementary overcurrent protection, use of overcurrent devices with ratings other than those suitable for branch-circuit protection is permitted. The use of such devices permits module protection closer to the specified ratings required on the labels attached to listed modules. It is anticipated that only qualified service personnel will replace or reset overcurrent devices in PV source circuits. Consequently, ready access to the user need not be provided. These supplementary overcurrent devices must be listed for dc operation and have appropriate voltage and current ratings.

Overcurrent devices used to protect modules or module interconnections may be installed in enclosures mounted outdoors in locations exposed to direct sunlight that may subject the overcurrent devices to operating temperatures higher than 40°C. Appropriate derating instructions are available from the overcurrent device manufacturer.

**(D) Direct-Current Rating.** Overcurrent devices, either fuses or circuit breakers, used in any dc portion of a photovoltaic power system shall be listed for use in dc circuits and shall have the appropriate voltage, current, and interrupt ratings.

Direct-current fault currents are considerably harder to interrupt than ac faults. Overcurrent devices marked or listed only for ac use should not be used in dc circuits. Automotive- and marine-type fuses, although used in these dc systems, are not suitable for use in permanently wired residential or commercial electrical power systems meeting the requirements of the *Code*.

**(E) Series Overcurrent Protection.** In PV source circuits, a single overcurrent protection device shall be permitted to protect the PV modules and the interconnecting conductors.

The single overcurrent device (when required) may provide both the reverse-current protection required for the series-connected PV modules and the overcurrent protection required for the interconnecting conductors.

## 690.10 Stand-Alone Systems

The premises wiring system shall be adequate to meet the requirements of this *Code* for a similar installation connected to a service. The wiring on the supply side of the building or structure disconnecting means shall comply with this *Code* except as modified by 690.10(A) through (E).

**(A) Inverter Output.** The ac output from a stand-alone inverter(s) shall be permitted to supply ac power to the building or structure disconnecting means at current levels less than the calculated load connected to that disconnect. The inverter output rating or the rating of an alternate energy source shall be equal to or greater than the load posed by the largest single utilization equipment connected to the system. Calculated general lighting loads shall not be considered as a single load.

A stand-alone residential or commercial PV installation may have an ac output and be connected to a building wired in full compliance with all articles of this *Code*. Even though such an installation may have service-entrance equipment rated at 100 or 200 amperes at 120/240 volts, the PV source is not required to provide either the full current rating or the dual voltages of the service equipment. While safety requirements dictate full compliance with the ac wiring sections of the *Code*, a PV installation is usually designed so that the actual ac demands on the system are sized to the output rating of the PV system. The inverter output is required by 690.10(A) to have sufficient capacity to power the largest single piece of utilization equipment to be supplied by the PV system, but the inverter output does not have to be sized for the potential multiple loads to be simultaneously

connected to it. Lighting loads are managed by the user based on the available energy from the PV system.

**(B) Sizing and Protection.** The circuit conductors between the inverter output and the building or structure disconnecting means shall be sized based on the output rating of the inverter. These conductors shall be protected from overcurrents in accordance with Article 240. The overcurrent protection shall be located at the output of the inverter.

**(C) Single 120-Volt Supply.** The inverter output of a stand-alone solar photovoltaic system shall be permitted to supply 120 volts to single-phase, 3-wire, 120/240-volt service equipment or distribution panels where there are no 240-volt outlets and where there are no multiwire branch circuits. In all installations, the rating of the overcurrent device connected to the output of the inverter shall be less than the rating of the neutral bus in the service equipment. This equipment shall be marked with the following words or equivalent:

**WARNING**  
SINGLE 120-VOLT SUPPLY. DO NOT CONNECT  
MULTIWIRE BRANCH CIRCUITS!

Multiwire branch circuits are common in one- and two-family dwelling units. When connected to a normal 120/240-volt ac service, the currents in the neutral conductors of these multiwire branch circuits (typically 14-3 AWG) subtract or are, at most, no larger than the rating of the branch-circuit overcurrent device. When these electrical systems are connected to a single 120-volt PV power system inverter by paralleling the two ungrounded conductors in the service-entrance load center, the currents in the neutral conductor for each multiwire branch circuit add rather than subtract. The currents in the neutral conductor may be as high as twice the rating of the branch-circuit overcurrent device. With this configuration, neutral conductor overloading is possible.

**(D) Energy Storage or Backup Power System Requirements.** Energy storage or backup power supplies are not required.

Stand-alone PV systems may be operated without energy storage or backup power. The systems are tailored to meet the load requirements.

**(E) Back-fed Circuit Breakers.** Plug-in type back-fed circuit breakers connected to a stand-alone inverter output in either stand-alone or utility-interactive systems shall be se-

cured in accordance with 408.36(D). Circuit breakers that are marked “line” and “load” shall not be backfed.

### 690.11 Arc-Fault Circuit Protection (Direct Current)

Photovoltaic systems with dc source circuits, dc output circuits, or both, on or penetrating a building operating at a PV system maximum system voltage of 80 volts or greater, shall be protected by a listed (dc) arc-fault circuit interrupter, PV type, or other system components listed to provide equivalent protection. The PV arc-fault protection means shall comply with the following requirements:

- (1) The system shall detect and interrupt arcing faults resulting from a failure in the intended continuity of a conductor, connection, module, or other system component in the dc PV source and output circuits.
- (2) The system shall disable or disconnect one of the following:
  - a. Inverters or charge controllers connected to the fault circuit when the fault is detected
  - b. System components within the arcing circuit
- (3) The system shall require that the disabled or disconnected equipment be manually restarted.
- (4) The system shall have an annunciator that provides a visual indication that the circuit interrupter has operated. This indication shall not reset automatically.

To mitigate fire initiation hazards associated with arcing type faults occurring in dc source circuits and dc output circuits, 690.11 requires arc-fault circuit protection for PV systems. The requirement applies only where the conductors are installed on or in a building. The arc-fault protection device used to meet this requirement must be listed for dc and for use in photovoltaic systems. Listed components that provide protection equivalent to arc-fault protection are also permitted by this requirement.

## III. Disconnecting Means

### 690.13 All Conductors

Means shall be provided to disconnect all current-carrying dc conductors of a photovoltaic system from all other conductors in a building or other structure. A switch, circuit breaker, or other device shall not be installed in a grounded conductor if operation of that switch, circuit breaker, or other device leaves the marked, grounded conductor in an ungrounded and energized state.

*Exception No. 1: A switch or circuit breaker that is part of a ground-fault detection system required by 690.5, or that is*

part of an arc-fault detection/interruption system required by 690.11, shall be permitted to open the grounded conductor when that switch or circuit breaker is automatically opened as a normal function of the device in responding to ground faults.

**Exception No. 2:** A disconnecting switch shall be permitted in a grounded conductor if all of the following conditions are met:

- (1) The switch is used only for PV array maintenance.
- (2) The switch is accessible only by qualified persons.
- (3) The switch is rated for the maximum dc voltage and current that could be present during any operation, including ground-fault conditions.

**Informational Note:** The grounded conductor may have a bolted or terminal disconnecting means to allow maintenance or troubleshooting by qualified personnel.

### 690.14 Additional Provisions

Photovoltaic disconnecting means shall comply with 690.14(A) through (D).

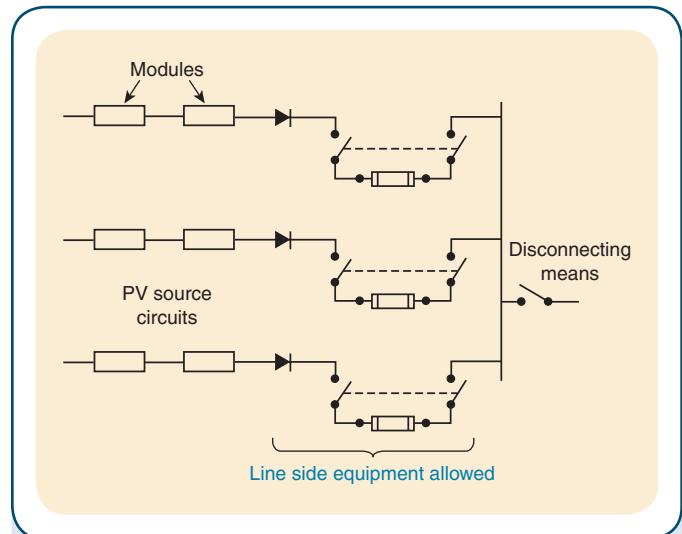

**(A) Disconnecting Means.** The disconnecting means shall not be required to be suitable as service equipment and shall comply with 690.17.

**(B) Equipment.** Equipment such as photovoltaic source circuit isolating switches, overcurrent devices, and blocking diodes shall be permitted on the photovoltaic side of the photovoltaic disconnecting means.

In general, equipment that needs servicing must be disconnected from sources of supply. In a PV system, however, some equipment, as indicated, is permitted to be located on the PV power source side of the disconnecting means. See Exhibit 690.7. Servicing the exempted equipment might require disabling all or portions of the array, as explained in the commentary following 690.18.

A disconnecting means located in each PV source circuit or located physically at each PV module location is not required. Unlike load circuits (e.g., rooftop air conditioners), PV source-circuit conductors may be energized at any time from the PV modules. A centrally located disconnect meeting the requirements of 690.14(C)(1) near the inverter or batteries serves to disconnect the PV source circuits from the other portions of the electric power system.

**(C) Requirements for Disconnecting Means.** Means shall be provided to disconnect all conductors in a building or other structure from the photovoltaic system conductors.

**EXHIBIT 690.7** Equipment permitted on the PV power source side of the PV power source disconnecting means.

**(1) Location.** The photovoltaic disconnecting means shall be installed at a readily accessible location either on the outside of a building or structure or inside nearest the point of entrance of the system conductors.

*Exception:* Installations that comply with 690.31(E) shall be permitted to have the disconnecting means located remote from the point of entry of the system conductors.

The photovoltaic system disconnecting means shall not be installed in bathrooms.

These requirements generally prohibit long runs of PV source and output circuits inside a building before reaching the required PV disconnect. A short conductor run through a wall at the point of first penetration to reach a disconnect mounted inside the building is allowed. Section 690.31(E) permits these circuits to be run inside a building when installed in metal conduit from the point of entrance to the system disconnecting means.

**(2) Marking.** Each photovoltaic system disconnecting means shall be permanently marked to identify it as a photovoltaic system disconnect.

**(3) Suitable for Use.** Each photovoltaic system disconnecting means shall be suitable for the prevailing conditions. Equipment installed in hazardous (classified) locations shall comply with the requirements of Articles 500 through 517.

**(4) Maximum Number of Disconnects.** The photovoltaic system disconnecting means shall consist of not more than six

switches or six circuit breakers mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard.

**(5) Grouping.** The photovoltaic system disconnecting means shall be grouped with other disconnecting means for the system to comply with 690.14(C)(4). A photovoltaic disconnecting means shall not be required at the photovoltaic module or array location.

Where a building has multiples sources of power, such as the utility, the PV array, backup generator, and wind system, no more than six disconnects for each source of power to the building, are allowed, and the disconnects for each source are required to be grouped together. However, a PV system may be considered a source of supply separate from a utility source under certain conditions (see 230.2), and each source may have up to six grouped disconnecting means as permitted by 230.72.

**(D) Utility-Interactive Inverters Mounted in Not-Readily-Accessible Locations.** Utility-interactive inverters shall be permitted to be mounted on roofs or other exterior areas that are not readily accessible. These installations shall comply with (1) through (4):

- (1) A direct-current photovoltaic disconnecting means shall be mounted within sight of or in the inverter.
- (2) An alternating-current disconnecting means shall be mounted within sight of or in the inverter.

This section permits the utility-interactive inverter to be installed in a location that is not readily accessible, so the requirements in 690.14(D)(1) and (D)(2) provide for dc and ac disconnecting means at the inverter location to facilitate servicing of the inverter.

- (3) The alternating-current output conductors from the inverter and an additional alternating-current disconnecting means for the inverter shall comply with 690.14(C)(1).

The disconnect required by 690.14(C)(1) allows the inverter(s) and the circuit to it (them) to be de-energized from a readily accessible location.

- (4) A plaque shall be installed in accordance with 705.10.

### 690.15 Disconnection of Photovoltaic Equipment

Means shall be provided to disconnect equipment, such as inverters, batteries, charge controllers, and the like, from all

ungrounded conductors of all sources. If the equipment is energized from more than one source, the disconnecting means shall be grouped and identified.

A single disconnecting means in accordance with 690.17 shall be permitted for the combined ac output of one or more inverters or ac modules in an interactive system.

### 690.16 Fuses

Switches, pullouts, or similar devices that have suitable ratings may serve as means to disconnect fuses from all sources of supply.

**(A) Disconnecting Means.** Disconnecting means shall be provided to disconnect a fuse from all sources of supply if the fuse is energized from both directions. Such a fuse in a photovoltaic source circuit shall be capable of being disconnected independently of fuses in other photovoltaic source circuits.

**(B) Fuse Servicing.** Disconnecting means shall be installed on PV output circuits where overcurrent devices (fuses) must be serviced that cannot be isolated from energized circuits. The disconnecting means shall be within sight of, and accessible to, the location of the fuse or integral with fuse holder and shall comply with 690.17. Where the disconnecting means are located more than 1.8 m (6 ft) from the overcurrent device, a directory showing the location of each disconnect shall be installed at the overcurrent device location.

Non-load-break-rated disconnecting means shall be marked "Do not open under load."

### 690.17 Switch or Circuit Breaker

The disconnecting means for ungrounded conductors shall consist of a manually operable switch(es) or circuit breaker(s) complying with all of the following requirements:

- (1) Located where readily accessible
- (2) Externally operable without exposing the operator to contact with live parts
- (3) Plainly indicating whether in the open or closed position
- (4) Having an interrupting rating sufficient for the nominal circuit voltage and the current that is available at the line terminals of the equipment

Where all terminals of the disconnecting means may be energized in the open position, a warning sign shall be mounted on or adjacent to the disconnecting means. The sign shall be clearly legible and have the following words or equivalent:

**WARNING**  
**ELECTRIC SHOCK HAZARD.**  
**DO NOT TOUCH TERMINALS. TERMINALS**  
**ON BOTH THE LINE AND LOAD SIDES**  
**MAY BE ENERGIZED IN THE OPEN POSITION.**

*Exception: A connector shall be permitted to be used as an ac or a dc disconnecting means, provided that it complies with the requirements of 690.33 and is listed and identified for the use.*

### 690.18 Installation and Service of an Array

Open circuiting, short circuiting, or opaque covering shall be used to disable an array or portions of an array for installation and service.

**Informational Note:** Photovoltaic modules are energized while exposed to light. Installation, replacement, or servicing of array components while a module(s) is irradiated may expose persons to electric shock.

To prevent contact with energized parts by personnel during installation, servicing, or other procedures, a number of methods can be used to disable an array or portions of an array. One method, used infrequently because of the expense in time and materials, is to cover all of the array or portions of it with an opaque material. Care must be taken that all of the area to be covered is shielded from light. Another method divides the array into nonhazardous segments, which can be accomplished by switches or connectors. Also see 690.33. Short-circuiting all or portions of an array by means of switches or plug-in connectors, in conjunction with the bypass diodes internal to each module, can also provide the necessary disablement. (Bypass diodes are incorporated in PV modules for performance purposes.)

## IV. Wiring Methods

### 690.31 Methods Permitted

**(A) Wiring Systems.** All raceway and cable wiring methods included in this *Code* and other wiring systems and fittings specifically intended and identified for use on photovoltaic arrays shall be permitted. Where wiring devices with integral enclosures are used, sufficient length of cable shall be provided to facilitate replacement.

Where photovoltaic source and output circuits operating at maximum system voltages greater than 30 volts are installed in readily accessible locations, circuit conductors shall be installed in a raceway.

Most PV modules do not have provisions for attaching raceways. These circuits may have to be made “not readily accessible” by use of physical barriers such as wire screening.

**Informational Note:** Photovoltaic modules operate at elevated temperatures when exposed to high ambient temperatures and to bright sunlight. These temperatures may routinely exceed 70°C (158°F) in many locations. Module interconnection conductors are available with insulation rated for wet locations and a temperature rating of 90°C (194°F) or greater.

**(B) Single-Conductor Cable.** Single-conductor cable type USE-2, and single-conductor cable listed and labeled as photovoltaic (PV) wire shall be permitted in exposed outdoor locations in photovoltaic source circuits for photovoltaic module interconnections within the photovoltaic array.

*Exception: Raceways shall be used when required by 690.31(A).*

**Informational Note:** Photovoltaic (PV) wire [also photovoltaic (PV) cable] has a nonstandard outer diameter. Conduit fill may be calculated using Table 1 of Chapter 9.

Most PV modules are designed for a direct series connection by using factory-installed leads and connectors. To accommodate such a direct series connection without the waste of one or more conductors in a multiconductor cable, use of a single-conductor Type USE-2 cable and single-conductor cable listed and labeled for PV applications is permitted in PV source circuits. Long runs of separated conductors (with loop inductance and distributed capacitance) and the resulting long time constants in dc circuits may result in improper operation of overcurrent devices. It is suggested that, wherever possible, both positive and negative conductors of each circuit and the equipment grounding conductor be routed as close together as possible to minimize the circuit time constant. The smaller loop resulting from the close routing also decreases induced currents from nearby lightning strikes. Because PV modules may operate at high temperatures and are installed in outdoor, exposed locations, the use of high-temperature, wet-rated conductors such as USE-2, THWN-2, or RHW-2 is advisable. See 310.15(B)(3)(c) for requirements on the ampacities of conductors in circular raceways installed on rooftops exposed to sunlight. Single-conductor cables listed and labeled for use in PV applications will be identified as “PV Wire,” “PV Cable,” “Photovoltaic Wire,” or “Photovoltaic Cable.”

**(C) Flexible Cords and Cables.** Flexible cords and cables, where used to connect the moving parts of tracking PV modules, shall comply with Article 400 and shall be of a type identified as a hard service cord or portable power cable; they shall be suitable for extra-hard usage, listed for outdoor use, water resistant, and sunlight resistant. Allowable ampacities shall be in accordance with 400.5. For ambient temperatures exceeding 30°C (86°F), the ampacities shall be derated by the appropriate factors given in Table 690.31(C).

TABLE 690.31(C) Correction Factors

Ambient Temperature (°C)	Temperature Rating of Conductor				Ambient Temperature (°F)
	60°C (140°F)	75°C (167°F)	90°C (194°F)	105°C (221°F)	
30	1.00	1.00	1.00	1.00	86
31–35	0.91	0.94	0.96	0.97	87–95
36–40	0.82	0.88	0.91	0.93	96–104
41–45	0.71	0.82	0.87	0.89	105–113
46–50	0.58	0.75	0.82	0.86	114–122
51–55	0.41	0.67	0.76	0.82	123–131
56–60	—	0.58	0.71	0.77	132–140
61–70	—	0.33	0.58	0.68	141–158
71–80	—	—	0.41	0.58	159–176

**(D) Small-Conductor Cables.** Single-conductor cables listed for outdoor use that are sunlight resistant and moisture resistant in sizes 16 AWG and 18 AWG shall be permitted for module interconnections where such cables meet the ampacity requirements of 690.8. Section 310.15 shall be used to determine the cable ampacity adjustment and correction factors.

Because the smaller cables permitted by 690.31(D) are not normally marked with standard *Code*-recognized markings (e.g., USE-2), the PV module manufacturer or installer should verify that these cables are listed and labeled for PV use, thereby indicating that they have the necessary sunlight and moisture resistance and are suitable for exposed, outdoor use.

In accordance with 200.6(A), grounded conductors that are smaller than 6 AWG and used in PV source circuits are permitted to be marked at the time of installation with a white marking at all terminations.

**(E) Direct-Current Photovoltaic Source and Output Circuits Inside a Building.** Where dc photovoltaic source or output circuits from a building-integrated or other photovoltaic system are run inside a building or structure, they shall be contained in metal raceways, Type MC metal-clad cable that complies with 250.118(10), or metal enclosures from the point of penetration of the surface of the building or structure to the first readily accessible disconnecting means. The disconnecting means shall comply with 690.14(A), (B), and (D). The wiring methods shall comply with the additional installation requirements in (1) through (4)

The use of metallic raceways, Type MC metal-clad cable, or metal enclosures inside a building provides additional physical protection for these circuits. Metallic raceways also pro-

vide additional fire resistance should faults develop in the cable, and they provide an additional ground-fault detection path for the ground-fault protection device required by 690.5.

**(1) Beneath Roofs.** Wiring methods shall not be installed within 25 cm (10 in.) of the roof decking or sheathing except where directly below the roof surface covered by PV modules and associated equipment. Circuits shall be run perpendicular to the roof penetration point to supports a minimum of 25 cm (10 in.) below the roof decking.

Informational Note: The 25 cm (10 in.) requirement is to prevent accidental damage from saws used by fire fighters for roof ventilation during a structure fire.

**(2) Flexible Wiring Methods.** Where flexible metal conduit (FMC) smaller than metric designator 21 (trade size ¾) or Type MC cable smaller than 25 mm (1 in.) in diameter containing PV power circuit conductors is installed across ceilings or floor joists, the raceway or cable shall be protected by substantial guard strips that are at least as high as the raceway or cable. Where run exposed, other than within 1.8 m (6 ft) of their connection to equipment, these wiring methods shall closely follow the building surface or be protected from physical damage by an approved means.

**(3) Marking or Labeling Required.** The following wiring methods and enclosures that contain PV power source conductors shall be marked with the wording “Photovoltaic Power Source” by means of permanently affixed labels or other approved permanent marking:

- (1) Exposed raceways, cable trays, and other wiring methods
- (2) Covers or enclosures of pull boxes and junction boxes
- (3) Conduit bodies in which any of the available conduit openings are unused

**(4) Marking and Labeling Methods and Locations.** The labels or markings shall be visible after installation. Photovoltaic power circuit labels shall appear on every section of the wiring system that is separated by enclosures, walls, partitions, ceilings, or floors. Spacing between labels or markings, or between a label and a marking, shall not be more than 3 m (10 ft). Labels required by this section shall be suitable for the environment where they are installed.

The objective of the requirements contained in 690.31(E)(1) through (4) is to protect persons from inadvertently damaging PV source and output circuit conductors. Where the location of the PV circuit conductors is not obvious, fire fighters, other first responders, and maintenance personnel could be exposed to shock hazards. Ventilating roofs containing PV source or output circuits by cutting the membrane with saws exposes personnel to shock hazards and the building to further damage resulting from the ignition of combustible members due to arcing from damaged conductors.

**(F) Flexible, Fine-Stranded Cables.** Flexible, fine-stranded cables shall be terminated only with terminals, lugs, devices, or connectors in accordance with 110.14(A).

Flexible, fine-stranded cables recognized in Table 310.104(A) have numerous, very fine strands and can be used only with specially tested, listed, and identified terminations. The terminals, connectors, and crimp-on lugs found on most electrical equipment used in PV systems are *not* suitable for use with these types of cables. The requirements for these fine-stranded conductors are covered in 110.14.

## 690.32 Component Interconnections

Fittings and connectors that are intended to be concealed at the time of on-site assembly, where listed for such use, shall be permitted for on-site interconnection of modules or other array components. Such fittings and connectors shall be equal to the wiring method employed in insulation, temperature rise, and fault-current withstand, and shall be capable of resisting the effects of the environment in which they are used.

### 690.33 Connectors

The connectors permitted by Article 690 shall comply with 690.33(A) through (E).

**(A) Configuration.** The connectors shall be polarized and shall have a configuration that is noninterchangeable with receptacles in other electrical systems on the premises.

**(B) Guarding.** The connectors shall be constructed and installed so as to guard against inadvertent contact with live parts by persons.

**(C) Type.** The connectors shall be of the latching or locking type. Connectors that are readily accessible and that are used in circuits operating at over 30 volts, nominal, maximum system voltage for dc circuits, or 30 volts for ac circuits, shall require a tool for opening.

**(D) Grounding Member.** The grounding member shall be the first to make and the last to break contact with the mating connector.

**(E) Interruption of Circuit.** Connectors shall be either (1) or (2):

- (1) Be rated for interrupting current without hazard to the operator.
- (2) Be a type that requires the use of a tool to open and marked “Do Not Disconnect Under Load” or “Not for Current Interrupting.”

The two options provided for connectors in this requirement provide for safe disconnection of circuit connectors either by being able to be opened under load or by having a warning indicating that disconnection prior to opening the connector is necessary. Connectors that can be opened or disconnected using only the hands are not acceptable.

## 690.34 Access to Boxes

Junction, pull, and outlet boxes located behind modules or panels shall be so installed that the wiring contained in them can be rendered accessible directly or by displacement of a module(s) or panel(s) secured by removable fasteners and connected by a flexible wiring system.

## 690.35 Ungrounded Photovoltaic Power Systems

Photovoltaic power systems shall be permitted to operate with ungrounded photovoltaic source and output circuits where the system complies with 690.35(A) through (G).

**(A) Disconnects.** All photovoltaic source and output circuit conductors shall have disconnects complying with 690, Part III.

**(B) Overcurrent Protection.** All photovoltaic source and output circuit conductors shall have overcurrent protection complying with 690.9.

**(C) Ground-Fault Protection.** All photovoltaic source and output circuits shall be provided with a ground-

fault protection device or system that complies with (1) through (3):

- (1) Detects a ground fault.
- (2) Indicates that a ground fault has occurred
- (3) Automatically disconnects all conductors or causes the inverter or charge controller connected to the faulted circuit to automatically cease supplying power to output circuits.

**(D)** The photovoltaic source conductors shall consist of the following:

- (1) Nonmetallic jacketed multiconductor cables
- (2) Conductors installed in raceways, or
- (3) Conductors listed and identified as Photovoltaic (PV) Wire installed as exposed, single conductors.

Three options for PV source output circuits are provided by 690.35(D). All cables and conductors installed outdoors and exposed to direct sunlight and wet conditions have to be suitable for these conditions, and such suitability is verified by the cables and conductors being listed. Conductors inside raceways installed in wet locations are required to be identified or listed as suitable for this environmental condition. See 310.10(C) for the requirements on conductors installed in wet locations. Open, single conductors are permitted where listed and identified as “Photovoltaic Wire,” “Photovoltaic Cable,” “PV Wire,” or “PV Cable.” These conductors are evaluated for use where exposed to direct sunlight and wet conditions. Although not required as a general rule, these conductors can be installed in a raceway at the discretion of the installer.

**(E)** The photovoltaic power system direct-current circuits shall be permitted to be used with ungrounded battery systems complying with 690.71(G).

**(F)** The photovoltaic power source shall be labeled with the following warning at each junction box, combiner box, disconnect, and device where energized, ungrounded circuits may be exposed during service:

**WARNING**

**ELECTRIC SHOCK HAZARD. THE DC CONDUCTORS  
OF THIS PHOTOVOLTAIC SYSTEM ARE  
UNGROUNDING AND MAY BE ENERGIZED.**

PV dc circuits operate in outdoor environments and are expected to be energized for many years. Aging of the conductors, dust and dirt infiltration, and moisture and water intrusion create leakage paths from the conductors to ground. These high-resistance leakage paths can result in

leakage current values less than those detected by the required ground-fault detection device, but they can cause any ungrounded conductor to become a potential shock hazard with respect to ground.

**(G)** The inverters or charge controllers used in systems with ungrounded photovoltaic source and output circuits shall be listed for the purpose.

Many types of PV equipment are designed to operate only on grounded systems. Equipment to be used on ungrounded systems must be tested and evaluated for such use.

## V. Grounding

### 690.41 System Grounding

For a photovoltaic power source, one conductor of a 2-wire system with a photovoltaic system voltage over 50 volts and the reference (center tap) conductor of a bipolar system shall be solidly grounded or shall use other methods that accomplish equivalent system protection in accordance with 250.4(A) and that utilize equipment listed and identified for the use.

*Exception: Systems complying with 690.35.*

Low-voltage systems that are not grounded are required by 690.41 to be solidly grounded, having overcurrent protection in each of the ungrounded conductors, as required by 240.21. Other methods that employ available equipment may be used to achieve objectives contained in 250.4(A), thereby providing protection for the PV power source circuits equivalent to solid grounding.

### 690.42 Point of System Grounding Connection

The dc circuit grounding connection shall be made at any single point on the photovoltaic output circuit.

**Informational Note:** Locating the grounding connection point as close as practicable to the photovoltaic source better protects the system from voltage surges due to lightning.

*Exception: Systems with a 690.5 ground-fault protection device shall be permitted to have the required grounded conductor-to-ground bond made by the ground-fault protection device. This bond, where internal to the ground-fault equipment, shall not be duplicated with an external connection.*

If other than solid grounding is utilized, as permitted by 690.41, the connections should be made in accordance with

the markings found on the equipment or in the installation instructions.

Stand-alone PV systems might require the grounding connection point to be located close to the high-current conductors associated with the battery and the inverter.

PV systems requiring ground-fault protection devices (see 690.5) are permitted to have the single-point grounding connection made inside the ground-fault protection equipment or inside the utility-interactive inverter and additional external bonding connections are not permitted. Connections are to be made in accordance with markings on the equipment or in the installation instructions.

### 690.43 Equipment Grounding

Equipment grounding conductors and devices shall comply with 690.43(A) through (F).

**(A) Equipment Grounding Required.** Exposed non-current-carrying metal parts of PV module frames, electrical equipment, and conductor enclosures shall be grounded in accordance with 250.134 or 250.136(A), regardless of voltage.

Equipment grounding is required even in low-voltage (12- and 24-volt) systems not otherwise required to have a system ground. A grounding electrode must be added to an ungrounded system to accommodate the equipment grounds.

**(B) Equipment Grounding Conductor Required.** An equipment grounding conductor between a PV array and other equipment shall be required in accordance with 250.110.

**(C) Structure as Equipment Grounding Conductor.** Devices listed and identified for grounding the metallic frames of PV modules or other equipment shall be permitted to bond the exposed metal surfaces or other equipment to mounting structures. Metallic mounting structures, other than building steel, used for grounding purposes shall be identified as equipment-grounding conductors or shall have identified bonding jumpers or devices connected between the separate metallic sections and shall be bonded to the grounding system.

**(D) Photovoltaic Mounting Systems and Devices.** Devices and systems used for mounting PV modules that are also used to provide grounding of the module frames shall be identified for the purpose of grounding PV modules.

**(E) Adjacent Modules.** Devices identified and listed for bonding the metallic frames of PV modules shall be permitted

to bond the exposed metallic frames of PV modules to the metallic frames of adjacent PV modules.

**(F) All Conductors Together.** Equipment grounding conductors for the PV array and structure (where installed) shall be contained within the same raceway or cable or otherwise run with the PV array circuit conductors when those circuit conductors leave the vicinity of the PV array.

To maintain the shortest electrical time constant in each dc circuit, the equipment grounding conductor should be routed as closely as possible to the circuit conductors. This routing facilitates the operation of overcurrent devices.

### 690.45 Size of Equipment Grounding Conductors

Equipment grounding conductors for photovoltaic source and photovoltaic output circuits shall be sized in accordance with 690.45(A) or (B).

**(A) General.** Equipment grounding conductors in photovoltaic source and photovoltaic output circuits shall be sized in accordance with Table 250.122. Where no overcurrent protective device is used in the circuit, an assumed overcurrent device rated at the photovoltaic rated short-circuit current shall be used in Table 250.122. Increases in equipment grounding conductor size to address voltage drop considerations shall not be required. The equipment grounding conductors shall be no smaller than 14 AWG.

**(B) Ground-Fault Protection Not Provided.** For other than dwelling units where ground-fault protection is not provided in accordance with 690.5(A) through (C), each equipment grounding conductor shall have an ampacity of at least two (2) times the temperature and conduit fill corrected circuit conductor ampacity.

Equipment-grounding conductors on PV systems without ground-fault protection may have ground-fault currents that circulate continuously until the ground fault is corrected. These conductors must have their ampacity corrected for the conditions of use just like the circuit conductors. Fault currents from parallel source circuits may allow currents in equipment-grounding conductors up to twice the normal circuit current under ground-fault conditions.

**Informational Note:** The short-circuit current of photovoltaic modules and photovoltaic sources is just slightly above the full-load normal output rating. In ground-fault conditions, these sources are not able to supply the high levels of short-circuit or ground-fault currents necessary to quickly activate overcurrent devices as in typical ac systems. Protec-

tion for equipment grounding conductors in photovoltaic systems that are not provided with ground-fault protection is related to size and withstand capability of the equipment grounding conductor, rather than overcurrent device operation.

### 690.46 Array Equipment Grounding Conductors

Equipment grounding conductors for photovoltaic modules smaller than 6 AWG shall comply with 250.120(C).

### 690.47 Grounding Electrode System

**(A) Alternating-Current Systems.** If installing an ac system, a grounding electrode system shall be provided in accordance with 250.50 through 250.60. The grounding electrode conductor shall be installed in accordance with 250.64.

**(B) Direct-Current Systems.** If installing a dc system, a grounding electrode system shall be provided in accordance with 250.166 for grounded systems or 250.169 for ungrounded systems. The grounding electrode conductor shall be installed in accordance with 250.64.

A common dc grounding-electrode conductor shall be permitted to serve multiple inverters. The size of the common grounding electrode and the tap conductors shall be in accordance with 250.166. The tap conductors shall be connected to the common grounding-electrode conductor by exothermic welding or with connectors listed as grounding and bonding equipment in such a manner that the common grounding electrode conductor remains without a splice or joint.

**(C) Systems with Alternating-Current and Direct-Current Grounding Requirements.** Photovoltaic systems having dc circuits and ac circuits with no direct connection between the dc grounded conductor and ac grounded conductor shall have a dc grounding system. The dc grounding system shall be bonded to the ac grounding system by one of the methods in (1), (2), or (3).

This section shall not apply to ac PV modules.

When using the methods of (C)(2) or (C)(3), the existing ac grounding electrode system shall meet the applicable requirements of Article 250, Part III.

Informational Note No. 1: ANSI/UL 1741, *Standard for Inverters, Converters, and Controllers for Use in Independent Power Systems*, requires that any inverter or charge controller that has a bonding jumper between the grounded dc conductor and the grounding system connection point have that point marked as a grounding electrode conductor (GEC) connection point. In PV inverters, the terminals for the dc equipment grounding conductors and the terminals for ac equipment grounding conductors are generally connected to, or electrically in common with, a grounding busbar that has a marked dc GEC terminal.

Informational Note No. 2: For utility-interactive systems, the existing premises grounding system serves as the ac grounding system.

**(1) Separate Direct-Current Grounding Electrode System Bonded to the Alternating-Current Grounding Electrode System.** A separate dc grounding electrode or system shall be installed, and it shall be bonded directly to the ac grounding electrode system. The size of any bonding jumper(s) between the ac and dc systems shall be based on the larger size of the existing ac grounding electrode conductor or the size of the dc grounding electrode conductor specified by 250.166. The dc grounding electrode system conductor(s) or the bonding jumpers to the ac grounding electrode system shall not be used as a substitute for any required ac equipment grounding conductors.

**(2) Common Direct-Current and Alternating-Current Grounding Electrode.** A dc grounding electrode conductor of the size specified by 250.166 shall be run from the marked dc grounding electrode connection point to the ac grounding electrode. Where an ac grounding electrode is not accessible, the dc grounding electrode conductor shall be connected to the ac grounding electrode conductor in accordance with 250.64(C)(1). This dc grounding electrode conductor shall not be used as a substitute for any required ac equipment grounding conductors.

**(3) Combined Direct-Current Grounding Electrode Conductor and Alternating-Current Equipment Grounding Conductor.** An unspliced, or irreversibly spliced, combined grounding conductor shall be run from the marked dc grounding electrode conductor connection point along with the ac circuit conductors to the grounding busbar in the associated ac equipment. This combined grounding conductor shall be the larger of the sizes specified by 250.122 or 250.166 and shall be installed in accordance with 250.64(E).

Inverters used in PV power systems usually contain a transformer that isolates the dc grounded circuit conductor from the ac grounded circuit conductor. Isolation necessitates that both a dc and an ac grounding system be installed. The two grounding systems are to be bonded together or have a common grounding electrode so that all ac and dc grounded circuit conductors and equipment grounding conductors have the same near-zero potential to earth.

The combined dc equipment grounding, dc system grounding, and ac equipment grounding required by this section establishes only one grounding circuit and connection for the entire PV system from the PV array to the ac point of connection. Under PV dc ground-fault conditions, an interruption of this single circuit may allow exposed

metal surfaces to become energized up to the maximum PV system voltage.

### 690.48 Continuity of Equipment Grounding Systems

Where the removal of equipment disconnects the bonding connection between the grounding electrode conductor and exposed conducting surfaces in the photovoltaic source or output circuit equipment, a bonding jumper shall be installed while the equipment is removed.

PV source and output circuits are energized anytime the PV modules are exposed to light. The equipment grounding system is a primary line of defense against electric shocks and fires. In many PV systems, the main bonding jumper and the equipment grounding busbar are located in the inverter or a dc power center that may require removal for service. The continuity of the equipment grounding conductors should be maintained even when the equipment is removed.

### 690.49 Continuity of Photovoltaic Source and Output Circuit Grounded Conductors

Where the removal of the utility-interactive inverter or other equipment disconnects the bonding connection between the grounding electrode conductor and the photovoltaic source and/or photovoltaic output circuit grounded conductor, a bonding jumper shall be installed to maintain the system grounding while the inverter or other equipment is removed.

PV source and output circuits are energized anytime the PV modules are exposed to light. The marked, grounded circuit conductors should always remain grounded because they may be energized daily and cannot be easily disconnected from the source. In many PV systems, the main bonding jumper is located in the inverter or a dc power center that may require removal for service. The continuity to ground of the grounded circuit conductors should be maintained even when the equipment is removed.

### 690.50 Equipment Bonding Jumpers

Equipment bonding jumpers, if used, shall comply with 250.120(C).

## VI. Marking

### 690.51 Modules

Modules shall be marked with identification of terminals or leads as to polarity, maximum overcurrent device rating for module protection, and with the following ratings:

- (1) Open-circuit voltage
- (2) Operating voltage
- (3) Maximum permissible system voltage
- (4) Operating current
- (5) Short-circuit current
- (6) Maximum power

### 690.52 Alternating-Current Photovoltaic Modules

Alternating-current modules shall be marked with identification of terminals or leads and with identification of the following ratings:

- (1) Nominal operating ac voltage
- (2) Nominal operating ac frequency
- (3) Maximum ac power
- (4) Maximum ac current
- (5) Maximum overcurrent device rating for ac module protection

### 690.53 Direct-Current Photovoltaic Power Source

A permanent label for the direct-current photovoltaic power source indicating items (1) through (5) shall be provided by the installer at the photovoltaic disconnecting means:

- (1) Rated maximum power-point current
- (2) Rated maximum power-point voltage
- (3) Maximum system voltage

Informational Note to (3): See 690.7(A) for maximum photovoltaic system voltage.

- (4) Short-circuit current

Informational Note to (4): See 690.8(A) for calculation of maximum circuit current.

- (5) Maximum rated output current of the charge controller (if installed)

Informational Note: Reflecting systems used for irradiance enhancement may result in increased levels of output current and power.

After installation of PV arrays, it may be difficult to determine the system's rated voltage and current. These ratings, along with the open-circuit voltage and short-circuit current, are necessary to size the remainder of the system components, as specified elsewhere in Article 690. Generally, the marking described in 690.53 is required to be provided by the installer. The rated values for the PV power source can be calculated by adding voltage ratings of series-connected modules and adding current ratings of parallel-connected modules or PV source circuits.

Some charge controllers have higher rated output currents than the input currents from the PV array. They reduce

the input voltage from the PV array while increasing the output to the battery.

With respect to the informational note, a deliberate increase in the level of irradiance by reflectors or the like can cause the power source to operate at levels above those recommended by the manufacturer. See 110.3.

#### 690.54 Interactive System Point of Interconnection

All interactive system(s) points of interconnection with other sources shall be marked at an accessible location at the disconnecting means as a power source and with the rated ac output current and the nominal operating ac voltage.

#### 690.55 Photovoltaic Power Systems Employing Energy Storage

Photovoltaic power systems employing energy storage shall also be marked with the maximum operating voltage, including any equalization voltage and the polarity of the grounded circuit conductor.

#### 690.56 Identification of Power Sources

**(A) Facilities with Stand-Alone Systems.** Any structure or building with a photovoltaic power system that is not connected to a utility service source and is a stand-alone system shall have a permanent plaque or directory installed on the exterior of the building or structure at a readily visible location acceptable to the authority having jurisdiction. The plaque or directory shall indicate the location of system disconnecting means and that the structure contains a stand-alone electrical power system.

**(B) Facilities with Utility Services and PV Systems.** Buildings or structures with both utility service and a photovoltaic system shall have a permanent plaque or directory providing the location of the service disconnecting means and the photovoltaic system disconnecting means if not located at the same location.

### VII. Connection to Other Sources

#### 690.57 Load Disconnect

A load disconnect that has multiple sources of power shall disconnect all sources when in the off position.

#### 690.60 Identified Interactive Equipment

Only inverters and ac modules listed and identified as interactive shall be permitted in interactive systems.

#### 690.61 Loss of Interactive System Power

An inverter or an ac module in an interactive solar photovoltaic system shall automatically de-energize its output to the

connected electrical production and distribution network upon loss of voltage in that system and shall remain in that state until the electrical production and distribution network voltage has been restored.

A normally interactive solar photovoltaic system shall be permitted to operate as a stand-alone system to supply loads that have been disconnected from electrical production and distribution network sources.

The requirement of 690.61 prevents energizing of otherwise de-energized system conductors or output conductors of other off-site sources (e.g., an electrical utility) and is intended to prevent electric shock. This feature normally is provided as part of the utility-interactive inverter.

#### 690.63 Unbalanced Interconnections

Unbalanced connections shall be in accordance with 705.100.

#### 690.64 Point of Connection

Point of connection shall be in accordance with 705.12.

PV systems interconnected with other power production systems are also subject to the requirements of Article 705, including 705.12.

### VIII. Storage Batteries

#### 690.71 Installation

**(A) General.** Storage batteries in a solar photovoltaic system shall be installed in accordance with the provisions of Article 480. The interconnected battery cells shall be considered grounded where the photovoltaic power source is installed in accordance with 690.41.

#### (B) Dwellings.

**(1) Operating Voltage.** Storage batteries for dwellings shall have the cells connected so as to operate at less than 50 volts nominal. Lead-acid storage batteries for dwellings shall have no more than twenty-four 2-volt cells connected in series (48-volts nominal).

*Exception: Where live parts are not accessible during routine battery maintenance, a battery system voltage in accordance with 690.7 shall be permitted.*

**(2) Guarding of Live Parts.** Live parts of battery systems for dwellings shall be guarded to prevent accidental

contact by persons or objects, regardless of voltage or battery type.

**Informational Note:** Batteries in solar photovoltaic systems are subject to extensive charge–discharge cycles and typically require frequent maintenance, such as checking electrolyte and cleaning connections.

At any voltage, a primary safety concern in battery systems is that a fault (e.g., a metal tool dropped onto a terminal) might cause a fire or an explosion. *Guarded*, as defined in Article 100, describes the best method to reduce this hazard.

**(C) Current Limiting.** A listed, current-limiting, overcurrent device shall be installed in each circuit adjacent to the batteries where the available short-circuit current from a battery or battery bank exceeds the interrupting or withstand ratings of other equipment in that circuit. The installation of current-limiting fuses shall comply with 690.16.

**(D) Battery Nonconductive Cases and Conductive Racks.** Flooded, vented, lead-acid batteries with more than twenty-four 2-volt cells connected in series (48 volts, nominal) shall not use conductive cases or shall not be installed in conductive cases. Conductive racks used to support the nonconductive cases shall be permitted where no rack material is located within 150 mm (6 in.) of the tops of the nonconductive cases.

This requirement shall not apply to any type of valve-regulated lead-acid (VRLA) battery or any other types of sealed batteries that may require steel cases for proper operation.

Grounded metal trays and cases or containers (as normally required by 250.110) in flooded, lead-acid battery systems operating over 48 volts, nominal, have been shown to be a contributing factor in ground faults. Nonconductive racks, trays, and cases minimize this problem.

**(E) Disconnection of Series Battery Circuits.** Battery circuits subject to field servicing, where more than twenty-four 2-volt cells are connected in series (48 volts, nominal), shall have provisions to disconnect the series-connected strings into segments of 24 cells or less for maintenance by qualified persons. Non-load-break bolted or plug-in disconnects shall be permitted.

**(F) Battery Maintenance Disconnecting Means.** Battery installations, where there are more than twenty-four 2-volt cells connected in series (48 volts, nominal), shall have a disconnecting means, accessible only to qualified persons, that disconnects the grounded circuit conductor(s) in the bat-

tery electrical system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductor(s) for the remainder of the photovoltaic electrical system. A non-load-break-rated switch shall be permitted to be used as the disconnecting means.

**(G) Battery Systems of More Than 48 Volts.** On photovoltaic systems where the battery system consists of more than twenty-four 2-volt cells connected in series (more than 48 volts, nominal), the battery system shall be permitted to operate with ungrounded conductors, provided the following conditions are met:

- (1) The photovoltaic array source and output circuits shall comply with 690.41.
- (2) The dc and ac load circuits shall be solidly grounded.
- (3) All main ungrounded battery input/output circuit conductors shall be provided with switched disconnects and overcurrent protection.
- (4) A ground-fault detector and indicator shall be installed to monitor for ground faults in the battery bank.

## 690.72 Charge Control

**(A) General.** Equipment shall be provided to control the charging process of the battery. Charge control shall not be required where the design of the photovoltaic source circuit is matched to the voltage rating and charge current requirements of the interconnected battery cells and the maximum charging current multiplied by 1 hour is less than 3 percent of the rated battery capacity expressed in ampere-hours or as recommended by the battery manufacturer.

All adjusting means for control of the charging process shall be accessible only to qualified persons.

**Informational Note:** Certain battery types such as valve-regulated lead acid or nickel cadmium can experience thermal failure when overcharged.

### (B) Diversion Charge Controller.

**(1) Sole Means of Regulating Charging.** A photovoltaic power system employing a diversion charge controller as the sole means of regulating the charging of a battery shall be equipped with a second independent means to prevent overcharging of the battery.

**(2) Circuits with Direct-Current Diversion Charge Controller and Diversion Load.** Circuits containing a dc diversion charge controller and a dc diversion load shall comply with the following:

- (1) The current rating of the diversion load shall be less than or equal to the current rating of the diversion load charge controller. The voltage rating of the diversion load shall be greater than the maximum battery voltage. The power rating of the diversion load shall be at least 150 percent of the power rating of the photovoltaic array.

Diversion loads are typically rated by the current that they will draw at some rated voltage. If the rated current of the diversion load exceeds the current rating of the diversion load controller, the controller may not function properly.

- (2) The conductor ampacity and the rating of the overcurrent device for this circuit shall be at least 150 percent of the maximum current rating of the diversion charge controller.

If any portion of a diversion charge control system fails, the batteries may be overcharged and can create a potentially hazardous condition. Requiring a second, independent charge control method (usually a series regulator) and robust diversion controller circuits will minimize the potential problems.

**(3) PV Systems Using Utility-Interactive Inverters.** Photovoltaic power systems using utility-interactive inverters to control battery state-of-charge by diverting excess power into the utility system shall comply with (1) and (2):

- (1) These systems shall not be required to comply with 690.72(B)(2). The charge regulation circuits used shall comply with the requirements of 690.8.
- (2) These systems shall have a second, independent means of controlling the battery charging process for use when the utility is not present or when the primary charge controller fails or is disabled.

**(C) Buck/Boost Direct-Current Converters.** When buck/boost charge controllers and other dc power converters that increase or decrease the output current or output voltage with respect to the input current or input voltage are installed, the requirements shall comply with 690.72(C)(1) and (C)(2).

- (1) The ampacity of the conductors in output circuits shall be based on the maximum rated continuous output current of the charge controller or converter for the selected output voltage range.
- (2) The voltage rating of the output circuits shall be based on the maximum voltage output of the charge controller or converter for the selected output voltage range.

#### 690.74 Battery Interconnections

**(A) Flexible Cables.** Flexible cables, as identified in Article 400, in sizes 2/0 AWG and larger shall be permitted within the battery enclosure from battery terminals to a nearby junction box where they shall be connected to an approved wiring method. Flexible battery cables shall also be permitted between batteries and cells within the battery enclosure. Such cables shall be listed for hard-service use and identified as moisture resistant.

Flexible, fine-stranded cables shall be terminated only with terminals, lugs, devices, or connectors in accordance with 110.14(A).

Battery plates and terminals are sometimes constructed of relatively soft lead and lead alloys encased in plastics that are sealed with asphalt. Large-size, low-stranding stiff copper conductors attached to these components may cause them to be distorted. The use of flexible cables (see Article 400) may reduce the possibility of such distortions. Listed cables with the appropriate physical and chemical-resistant properties should be used. Welding and “battery” cables are not allowed or described in the *Code* for this use. Flexible “building wire”-type cables (Chapter 3) are also available and suitable for this use. Terminals intended for connection of stranded conductors using other than Class B and C stranding are required to be listed and marked for this use. Flexible, fine-stranded battery connection cables cannot be connected to terminals identified for use with conductors using the larger strands of conductors using Class B and C stranding. See the commentary on 690.31(F).

## IX. Systems over 600 Volts

### 690.80 General

Solar photovoltaic systems with a maximum system voltage over 600 volts dc shall comply with Article 490 and other requirements applicable to installations rated over 600 volts.

### 690.85 Definitions

For the purposes of Part IX of this article, the voltages used to determine cable and equipment ratings are as follows.

**Battery Circuits.** In battery circuits, the highest voltage experienced under charging or equalizing conditions.

**Photovoltaic Circuits.** In dc photovoltaic source circuits and photovoltaic output circuits, the maximum system voltage.

## I. General

### 692.1 Scope

This article identifies the requirements for the installation of fuel cell power systems, which may be stand-alone or interactive with other electric power production sources and may be with or without electric energy storage such as batteries. These systems may have ac or dc output for utilization.

The rising demand for electric power has led to the development of power sources that are viable alternatives to or can be interconnected with electric utility distribution systems. Article 692 covers the installation of on-premises electrical supply systems where the power is derived from an electrochemical system that consumes fuel to generate an electric current.

The principle of operation is that direct current is generated through a chemical reaction in which fuel such as natural gas or LP-Gas is consumed. As opposed to internal combustion prime movers, the consumption of the fuel gas is via an electrochemical process rather than a combustion process. A power inverter converts the dc to ac. The installation requirements of Article 692 allow power derived from fuel cells to be safely delivered into residential and light commercial occupancies as the sole source of electric power or as an integrated source with a utility or other power source.

### 692.2 Definitions

**Fuel Cell.** An electrochemical system that consumes fuel to produce an electric current. The main chemical reaction used in a fuel cell for producing electric power is not combustion. However, there may be sources of combustion used within the overall fuel cell system such as reformers/fuel processors.

**Fuel Cell System.** The complete aggregate of equipment used to convert chemical fuel into usable electricity. A fuel cell system typically consists of a reformer, stack, power inverter, and auxiliary equipment.

**Interactive System.** A fuel cell system that operates in parallel with and may deliver power to an electrical production and distribution network. For the purpose of this definition, an energy storage subsystem of a fuel cell system, such as a battery, is not another electrical production source.

**Maximum System Voltage.** The highest fuel cell inverter output voltage between any ungrounded conductors present at accessible output terminals.

**Output Circuit.** The conductors used to connect the fuel cell system to its electrical point of delivery. In the case of sites that have series- or parallel-connected multiple units, the term *output circuit* also refers to the conductors used to electrically interconnect the fuel cell system(s).

**Point of Common Coupling.** The point at which the power production and distribution network and the customer interface occurs in an interactive system. Typically, this is the load side of the power network meter.

**Stand-Alone System.** A fuel cell system that supplies power independently of an electrical production and distribution network.

### 692.3 Other Articles

Wherever the requirements of other articles of this *Code* and Article 692 differ, the requirements of Article 692 shall apply, and, if the system is operated in parallel with a primary source(s) of electricity, the requirements in 705.14, 705.16, 705.32, and 705.143 shall apply.

### 692.4 Installation

**(A) Fuel Cell System.** A fuel cell system shall be permitted to supply a building or other structure in addition to any service(s) of another electricity supply system(s).

**(B) Identification.** A permanent plaque or directory, denoting all electric power sources on or in the premises, shall be installed at each service equipment location.

**(C) System Installation.** Fuel cell systems including all associated wiring and interconnections shall be installed by only qualified persons.

Informational Note: See Article 100 for the definition of *qualified person*.

### 692.6 Listing Requirement

The fuel cell system shall be evaluated and listed for its intended application prior to installation.

Because the fuel cell system typically is a component of the premises wiring system, to facilitate its implementation into commercial use, 692.6 requires that the system be evaluated and listed for its intended use.

## II. Circuit Requirements

### 692.8 Circuit Sizing and Current

**(A) Nameplate Rated Circuit Current.** The nameplate(s) rated circuit current shall be the rated current indicated on the fuel cell nameplate(s).

**(B) Conductor Ampacity and Overcurrent Device Ratings.** The ampacity of the feeder circuit conductors from the fuel cell system(s) to the premises wiring system shall not be less than the greater of (1) nameplate(s) rated circuit current or (2) the rating of the fuel cell system(s) overcurrent protective device(s).

**(C) Ampacity of Grounded or Neutral Conductor.** If an interactive single-phase, 2-wire fuel cell output(s) is connected to the grounded or neutral conductor and a single ungrounded conductor of a 3-wire system or of a 3-phase, 4-wire, wye-connected system, the maximum unbalanced neutral load current plus the fuel cell system(s) output rating

shall not exceed the ampacity of the grounded or neutral conductor.

### 692.9 Overcurrent Protection

**(A) Circuits and Equipment.** If the fuel cell system is provided with overcurrent protection sufficient to protect the circuit conductors that supply the load, additional circuit overcurrent devices shall not be required. Equipment and conductors connected to more than one electrical source shall be protected.

**(B) Accessibility.** Overcurrent devices shall be readily accessible.

### 692.10 Stand-Alone Systems

The premises wiring system shall meet the requirements of this *Code* except as modified by 692.10(A), (B), and (C).

**(A) Fuel Cell System Output.** The fuel cell system output from a stand-alone system shall be permitted to supply ac power to the building or structure disconnecting means at current levels below the rating of that disconnecting means.

**(B) Sizing and Protection.** The circuit conductors between the fuel cell system(s) output and the building or structure disconnecting means shall be sized based on the output rating of the fuel cell system(s). These conductors shall be protected from overcurrents in accordance with 240.4. The overcurrent protection shall be located at the output of the fuel cell system(s).

**(C) Single 120-Volt Nominal Supply.** The inverter output of a stand-alone fuel cell system shall be permitted to supply 120 volts, nominal, to single-phase, 3-wire 120/240-volt service equipment or distribution panels where there are no 240-volt loads and where there are no multiwire branch circuits. In all installations, the rating of the overcurrent device connected to the output of the fuel cell system(s) shall be less than the rating of the service equipment. This equipment shall be marked as follows:

WARNING  
SINGLE 120-VOLT SUPPLY.  
DO NOT CONNECT MULTIWIRE  
BRANCH CIRCUITS!

## III. Disconnecting Means

### 692.13 All Conductors

Means shall be provided to disconnect all current-carrying conductors of a fuel cell system power source from all other conductors in a building or other structure.

### 692.17 Switch or Circuit Breaker

The disconnecting means for ungrounded conductors shall consist of readily accessible, manually operable switch(es) or circuit breaker(s).

Where all terminals of the disconnecting means may be energized in the open position, a warning sign shall be mounted on or adjacent to the disconnecting means. The sign shall be clearly legible and shall have the following words or equivalent:

DANGER  
ELECTRIC SHOCK HAZARD.  
DO NOT TOUCH TERMINALS.  
TERMINALS ON BOTH THE LINE AND  
LOAD SIDES MAY BE ENERGIZED  
IN THE OPEN POSITION.

## IV. Wiring Methods

### 692.31 Wiring Systems

All raceway and cable wiring methods included in Chapter 3 of this *Code* and other wiring systems and fittings specifically intended and identified for use with fuel cell systems shall be permitted. Where wiring devices with integral enclosures are used, sufficient length of cable shall be provided to facilitate replacement.

## V. Grounding

### 692.41 System Grounding

**(A) AC Systems.** Grounding of ac systems shall be in accordance with 250.20, and with 250.30 for stand-alone systems.

**(B) DC Systems.** Grounding of dc systems shall be in accordance with 250.160.

**(C) Systems with Alternating-Current and Direct-Current Grounding Requirements.** When fuel cell power systems have both alternating-current (ac) and direct-current (dc) grounding requirements, the dc grounding system shall be bonded to the ac grounding system. The bonding conductor shall be sized according to 692.45. A single common grounding electrode and grounding bar may be used for both systems, in which case the common grounding electrode conductor shall be sized to meet the requirements of both 250.66 (ac) and 250.166 (dc).

### 692.44 Equipment Grounding Conductor

A separate equipment grounding conductor shall be installed.

### 692.45 Size of Equipment Grounding Conductor

The equipment grounding conductor shall be sized in accordance with 250.122.

### 692.47 Grounding Electrode System

Any auxiliary grounding electrode(s) required by the manufacturer shall be connected to the equipment grounding conductor specified in 250.118.

## VI. Marking

### 692.53 Fuel Cell Power Sources

A marking specifying the fuel cell system, output voltage, output power rating, and continuous output current rating shall be provided at the disconnecting means for the fuel cell power source at an accessible location on the site.

### 692.54 Fuel Shut-Off

The location of the manual fuel shut-off valve shall be marked at the location of the primary disconnecting means of the building or circuits supplied.

### 692.56 Stored Energy

A fuel cell system that stores electric energy shall require the following warning sign, or equivalent, at the location of the service disconnecting means of the premises:

WARNING  
FUEL CELL POWER SYSTEM CONTAINS  
ELECTRICAL ENERGY STORAGE DEVICES.

## VII. Connection to Other Circuits

### 692.59 Transfer Switch

A transfer switch shall be required in non-grid-interactive systems that use utility grid backup. The transfer switch shall maintain isolation between the electrical production and distribution network and the fuel cell system. The transfer switch shall be permitted to be located externally or internally to the fuel cell system unit. Where the utility service conductors of the structure are connected to the transfer switch, the switch shall comply with Article 230, Part V.

### 692.60 Identified Interactive Equipment

Only fuel cell systems listed and marked as interactive shall be permitted in interactive systems.

### 692.61 Output Characteristics

Output characteristics shall be in accordance with 705.14.

•

### 692.62 Loss of Interactive System Power

The fuel cell system shall be provided with a means of detecting when the electrical production and distribution network has become de-energized and shall not feed the electrical production and distribution network side of the point of common coupling during this condition. The fuel

cell system shall remain in that state until the electrical production and distribution network voltage has been restored.

A normally interactive fuel cell system shall be permitted to operate as a stand-alone system to supply loads that have been disconnected from electrical production and distribution network sources.

#### 692.64 Unbalanced Interconnections

Unbalanced interconnections shall be in accordance with 705.100.

#### 692.65 Utility-Interactive Point of Connection

Point of connection shall be in accordance with 705.12.

### VIII. Outputs Over 600 Volts

#### 692.80 General

Fuel cell systems with a maximum output voltage over 600 volts ac shall comply with the requirements of other articles applicable to such installations.

I. General

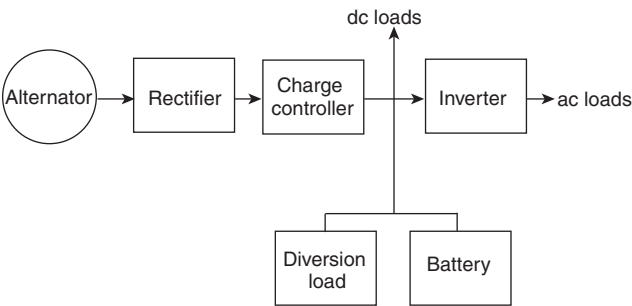

694.1 Scope

The provisions of this article apply to small wind (turbine) electric systems that consist of one or more wind electric generators with individual generators having a rated power up to and including 100 kW. These systems can include generators, alternators, inverters, and controllers.

Informational Note: Small wind electric systems can be interactive with other electrical power production sources or might be stand-alone systems. Small wind electric systems can have ac or dc output, with or without electrical energy storage, such as batteries. See Informational Note Figures 694.1, No. 1 and 694.1, No. 2.

INFORMATIONAL NOTE FIGURE 694.1, NO. 1  
Identification of Small Wind Electric System Components —  
Interactive System.

INFORMATIONAL NOTE FIGURE 694.1, NO. 2  
Identification of Small Wind Electric System Components —  
Stand-Alone System.

The inclusion of Article 694 in the 2011 *Code* provides a comprehensive set of installation requirements promoting safe use of this renewable energy source within premises wiring systems. Conversion of wind power to electricity is not new. It was used in rural farming areas prior to the Rural Electrification Act of 1936. Small wattage wind-powered generating systems, generally under 200 watts, were used to

charge storage batteries that in turn powered appliances on rural farms. In more recent times, wind-driven turbines have been implemented into the utility power generation portfolio to generate power using clean, renewable sources, which has become a priority in the United States and other countries.

Like photovoltaic and fuel cell systems, wind-driven turbines as a stand-alone or interconnected power production source are now available for use as part of the premises wiring system, and these systems have seen a significant increase in use. According to the U.S. Department of Energy’s 2007 annual report, the overall wind power capacity in the United States increased 46 percent in 2007. There is no reason that these systems will not continue to grow in popularity and use.

The American Wind Turbine Association classifies *small wind power* as being an individual turbine rated 100 kW or less. The individual wind turbines or generators are limited to 100 kW; however, the provisions of this article do not limit the number of generators or turbines that can be installed at any given location. Wind turbine farms are more common in the utility sector, while a small wind electric system consisting of a single wind turbine, such as the one shown in Exhibit 694.1, is the norm in most installations covered under the scope of this *Code*.

EXHIBIT 694.1 Small wind electric system consisting of a single wind turbine rated 100 kW or less. The system may be stand-alone or interconnected with a utility or other on-site source.

Article 694 contains the requirements for stand-alone and interconnected small wind systems, and many of the requirements are similar to those contained in Articles 690 and 692. This article also introduces specific terminology and requirements that address some of the safety concerns unique to this type of power generation system. For example, the elevated towers used to support the wind turbines

present lightning protection concerns in areas susceptible to thunderstorm activity.

## 694.2 Definitions

**Charge Controller.** Equipment that controls dc voltage or dc current, or both, and that is used to charge a battery or other energy storage device.

**Diversion Charge Controller.** Equipment that regulates the charging process of a battery or other energy storage device by diverting power from energy storage to dc or ac loads, or to an interconnected utility service.

**Diversion Load.** A load connected to a diversion charge controller or diversion load controller, also known as a dump load.

**Diversion Load Controller.** Equipment that regulates the output of a wind generator by diverting power from the generator to dc or ac loads or to an interconnected utility service.

**Guy.** A cable that mechanically supports a wind turbine tower.

**Inverter Output Circuit.** The conductors between an inverter and an ac panelboard for stand-alone systems, or the conductors between an inverter and service equipment or another electric power production source, such as a utility, for an electrical production and distribution network.

**Maximum Output Power.** The maximum 1 minute average power output a wind turbine produces in normal steady-state operation (instantaneous power output can be higher).

**Maximum Voltage.** The maximum voltage the wind turbine produces in operation including open circuit conditions.

**Nacelle.** An enclosure housing the alternator and other parts of a wind turbine.

**Rated Power.** The wind turbine's output power at a wind speed of 11 m/s (24.6 mph). If a turbine produces more power at lower wind speeds, the rated power is the wind turbine's output power at a wind speed less than 11 m/s that produces the greatest output power.

Informational Note: The method for measuring wind turbine power output is specified in IEC 61400-12-1, *Power Performance Measurements of Electricity Producing Wind Turbines*.

**Tower.** A pole or other structure that supports a wind turbine.

**Wind Turbine.** A mechanical device that converts wind energy to electrical energy.

**Wind Turbine Output Circuit.** The circuit conductors between the internal components of a small wind turbine

(which might include an alternator, integrated rectifier, controller, and/or inverter) and other equipment.

**Wind Turbine System.** A small wind electric generating system.

Informational Note: See also definitions for interconnected systems in Article 705.

## 694.3 Other Articles

Wherever the requirements of other articles of this *Code* and Article 694 differ, the requirements of Article 694 shall apply. Where the system is operated in parallel with primary sources of electricity, the requirements of Article 705 shall apply.

*Exception: Small wind electric systems, equipment, or wiring installed in a hazardous (classified) location shall also comply with the applicable portions of Articles 500 through 516.*

## 694.7 Installation

Systems covered by this article shall be installed only by qualified persons.

Informational Note: See Article 100 for the definition of *Qualified Person*.

Wind-powered systems present some unique hazards, including the danger of working in elevated confined spaces. Therefore, personnel working on these systems have to be trained to recognize and avoid all hazards associated with installation and servicing this type of power generation system.

**(A) Small Wind Electric Systems.** Small wind electric system(s) shall be permitted to supply a building or other structure in addition to any services of another electricity supply system.

**(B) Equipment.** Inverters used in small wind electric systems shall be identified and listed for the application.

Two documents published by Underwriters Laboratories — Subject 6140, *Outline of Investigation for Wind Turbine Generating Systems*, and Subject 6141, *Outline of Investigation for Wind Turbine Converters and Interconnection Systems* — provide the basis for certifying (product listing or classification) the overall wind turbine generator and its associated components or individual components such as inverters and interconnection hardware that are associated with a small wind generating system. At this time, the *NEC* only requires listing of inverters used in small wind electric systems.

**(C) Diversion Load Controllers.** A small wind electric system employing a diversion load controller as the primary means of regulating the speed of a wind turbine rotor shall be equipped with an additional, independent, reliable means to prevent over-speed operation. An interconnected utility service shall not be considered to be a reliable diversion load.

**(D) Surge Protective Devices (SPD).** A surge protective device shall be installed between a small wind electric system and any loads served by the premises electrical system. The surge protective device shall be permitted to be a Type 3 SPD on a dedicated branch circuit serving a small wind electric system or a Type 2 SPD located anywhere on the load side of the service disconnect. Surge protective devices shall be installed in accordance with Part II of Article 285.

For most installations, the decision to install surge protective devices (SPDs) is made by the designer, installer, or building owner. Because the towers associated with small wind electric systems will generally be quite high and possibly the tallest structure in the vicinity of the premises being supplied, the use of surge protection devices covered in Article 285 is mandatory in order to help protect the premises wiring systems against the effects of lightning. Grounding of towers and guy wires is covered in 694.40(B) and (C).

**(E) Receptacles.** A receptacle shall be permitted to be supplied by a small wind electric system branch or feeder circuit for maintenance or data acquisition use. Receptacles shall be protected with an overcurrent device with a rating not to exceed the current rating of the receptacle.

## II. Circuit Requirements

### 694.10 Maximum Voltage

**(A) Wind Turbine Output Circuits.** For wind turbines connected to one- and two-family dwellings, turbine output circuits shall be permitted to have a maximum voltage up to 600 volts. Other installations with a maximum voltage over 600 volts shall comply with Part IX of Article 694.

**(B) Direct-Current Utilization Circuits.** The voltage of dc utilization circuits shall comply with 210.6.

**(C) Circuits over 150 Volts to Ground.** In one- and two-family dwellings, live parts in circuits over 150 volts to ground shall not be accessible to other than qualified persons while energized.

Informational Note: See 110.27 for guarding of live parts and 210.6 for branch circuit voltage limitations.

### 694.12 Circuit Sizing and Current

**(A) Calculation of Maximum Circuit Current.** The maximum current for a circuit shall be calculated in accordance with 694.12(A)(1) through (A)(3).

**(1) Turbine Output Circuit Currents.** The maximum current shall be based on the circuit current of the wind turbine operating at maximum output power.

**(2) Inverter Output Circuit Current.** The maximum output current shall be the inverter continuous output current rating.

**(3) Stand-Alone Inverter Input Circuit Current.** The maximum input current shall be the stand-alone continuous inverter input current rating of the inverter producing rated power at the lowest input voltage.

**(B) Ampacity and Overcurrent Device Ratings.**

**(1) Continuous Current.** Small wind turbine electric system currents shall be considered to be continuous.

**(2) Sizing of Conductors and Overcurrent Devices.** Circuit conductors and overcurrent devices shall be sized to carry not less than 125 percent of the maximum current as calculated in 694.12(A). The rating or setting of overcurrent devices shall be permitted in accordance with 240.4(B) and (C).

*Exception: Circuits containing an assembly, together with its overcurrent devices, listed for continuous operation at 100 percent of its rating shall be permitted to be used at 100 percent of its rating.*

### 694.15 Overcurrent Protection

**(A) Circuits and Equipment.** Turbine output circuits, inverter output circuits, and storage battery circuit conductors and equipment shall be protected in accordance with the requirements of Article 240. Circuits connected to more than one electrical source shall have overcurrent devices located so as to provide overcurrent protection from all sources.

*Exception: An overcurrent device shall not be required for circuit conductors sized in accordance with 694.12(B) where the maximum current from all sources does not exceed the ampacity of the conductors.*

Informational Note: Possible backfeed of current from any source of supply, including a supply through an inverter to the wind turbine output circuit, is a consideration in determining whether adequate overcurrent protection from all sources is provided. Some small wind electric systems rely on the turbine output circuit to regulate turbine speed. Inverters may also operate in reverse for turbine startup or speed control.

**(B) Power Transformers.** Overcurrent protection for a transformer with sources on each side shall be provided in accordance with 450.3 by considering first one side of the transformer, then the other side of the transformer, as the primary.

*Exception: A power transformer with a current rating on the side connected to the inverter output, which is not less than the rated continuous output current rating of the inverter, shall not be required to have overcurrent protection at the inverter.*

**(C) Direct-Current Rating.** Overcurrent devices, either fuses or circuit breakers, used in any dc portion of a small wind electric system shall be listed for use in dc circuits and shall have appropriate voltage, current, and interrupting ratings.

### 694.18 Stand-Alone Systems

The premises wiring system shall be adequate to meet the requirements of this *Code* for a similar installation connected to a service. The wiring on the supply side of the building or structure disconnecting means shall comply with this *Code*, except as modified by 694.18(A) through (D).

**(A) Inverter Output.** The ac output from stand-alone inverters shall be permitted to supply ac power to the building or structure disconnecting means at current levels less than the calculated load connected to that disconnect. The inverter output rating or the rating of a wind energy source shall be not less than the load of the largest single utilization equipment connected to the system. Calculated general lighting loads shall not be considered as a single load.

The total calculated alternating current load is not required to be used in sizing the inverter of a stand-alone small wind electric system. The inverter of a stand-alone system is only required to be sized to supply the load of the largest single piece of utilization equipment. Larger inverters that will supply more of the ac load are, of course, permitted. This requirement parallels the rules for sizing the inverters of a stand-alone PV system specified in 690.10(A).

**(B) Sizing and Protection.** The circuit conductors between the inverter output and the building or structure disconnecting means shall be sized based on the output rating of the inverter. These conductors shall be protected in accordance with Article 240. The overcurrent protection shall be located at the output of the inverter.

**(C) Single 120-Volt Supply.** The inverter output of a stand-alone small wind electric system shall be permitted to supply

120 volts to single-phase, 3-wire, 120/240-volt service equipment or distribution panels where there are no 240-volt outlets and where there are no multiwire branch circuits. In all installations, the rating of the overcurrent device connected to the output of the inverter shall be less than the rating of the neutral bus in the service equipment. This equipment shall be marked with the following words or equivalent:

WARNING.  
SINGLE 120-VOLT SUPPLY.  
DO NOT CONNECT.  
MULTIWIRE BRANCH CIRCUITS!

Where only 120-volt loads are supplied, both ungrounded conductor busbars of a single-phase 120/240-volt, 3-wire panelboard or similar distribution equipment are permitted to be supplied by the same 120-volt ac inverter output. Because there is only a single 120-volt supply to both busbars, connecting circuits in a multiwire type arrangement will result in overloading of the neutral conductor — thus the prohibition on this type of circuit connection in the panelboard or similar distribution equipment.

**(D) Energy Storage or Backup Power System Requirements.** Energy storage or backup power supplies shall not be required.

## III. Disconnecting Means

### 694.20 All Conductors

Means shall be provided to disconnect all current-carrying conductors of a small wind electric power source from all other conductors in a building or other structure. A switch, circuit breaker, or other device, either ac or dc, shall not be installed in a grounded conductor if operation of that switch, circuit breaker, or other device leaves the marked, grounded conductor in an ungrounded and energized state.

*Exception: A wind turbine that uses the turbine output circuit for regulating turbine speed shall not require a turbine output circuit disconnecting means.*

### 694.22 Additional Provisions

Disconnecting means shall comply with 694.22(A) through (D).

**(A) Disconnecting Means.** The disconnecting means shall not be required to be suitable for use as service equipment. The disconnecting means for ungrounded conductors shall consist of manually operable switches or circuit breakers complying with all of the following requirements:

- (1) They shall be located where readily accessible.
- (2) They shall be externally operable without exposing the operator to contact with live parts.
- (3) They shall plainly indicate whether in the open or closed position.
- (4) They shall have an interrupting rating sufficient for the nominal circuit voltage and the current that is available at the line terminals of the equipment.

Where all terminals of the disconnecting means are capable of being energized in the open position, a warning sign shall be mounted on or adjacent to the disconnecting means. The sign shall be clearly legible and shall have the following words or equivalent:

WARNING.  
ELECTRIC SHOCK HAZARD.  
DO NOT TOUCH TERMINALS.  
TERMINALS ON BOTH THE LINE  
AND LOAD SIDES MAY BE  
ENERGIZED IN THE OPEN POSITION.

**(B) Equipment.** Equipment such as rectifiers, controllers, output circuit isolating and shorting switches, and over-current devices shall be permitted on the wind turbine side of the disconnecting means.

**(C) Requirements for Disconnecting Means.**

**(1) Location.** The small wind electric system disconnecting means shall be installed at a readily accessible location either on or adjacent to the turbine tower, on the outside of a building or structure or inside, at the point of entrance of the wind system conductors.

*Exception: Installations that comply with 694.30(C) shall be permitted to have the disconnecting means located remotely from the point of entry of the wind system conductors.*

A wind turbine disconnecting means shall not be required to be located at the nacelle or tower.

The disconnecting means shall not be installed in bathrooms.

The general requirement for locating the small wind electric system disconnecting means uses the same concept as found in 230.70(A) for services and 690.14(C)(1) for PV systems. The exception, which is the same as in 690.14(C)(1), permits the system disconnecting means to be located at any readily accessible location within a building or structure except a bathroom, provided the wiring method between the conductor point of entry and the disconnecting means is a metal raceway or the conductors are protected by a metal

enclosure. The wiring method provisions under which this installation is permitted are located in 694.30(C). The supply conductors from a turbine to a building or structure are permitted to be installed without a disconnecting means until they reach the building or structure.

**(2) Marking.** Each turbine system disconnecting means shall be permanently marked to identify it as a small wind electric system disconnect. A plaque shall be installed in accordance with 705.10.

**(3) Suitable for Use.** Turbine system disconnecting means shall be suitable for the prevailing conditions. Equipment installed in hazardous (classified) locations shall comply with the appropriate requirements of Articles 500 through 517.

**(4) Maximum Number of Disconnects.** The turbine disconnecting means shall consist of not more than six switches or six circuit breakers mounted in a single enclosure, in a group of separate enclosures, or in or on a switchboard.

**(D) Equipment That Is Not Readily Accessible.** Rectifiers, controllers, and inverters shall be permitted to be mounted in nacelles or other exterior areas that are not readily accessible.

## 694.24 Disconnection of Small Wind Electric System Equipment

Means shall be provided to disconnect equipment, such as inverters, batteries, and charge controllers, from all ungrounded conductors of all sources. If the equipment is energized from more than one source, the disconnecting means shall be grouped and identified.

A single disconnecting means in accordance with 694.22 shall be permitted for the combined ac output of one or more inverters in an interactive system.

A shorting switch or plug shall be permitted to be used as an alternative to a disconnect in systems that regulate turbine speed using the turbine output circuit.

*Exception: Equipment housed in a turbine nacelle shall not be required to have a disconnecting means.*

The exception permits equipment in the turbine nacelle (defined in 694.2) to be installed on the line side of the system or other disconnecting means. Depending on the size of the turbine, the space inside the nacelle can be limited, which reinforces the requirement for qualified persons to service small wind electric systems specified in 694.7.

**694.26 Fuses**

Means shall be provided to disconnect a fuse from all sources of supply where the fuse is energized from both directions and is accessible to other than qualified persons. Switches, pullouts, or similar devices that are rated for the application shall be permitted to serve as a means to disconnect fuses from all sources of supply.

**694.28 Installation and Service of a Wind Turbine**

Open circuiting, short circuiting, or mechanical brakes shall be used to disable a turbine for installation and service.

**Informational Note:** Some wind turbines rely on the connection from the alternator to a remote controller for speed regulation. Opening turbine output circuit conductors may cause mechanical damage to a turbine and create excessive voltages that could damage equipment or expose persons to electric shock.

**IV. Wiring Methods****694.30 Permitted Methods**

**(A) Wiring Systems.** All raceway and cable wiring methods included in this *Code*, and other wiring systems and fittings specifically intended for use on wind turbines, shall be permitted. In readily accessible locations, turbine output circuits that operate at voltages greater than 30 volts shall be installed in raceways.

**(B) Flexible Cords and Cables.** Flexible cords and cables, where used to connect the moving parts of turbines or where used for ready removal for maintenance and repair, shall comply with Article 400 and shall be of a type identified as hard service cord or portable power cable, shall be suitable for extra-hard usage, shall be listed for outdoor use, and shall be water resistant. Cables exposed to sunlight shall be sunlight resistant.

To provide a greater degree of flexibility, the conductors associated with flexible cords and cables are typically more finely stranded than conductors with Class B or C stranding. Terminals used with classes of stranding other than Class B or C are required to be identified for the class(es) of stranding for which they are suitable. See 110.14 and its associated commentary.

**(C) Direct-Current Turbine Output Circuits Inside a Building.** Direct-current turbine output circuits installed inside a building or structure shall be enclosed in metal raceways or installed in metal enclosures from the point of penetration of the surface of the building or structure to the first readily accessible disconnecting means.

The requirement for metal raceways or enclosures applies to all dc output circuits installed inside a building or structure regardless of the location of their disconnecting means. This requirement applies to all installations, including those where the disconnecting means location is at a readily accessible location nearest to where the conductors enter a building or structure. See the commentary following 694.22(C).

**V. Grounding****694.40 Equipment Grounding**

**(A) General.** Exposed non-current-carrying metal parts of towers, turbine nacelles, other equipment, and conductor enclosures shall be connected to an equipment grounding conductor in accordance with 250.134 or 250.136(A), regardless of voltage. Attached metal parts, such as turbine blades and tails that have no source of electrical energization, shall not be required to be connected to equipment grounding conductors.

**(B) Guy Wires.** Guy wires used to support turbine towers shall not be required to be connected to an equipment grounding conductor or to comply with the requirements of 250.110.

**Informational Note:** Guy wires supporting towers that are adequately grounded are unlikely to become energized. Grounding of metallic guy wires may be required by lightning codes. See 694.40(C)(4).

**(C) Tower Grounding.**

**(1) Auxiliary Electrodes.** A wind turbine tower shall be connected to one or more auxiliary electrodes to limit voltages imposed by lightning. Auxiliary electrodes shall be permitted to be installed in accordance with 250.54. Electrodes that are part of the tower foundation and meet the requirements for concrete encased electrodes in accordance with 250.52(A)(3) shall be acceptable. A grounded metal tower support shall be considered acceptable where meeting the requirements of 250.136(A). Where installed in close proximity to galvanized foundation or tower anchor components, galvanized grounding electrodes shall be used.

**Informational Note:** Copper and copper-clad grounding electrodes, where used in highly conductive soils, can cause electrolytic corrosion of galvanized foundation and tower anchor components.

This section requires that auxiliary grounding electrodes be installed at the wind turbine tower to provide lightning protection. The grounding electrode system at the tower is required to be connected to the equipment grounding conductor mandated by 694.40(C)(2).

**(2) Equipment Grounding Conductor.** An equipment grounding conductor shall be required between a turbine and the premises grounding system in accordance with 250.110.

**(3) Tower Grounding Connections.** Equipment grounding conductors and grounding electrode conductors, where used, shall be connected to the metallic tower by exothermic welding, listed lugs, listed pressure connectors, listed clamps, or other listed means. Devices, such as connectors and lugs, shall be suitable for the material of the conductor and the structure to which the devices are connected. Where practicable, contact of dissimilar metals shall be avoided anywhere in the system to eliminate the possibility of galvanic action and corrosion. All mechanical elements used to terminate these conductors shall be accessible.

**(4) Lightning Protection Systems.** Auxiliary electrodes and grounding electrode conductors shall be permitted to act as lightning protection system components where meeting applicable requirements. If separate, the tower lightning protection system grounding electrodes shall be bonded to the tower auxiliary grounding electrode system. Guy wires used as lightning protection system grounding electrodes shall not be required to be bonded to the tower auxiliary grounding electrode system.

Informational Note: See NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*, Informative Annex N, Wind Turbine Generator Systems, for information on lightning protection of wind turbines.

## VI. Marking

### 694.50 Interactive System Point of Interconnection

All interactive system points of interconnection with other sources shall be marked at an accessible location at the disconnecting means and with the rated ac output current and the nominal operating ac voltage.

### 694.52 Power Systems Employing Energy Storage

Small wind electric systems employing energy storage shall be marked with the maximum operating voltage, any equalization voltage, and the polarity of the grounded circuit conductor.

### 694.54 Identification of Power Sources

**(A) Facilities with Stand-Alone Systems.** Any structure or building with a stand-alone system and not connected to a utility service source shall have a permanent plaque or directory installed on the exterior of the building or structure at a

readily visible location. The plaque or directory shall indicate the location of system disconnecting means and shall indicate that the structure contains a stand-alone electrical power system.

**(B) Facilities with Utility Services and Small Wind Electric Systems.** Buildings or structures with both utility service and small wind electric systems shall have a permanent plaque or directory providing the location of the service disconnecting means and the small wind electric system disconnecting means.

### 694.56 Instructions for Disabling Turbine

A plaque shall be installed at or adjacent to the turbine location providing basic instructions for disabling the turbine.

The plaques or directories required by 694.54(A), 694.54(B), and 694.56 provide important information on the presence of a small wind electric system, the location of disconnecting means for all services and small wind electric systems that supply a premises, and on the means to disable the turbine. The information is important to those who are working on the premises wiring system and to first responders who need to know that multiple supply sources are present.

## VII. Connection to Other Sources

### 694.60 Identified Interactive Equipment

Only inverters listed and identified as interactive shall be permitted in interactive systems.

### 694.62 Installation

Small wind electric systems, where connected to utility electric sources, shall comply with the requirements of Article 705.

### 694.66 Operating Voltage Range

Small wind electric systems connected to dedicated branch or feeder circuits shall be permitted to exceed normal voltage operating ranges on these circuits, provided the voltage at any distribution equipment supplying other loads remains within normal ranges.

Informational Note: Wind turbines might use the electric grid to dump energy from short-term wind gusts. Normal operating voltages are defined in ANSI C84.1-2006, *Voltage Ratings for Electric Power Systems and Equipment* (60 Hz).

### 694.68 Point of Connection

Points of connection to interconnected electric power sources shall comply with 705.12.

## VIII. Storage Batteries

### 694.70 Installation

**(A) General.** Storage batteries in small wind electric systems shall comply with the provisions of Article 480.

#### **(B) Dwellings.**

**(1) Operating Voltage.** Storage batteries shall have the cells connected to operate at less than 50 volts nominal. Lead-acid storage batteries shall have no more than twenty-four 2-volt cells connected in series (48 volts, nominal).

*Exception: Where live parts are not accessible during routine battery maintenance, a battery system voltage in accordance with 694.10 shall be permitted.*

**(2) Guarding of Live Parts.** Live parts of battery systems shall be guarded to prevent accidental contact by persons or objects, regardless of voltage or battery type.

Informational Note: Batteries in small wind electric systems are subject to extensive charge/discharge cycles and typically require frequent maintenance, such as checking electrolyte and cleaning of connections.

**(C) Current Limiting.** A listed, current-limiting overcurrent device shall be installed in each circuit adjacent to the batteries when the available short-circuit current from a battery or battery bank exceeds the interrupting or withstand ratings of other equipment in that circuit. The installation of current-limiting fuses shall comply with 694.26.

**(D) Battery Nonconductive Cases and Conductive Racks.** Flooded, vented, lead-acid batteries with more than twenty-four 2-volt cells connected in series (48 volts, nominal) shall not use conductive cases or shall not be installed in conductive cases. Conductive racks used to support the nonconductive cases shall be permitted where rack material is not located within 150 mm (6 in.) of the tops of the nonconductive cases. This requirement shall not apply to any type of valve-regulated lead-acid (VRLA) battery or any other types of sealed batteries requiring steel or other conductive material cases for proper operation.

**(E) Disconnection of Series Battery Circuits.** Battery circuits subject to field servicing, with more than twenty-four 2-volt cells connected in series (48 volts, nominal), shall have provisions to disconnect the series-connected strings into segments of 24 cells or less for maintenance by qualified persons. Non-load-break bolted or plug-in disconnects shall be permitted.

**(F) Battery Maintenance Disconnecting Means.** Battery installations, with more than twenty-four 2-volt cells con-

nected in series (48 volts, nominal), shall have a disconnecting means, accessible only to qualified persons, that disconnects the grounded circuit conductors in the battery electrical system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductors for the remainder of the small wind electric system. A non-load-break-rated switch shall be permitted to be used as the disconnecting means.

**(G) Battery Systems of More Than 48 Volts.** Where the battery system for a small wind electric system consists of more than twenty-four 2-volt cells connected in series (more than 48 volts, nominal), the battery system shall be permitted to operate with ungrounded conductors, provided the following conditions are met:

- (1) The dc and ac load circuits are solidly grounded.
- (2) All main ungrounded battery input/output circuit conductors are provided with switched disconnects and overcurrent protection.
- (3) A ground-fault detector and indicator is installed to monitor for ground faults in the battery bank.

### 694.75 Charge Control

**(A) General.** Equipment shall be provided to control the charging process of the battery. Charge control shall not be required where the design of the small wind electric source is matched to the voltage rating and charge current requirements of the interconnected battery cells, and the maximum charging current, multiplied by 1 hour, is less than 3 percent of the rated battery capacity expressed in ampere-hours or as recommended by the battery manufacturer. All adjusting means for control of the charging process shall be accessible only to qualified persons.

Informational Note: Certain battery types, such as valve regulated lead-acid or nickel-cadmium, can experience thermal failure when overcharged.

#### **(B) Diversion Charge Controller.**

**(1) Sole Means of Regulating Charging.** A small wind electric system employing a diversion charge controller as the sole means of regulating the charging of a battery shall be equipped with two, reliable, independent means to prevent overcharging of the battery. An interconnected utility service shall not be considered to be a reliable diversion load.

**(2) Circuits with Direct-Current Diversion Charge Controller and Diversion Load.** Circuits containing a dc diversion charge controller and a dc diversion load shall comply with the following:

- (1) The current rating of the diversion load shall not be greater than the current rating of the diversion load

charge controller. The voltage rating of the diversion load shall be greater than the maximum battery voltage. The power rating of the diversion load shall be not less than 150 percent of the maximum power output rating of the small wind electric system.

- (2) The conductor ampacity and the rating of the overcurrent device for this circuit shall be at least 150 percent of the maximum current rating of the diversion charge controller.

## IX. Systems over 600 Volts

### 694.80 General

Small wind electric systems with a maximum system voltage exceeding 600 volts ac or dc shall comply with Article 490 and other requirements applicable to installations rated over 600 volts.

### 694.85 Cable and Equipment Ratings

For the purposes of Part IX of this article, the voltages used to determine cable and equipment ratings shall be as specified in 694.85(A) and (B).

**(A) Battery Circuits.** In battery circuits, the voltage used shall be the highest voltage experienced under charging or equalizing conditions.

**(B) Other Circuits.** In other circuits, the voltage used shall be the maximum voltage experienced in normal operation.

### 695.1 Scope

Informational Note: Text that is followed by a reference in brackets has been extracted from NFPA 20-2010, *Standard for the Installation of Stationary Pumps for Fire Protection*. Only editorial changes were made to the extracted text to make it consistent with this *Code*.

**(A) Covered.** This article covers the installation of the following:

- (1) Electric power sources and interconnecting circuits
- (2) Switching and control equipment dedicated to fire pump drivers

**(B) Not Covered.** This article does not cover the following:

- (1) The performance, maintenance, and acceptance testing of the fire pump system, and the internal wiring of the components of the system
- (2) Pressure maintenance (jockey or makeup) pumps

Informational Note: See NFPA 20-2010, *Standard for the Installation of Stationary Pumps for Fire Protection*, for further information.

Since it was first included in the 1996 *NEC*, Article 695 has been the subject of a number of important revisions, particularly in the requirements covering reliable power supplies for electric fire pump motors. Those revisions correlate the requirements in the *NEC* with those in NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*.

One of the most significant changes that has occurred in the evolution of Article 695 is the requirement of 695.3(C) covering reliable power for electric fire pumps installed in multibuilding campus-style arrangements such as those found in many institutional and industrial settings. This revision allows for fire pumps to be supplied by feeder circuits that are part of a high or medium voltage premises wiring system. This distribution arrangement is quite common in industrial and institutional campus settings. The conductors supplied by the higher voltage level distribution systems are not service conductors, because the service point and service-disconnecting means is generally located at a campus distribution switchyard or distribution building. Also, all of the distribution conductors on the load side of the service equipment, even though they resemble electric utility-type distribution, are considered to be feeders or in some cases where the circuit supplies a single piece of utilization equipment, branch circuits.

Noteworthy is the distinct division of responsibility for fire pump requirements between the *NEC* and NFPA 20. Performance issues, including the determination of power-supply reliability, are under the jurisdiction of the NFPA Technical Committee on Fire Pumps, while electrical installation requirements are within the purview of the National Electrical Code Committee. The scope of Article 695, stated in 695.1, speaks to this division of responsibility.

Article 695 does not apply to pumps used to supply sprinkler systems in one- and two-family dwellings. NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, does not require the use of a listed pump; thus, neither NFPA 20 nor Article 695 is applicable. Although the installation requirements for pressure maintenance (jockey) pumps are not covered by Article 695, there are provisions in Article 695 permitting these pumps to be supplied by a fire pump service or feeder.

Other than the specific reference in 695.4(B)(3)(b), the requirements of Article 695 are independent of those in Article 700 unless otherwise mandated by the authority having jurisdiction. Installation of the supply wiring to an electric motor-driven fire pump such as the one shown in Exhibit 695.1 is covered by the requirements of Article 695.

**EXHIBIT 695.1** An electric motor specifically listed for fire pump service. (Courtesy of Liberty Mutual Risk Engineering)

## 695.2 Definitions

**Fault-Tolerant External Control Circuits.** Those control circuits either entering or leaving the fire pump controller enclosure, which if broken, disconnected, or shorted will not prevent the controller from starting the fire pump from all other internal or external means and may cause the controller to start the pump under these conditions.

**On-Site Power Production Facility.** The normal supply of electric power for the site that is expected to be constantly producing power.

**On-Site Standby Generator.** A facility producing electric power on site as the alternate supply of electric power. It differs from an on-site power production facility, in that it is not constantly producing power.

## 695.3 Power Source(s) for Electric Motor-Driven Fire Pumps

Electric motor-driven fire pumps shall have a reliable source of power.

**(A) Individual Sources.** Where reliable, and where capable of carrying indefinitely the sum of the locked-rotor current of the fire pump motor(s) and the pressure maintenance pump motor(s) and the full-load current of the associated fire pump accessory equipment when connected to this power supply, the power source for an electric motor driven fire pump shall be one or more of the following.

The power source for an electric motor-driven fire pump must be reliable and have adequate capacity to carry the locked-rotor currents of the fire pump motor and accessory

equipment. These two main requirements ensure that the fire pump will operate in the event of a fire without being accidentally disconnected, and that the fire pump will continue to operate until the fire is extinguished, the fire pump is purposely shut down, or the pump itself is destroyed.

The determination of whether the serving electric utility is a reliable source of power is an issue for the authority having jurisdiction. Section A.9.3.2 in Annex A of NFPA 20-2010, *Standard for the Installation of Stationary Pumps for Fire Protection*, elaborates on several key characteristics of a reliable power supply.

**Excerpt from Annex A of NFPA 20-2010,  
Standard for the Installation of Stationary  
Pumps for Fire Protection**

**A.9.3.2** A reliable power source possesses the following characteristics:

- (1) The source power plant has not experienced any shutdowns of longer than 4 continuous hours in the year prior to plan submittal. NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, requires special undertakings (i.e., fire watches) when a water-based fire protection system is taken out of service for longer than 4 hours. If the normal source power plant has been intentionally shut down for longer than 4 hours in the past, it is reasonable to require a backup source of power.
- (2) No power outages have been experienced in the area of the protected facility caused by failures in the power grid that were not due to natural disasters or electric grid management failure. The standard does not require that the normal source of power is infallible. NFPA 20 does not intend to require a back-up source of power for every installation using an electric motor-driven fire pump. Should the normal source of power fail due to a natural disaster (hurricane) or due to a problem with electric grid management (regional blackout), the fire protection system could be supplied through the fire department connection. However, if the power grid is known to have had problems in the past (i.e., switch failures or animals shorting a substation), it is reasonable to require a backup source of power.
- (3) The normal source of power is not supplied by overhead conductors outside the protected facility. Fire departments responding to an incident at the protected facility will not operate aerial apparatus near live overhead power lines, without exception. A backup source of power is required in case this scenario occurs and the normal source of power must be shut off. Additionally, many utility providers will remove power to the protected facility by physically cutting the overhead conductors. If the normal source of power is provided by overhead conduc-

tors, which will not be identified, the utility provider could mistakenly cut the overhead conductor supplying the fire pump.

- (4) Only the disconnect switches and overcurrent protection devices permitted by 9.2.3 are installed in the normal source of power. Power disconnection and activated overcurrent protection should only occur in the fire pump controller. The provisions of 9.2.2 for the disconnect switch and overcurrent protection essentially require disconnection and overcurrent protection to occur in the fire pump controller. If unanticipated disconnect switches or overcurrent protection devices are installed in the normal source of power that do not meet the requirements of 9.2.2, the normal source of power must be considered not reliable and a back-up source of power is necessary.

Performance requirements for the alternate source of electric power can be found in NFPA 110, *Standard for Emergency and Standby Power Systems*.

For an on-site power production facility to be considered a reliable power source for an electric motor-driven fire pump(s), fire protection measures must be in place to protect the source and maintain a reliable power supply. In many cases, on-site power production sources are electric generating stations dedicated to a particular facility or to a particular facility's campus-style distribution system. Information on fire protection systems for on-site generating stations can be found in NFPA 850-2010, *Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations*. The requirements for fire protection of the fire pump supply conductors are located in 695.6(A) and (B).

**(1) Electric Utility Service Connection.** A fire pump shall be permitted to be supplied by a separate service, or from a connection located ahead of and not within the same cabinet, enclosure, or vertical switchboard section as the service disconnecting means. The connection shall be located and arranged so as to minimize the possibility of damage by fire from within the premises and from exposing hazards. A tap ahead of the service disconnecting means shall comply with 230.82(5). The service equipment shall comply with the labeling requirements in 230.2 and the location requirements in 230.72(B). [20:9.2.2(1)]

The top example in Exhibit 695.2 shows a single service where a dedicated set of service conductors to supply the fire pump is tapped to the incoming service conductors. The tap cannot be made in the section of the equipment that contains the service disconnecting means. This tap is permitted

**EXHIBIT 695.2** Two permitted configurations for connecting to an electric utility-supplied service.

under the conditions specified in 230.40, Exception No. 5 and 230.82(5). The bottom example shows a dedicated service to supply the fire pump. A separate service for the fire pump is permitted by 230.2(A)(1).

**(2) On-Site Power Production Facility.** A fire pump shall be permitted to be supplied by an on-site power production facility. The source facility shall be located and protected to minimize the possibility of damage by fire. [20:9.2.2(3)]

*On-site power production facilities* are defined in 695.2 and are permitted to be used as the sole power source for an electrically driven fire pump motor. An on-site power production facility differs in normal application from an on-site standby generator, in that it is the normal source of electrical supply for a building, structure, or campus and is

not a utility-owned generating facility. For some small installations, the normal use of the generator is the distinguishing feature between whether the equipment is defined as an on-site power production facility or an on-site standby generator. Exhibit 695.3 illustrates generating equipment that is the normal source of power for the premises wiring system and meets the definition of on-site power production facility.

**(3) Dedicated Feeder.** A dedicated feeder shall be permitted where it is derived from a service connection as described in 695.3(A)(1). [20:9.2.2(3)]

One or more of the following types of power sources are permitted to individually supply an electrically driven fire pump. If only one source is used, that source must be capable

**EXHIBIT 695.3** On-site power production facility as a power source for a fire pump installation.

of supplying locked-rotor current to the fire pump and accessory equipment. Power may be supplied by the following:

1. A separate utility service or connection ahead of the main disconnecting means
2. An on-site power production system
3. A feeder dedicated to the fire pump that is supplied by a service meeting the requirements of 695.3(A)(1).

**(B) Multiple Sources.** If reliable power cannot be obtained from a source described in 695.3(A), power shall be supplied by one of the following: [20:9.3.2]

**(1) Individual Sources.** An approved combination of two or more of the sources from 695.3(A).

Where the alternate source of power is an on-site standby generator, the alternate source disconnecting means and the alternative source overcurrent protective device(s) for the electric-drive fire pump are not required to be sized for locked-rotor current of the fire pump motor(s). The generator is required to be sized to allow the fire pump to start and run per 9.6.1.1 in NFPA 20-2010, *Standard for the Installation of Stationary Pumps for Fire Protection*. The associated circuit components are required to be sized according to Article 430 and to “allow instantaneous pickup of the full [fire] pump room load.” This requirement is also found in 9.6.5 in NFPA 20-2010.

**(2) Individual Source and On-site Standby Generator.**

An approved combination of one or more of the sources in 695.3(A) and an on-site standby generator complying with 695.3(D). [20:9.3.4]

*Exception to (B)(1) and (B)(2): An alternate source of power shall not be required where a back-up engine-driven or back-up steam turbine-driven fire pump is installed. [20:9.3.3]*

If none of the power supply sources specified in 695.3(A)(1) through (3) can individually provide reliable power with adequate capacity, 695.3(B) permits an approved combination (two or more) of these sources or a combination of one or more of these sources with an on-site standby generator. A back-up engine- or steam turbine-driven fire pump is permitted in lieu of installing an on-site standby generator; therefore, the electric fire pump is required to be supplied by only a single power source. This allowance provides some design options on how to augment an electric fire pump that is supplied by a source that has not been deemed to be reliable.

**(C) Multibuilding Campus-Style Complexes.** If the sources in 695.3(A) are not practicable and the installation is part of a multibuilding campus-style complex, feeder sources shall be permitted if approved by the authority having jurisdiction and installed in accordance with either (C)(1) and (C)(3) or (C)(2) and (C)(3).

**(1) Feeder Sources.** Two or more feeders shall be permitted as more than one power source if such feeders are con-

nected to, or derived from, separate utility services. The connection(s), overcurrent protective device(s), and disconnecting means for such feeders shall meet the requirements of 695.4(B).

**(2) Feeder and Alternate Source.** A feeder shall be permitted as a normal source of power if an alternate source of power independent from the feeder is provided. The connection(s), overcurrent protective device(s), and disconnecting means for such feeders shall meet the requirements of 695.4(B).

**(3) Selective Coordination.** The overcurrent protective device(s) in each disconnecting means shall be selectively coordinated with any other supply-side overcurrent protective device(s).

The requirements of 695.3(C) permit the use of feeder (see definition in Article 100) sources for multibuilding campus-style applications. This method of power supply requires the approval of the authority having jurisdiction.

A fire pump supplied by a radial loop type of distribu-

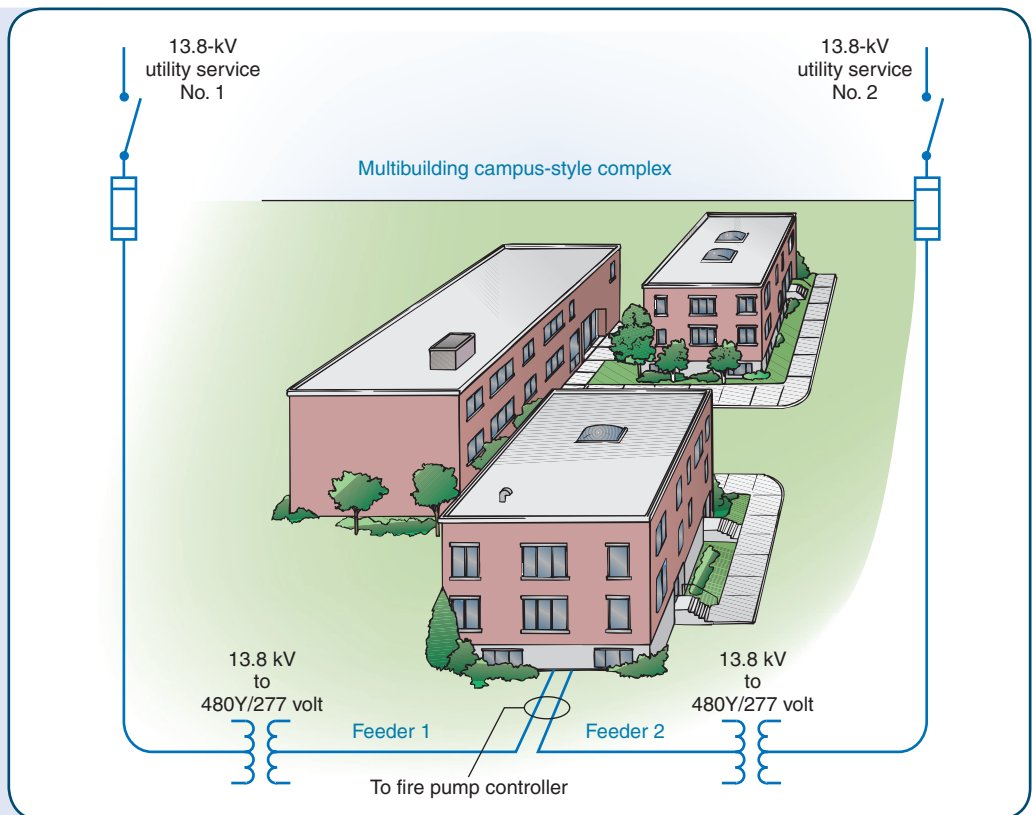

tion system (commonly used for medium and high voltage distribution) where the two feeders originate from a single substation has to be augmented by an on-site standby generator in order for the power supply to be deemed reliable. In the system shown in Exhibit 695.4, the two feeders originate from different utility services, a distribution arrangement that allows the two feeders, without an on-site standby generator, to be the single source for the electric fire pump as permitted by 695.3(C)(1).

Where there is more than one overcurrent device in series with the fire pump supply, 695.3(C)(3) requires each device to be selectively coordinated with supply-side overcurrent protective devices.

**(D) On-Site Standby Generator as Alternate Source.** An on-site standby generator(s) used as an alternate source of power shall comply with (D)(1) through (D)(3). [20:9.6.2.1]

**(1) Capacity.** The generator shall have sufficient capacity to allow normal starting and running of the motor(s) driving the fire pump(s) while supplying all other simultaneously operated load(s). [20:9.6.1.1]

**EXHIBIT 695.4** Multiple feeder sources for campus-style application, as described in 695.3(C)(1).

Automatic shedding of one or more optional standby loads in order to comply with this capacity requirement shall be permitted.

On-site standby generators are required only to be capable of carrying the starting and running current of the fire pump motor. Only the sources specified in 695.3(A)(1) through (3) are required to be capable of indefinitely carrying the locked rotor current of the fire pump motor.

**(2) Connection.** A tap ahead of the generator disconnecting means shall not be required. [20:9.6.1.2]

**(3) Adjacent Disconnects.** The requirements of 430.113 shall not apply.

**(E) Arrangement.** All power supplies shall be located and arranged to protect against damage by fire from within the premises and exposing hazards. [20:9.1.4]

Multiple power sources shall be arranged so that a fire at one source does not cause an interruption at the other source.

Determining compliance with this performance requirement has to take into account individual building or structure characteristics including, but not limited to, the type of construction, type of content, proximity of building to other hazard exposures, and the location of the primary and alternate power sources for the fire pump.

**(F) Phase Converters.** Phase converters shall not be permitted to be used for fire pump service. [20:9.1.7]

Concern over voltage imbalance between phases under unloaded or lightly loaded conditions is the reason phase converters are not permitted for fire pump service. This condition could adversely impact electronics integral to the controller. Because the controller has to be constantly powered, a phase converter used in a fire pump circuit would be in continuous operation.

## 695.4 Continuity of Power

Circuits that supply electric motor-driven fire pumps shall be supervised from inadvertent disconnection as covered in 695.4(A) or (B).

**(A) Direct Connection.** The supply conductors shall directly connect the power source to either a listed fire pump controller or listed combination fire pump controller and power transfer switch.

## **(B) Connection Through Disconnecting Means and Overcurrent Device.**

Section 695.4(B) permits, but does not require, the installation of a disconnecting means and associated overcurrent protection between a power source and the fire pump control devices described in 695.4(B)(1). Other requirements in the *Code* such as 230.70 and 225.31 may necessitate the installation of the disconnecting means and overcurrent protection covered in the requirements of 695.4(B). Ideal, but not always possible, would be the direct connection of the source to the fire pump control equipment in accordance with 695.4(A).

### **(1) Number of Disconnecting Means.**

(a) **General.** A single disconnecting means and associated overcurrent protective device(s) shall be permitted to be installed between the fire pump power source(s) and one of the following: [20:9.1.2]

- (1) A listed fire pump controller
- (2) A listed fire pump power transfer switch
- (3) A listed combination fire pump controller and power transfer switch

(b) **Feeder Sources.** For systems installed under the provisions of 695.3(C) only, additional disconnecting means and the associated overcurrent protective device(s) shall be permitted as required to comply with other provisions of this *Code*.

(c) **On-Site Standby Generator.** Where an on-site standby generator is used to supply a fire pump, an additional disconnecting means and an associated overcurrent protective device(s) shall be permitted.

This provision allows an on-site standby generator to be equipped with an integral disconnecting means and overcurrent protection that is in addition to a disconnecting means and overcurrent protection installed elsewhere in the alternate supply circuit to the fire pump. Alternatively, this disconnecting means could be located in distribution equipment that is supplied from a generator or multiple generators connected in parallel. The disconnecting means permitted by this section is required to comply with the requirements of 695.4(B)(2)(a) and 695.4(B)(3)(b) through (e).

**(2) Overcurrent Device Selection.** Overcurrent devices shall comply with (a) or (b).

(a) **Individual Sources.** The overcurrent protective device(s) shall be rated to carry indefinitely the sum of the locked-rotor current of the fire pump motor(s) and the pressure maintenance pump motor(s) and the full-load current

of the associated fire pump accessory equipment when connected to this power supply. Where the locked-rotor current value does not correspond to a standard overcurrent device size, the next standard overcurrent device size shall be used in accordance with 240.6. The requirement to carry the locked-rotor currents indefinitely shall not apply to conductors or devices other than overcurrent devices in the fire pump motor circuit(s). [20:9.2.3.4]

The requirement for sizing the overcurrent protection in a supervised fire pump disconnecting means so it is able to carry locked-rotor current indefinitely is a key factor in the reliable power source equation. Due to the critical life safety and property protection function of a fire pump, opening of the circuit by an overcurrent device installed between the point of connection to the power source and the fire pump controller cannot be tolerated and the circuit has to perform as if there were a direct connection to the power source. Sizing for locked-rotor current applies only to overcurrent protective devices and does not extend to conductors or other devices in the fire pump motor circuit. Similar provisions to this effect are contained in 695.5(B) and 695.5(C)(2).

(b) *On-Site Standby Generators.* Overcurrent protective devices between an on-site standby generator and a fire pump controller shall be selected and sized to allow for instantaneous pickup of the full pump room load, but shall not be larger than the value selected to comply with 430.62 to provide short-circuit protection only. [20:9.6.1.1]

This requirement correlates with 695.3(D)(1) covering the required capacity of an on-site standby generator. Overcurrent protective devices supplied by an on-site standby generator are not required to be sized to carry the locked rotor current of the fire pump(s) indefinitely. The on-site standby generator is not limited to supplying only the fire pump, but where other pump room loads are supplied, it must have sufficient capacity to instantaneously carry the entire load supplied. The overcurrent protective devices are not required to provide overload protection and are required to be sized per 430.62, which covers devices supplying multiple motors or motors and other loads.

**(3) Disconnecting Means.** All disconnecting devices that are unique to the fire pump loads shall comply with items (a) through (e).

(a) *Features and Location — Normal Power Source.* The disconnecting means for the normal power source shall comply with all of the following: [20:9.2.3.1]

- (1) Be identified as suitable for use as service equipment
- (2) Be lockable in the closed position
- (3) Not be located within equipment that feeds loads other than the fire pump
- (4) Be located sufficiently remote from other building or other fire pump source disconnecting means such that inadvertent operation at the same time would be unlikely

A supervised disconnecting means supplied by one of the individual sources specified in 695.3(A) cannot be installed in distribution equipment that supplies other than fire pump loads. This requirement provides clear direction on how compliance with 695.4(B)(3)(a)(4) can be achieved. “Sufficiently remote from other building or other fire pump source disconnecting means” cannot be interpreted as permitting a supervised fire pump disconnecting means to be located in a switchboard or panelboard that supplies other than fire pump loads.

(b) *Features and Location — On-Site Standby Generator.* The disconnecting means for an on-site standby generator(s) used as the alternate power source shall be installed in accordance with 700.10(B)(5) for emergency circuits and shall be lockable in the closed position.

A disconnecting means supplied by an on-site standby generator is permitted to be installed in equipment that supplies other loads. However, the requirements of 700.10(B)(5) must be followed. The effect of this requirement is that a fire pump feeder cannot be supplied from equipment in which the fire pump conductors are installed in the same enclosure or vertical switchboard section with conductors supplying loads that are designated or classed as legally required standby (Article 701) or optional standby (Article 702) loads. To help minimize inadvertent opening of the fire pump circuit, the disconnecting means is required to be capable of being locked in the closed (on) position.

(c) *Disconnect Marking.* The disconnecting means shall be marked “Fire Pump Disconnecting Means.” The letters shall be at least 25 mm (1 in.) in height, and they shall be visible without opening enclosure doors or covers. [20:9.2.3.1(5)]

(d) *Controller Marking.* A placard shall be placed adjacent to the fire pump controller, stating the location of this disconnecting means and the location of the key (if the disconnecting means is locked). [20:9.2.3.2]

(e) *Supervision.* The disconnecting means shall be supervised in the closed position by one of the following methods:

- (1) Central station, proprietary, or remote station signal device
- (2) Local signaling service that causes the sounding of an audible signal at a constantly attended point
- (3) Locking the disconnecting means in the closed position
- (4) Sealing of disconnecting means and approved weekly recorded inspections when the disconnecting means are located within fenced enclosures or in buildings under the control of the owner [20:9.2.3.3]

Minimizing the locations where the power supply to the fire pump can be automatically or manually interrupted is the objective of 695.4. Ideally, the supply conductors from the power source are run directly to the listed fire pump control and/or transfer equipment, without the need for an additional service disconnecting means and overcurrent protection. However, this arrangement is not always possible; therefore, a single supervised disconnecting means is permitted, provided all the conditions in 695.4(B) are met.

Where installed in the fire pump circuit, the supervised disconnecting means with overcurrent protection must meet the following conditions:

1. Overcurrent device is sized to carry the locked-rotor currents of all the fire pump motors.
2. Fire pump disconnecting means is located away from the other service disconnecting means. This disconnecting means is rated as service equipment and is lockable in the “on” position.
3. Equipment containing the disconnecting means supplies only the fire pump and associated loads.
4. Disconnect and controller are marked and placarded as described.
5. Circuit is supervised in the closed position, in accordance with 695.4(B)(3)(e).

The size of the overcurrent protective device is the sum of the locked-rotor currents of all the permitted motors plus the sum of any other fire pump auxiliary loads.

#### Calculation Example

A fusible service disconnect switch supplies power to a 100-hp, 460-volt, 3-phase fire pump and to a 1½-hp, 460-volt, 3-phase jockey pump. The fire pump feeder circuit will be installed in a raceway between the disconnecting means and fire pump controller. The raceway is considered outside the building per 230.6. Using the requirements of Article 695, determine the sizes of the disconnecting means and overcurrent protection device. Also determine the minimum ampacity of the feeder conductors.

#### Solution

STEP 1. Determine the minimum ratings of the disconnecting means and the overcurrent protective device.

According to the motor nameplates, the locked-rotor current (LRC) is 725 amperes for the 100-hp motor and 20 amperes for the 1½-hp motor. If the locked-rotor amperes are not on the nameplates, the locked-rotor currents found in Table 430.251(B) must be used. Calculate the size by summing the locked-rotor currents of both motors and then going to the next larger standard-size overcurrent device, as follows:

$$100\text{-hp, 3-phase LRC} = 725 \text{ A}$$

$$1\frac{1}{2}\text{-hp, 3-phase LRC} = \underline{20 \text{ A}}$$

$$\text{Total LRC} = 745 \text{ A}$$

The next larger standard-size disconnect switch and overcurrent device is 800 amperes. An adjustable-trip circuit breaker of 750 amperes is also permitted, because it, too, will carry the locked-rotor current indefinitely.

STEP 2. Determine the minimum ampacity for the fire pump feeder conductor.

Even though the disconnect switch, fuse, and circuit breakers are sized according to locked-rotor currents, the feeder conductors to the fire pump and associated equipment are required to have an ampacity not less than 125 percent of the full-load current (FLC) rating of the fire pump motor(s) and pressure maintenance pump motor(s), plus 100 percent of associated accessory equipment. Using the same motors as in Step 1, calculate the size of the feeder to the fire pump controller as follows, using 430.6(A)(1) and Table 430.250 for the full-load currents of the motors:

100-hp, 3-phase FLC

$$124 \text{ A} \times 1.25 = 155.00 \text{ A}$$

1½-hp, 3-phase FLC

$$3 \text{ A} \times 1.25 = \underline{3.75 \text{ A}}$$

$$\text{Total FLC} = 158.75 \text{ A or } 159 \text{ A}$$

Thus, the minimum ampacity for the feeder conductors is 159 amperes. Using the 75°C column from Table 310.15(B)(16), a 2/0 copper conductor is the minimum size required, per 110.14(C)(1)(b).

Supervision of the disconnecting means by a local (protected premises) fire alarm system, central station, proprietary supervising station, or remote supervising station requires a connection to the premises fire alarm system. The connection is generally made through the use of dry contacts in the fire pump controller that are connected to a fire alarm system initiating device circuit. This circuit is programmed to generate a supervisory signal at the fire alarm control unit on loss of voltage to the fire pump controller. A supervisory signal indicates that the suppression system is “off-normal.” Connection of this device must initiate a supervisory signal and may also initiate a trouble signal. For more information on this interface with the fire alarm system, see *NFPA 72®*, *National Fire Alarm and Signaling Code*.

## 695.5 Transformers

Where the service or system voltage is different from the utilization voltage of the fire pump motor, transformer(s) protected by disconnecting means and overcurrent protective devices shall be permitted to be installed between the system supply and the fire pump controller in accordance with 695.5(A) and (B), or with (C). Only transformers covered in 695.5(C) shall be permitted to supply loads not directly associated with the fire pump system.

**(A) Size.** Where a transformer supplies an electric motor driven fire pump, it shall be rated at a minimum of 125 percent of the sum of the fire pump motor(s) and pressure maintenance pump(s) motor loads, and 100 percent of the associated fire pump accessory equipment supplied by the transformer.

**(B) Overcurrent Protection.** The primary overcurrent protective device(s) shall be selected or set to carry indefinitely the sum of the locked-rotor current of the fire pump motor(s) and the pressure maintenance pump motor(s) and the full-load current of the associated fire pump accessory equipment when connected to this power supply. Secondary overcurrent protection shall not be permitted. The requirement to carry the locked-rotor currents indefinitely shall not apply to conductors or devices other than overcurrent devices in the fire pump motor circuit(s).

Dedicated transformer and overcurrent protection sizing can be broken down into three basic requirements. Generally stated, they are as follows:

1. The transformer must be sized to at least 125 percent of the sum of the loads.
2. The transformer primary overcurrent device must be at least a specified minimum size.
3. The transformer secondary must not contain any overcurrent devices whatsoever.

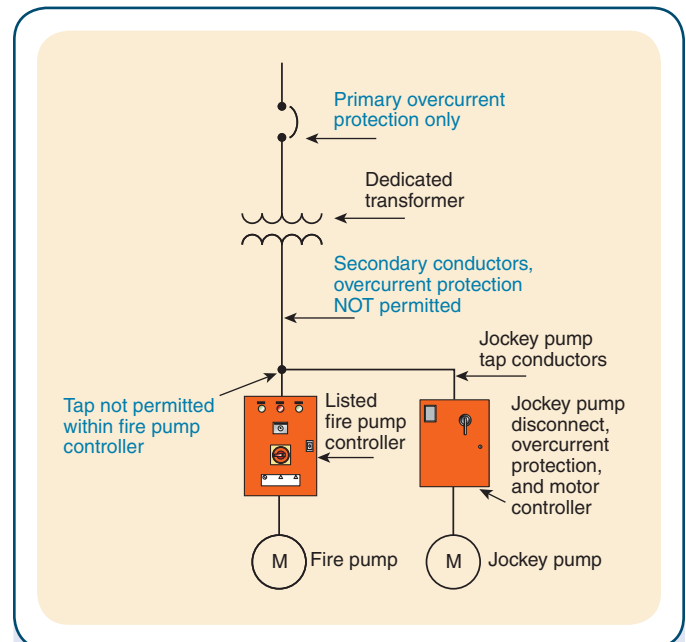

See Exhibit 695.5 for a simple one-line diagram on applying the dedicated fire pump transformer overcurrent protection requirements.

### Calculation Example

A 4160/480-volt, 3-phase, dedicated transformer supplies power to a 100-hp, 460-volt, 3-phase, code letter G fire pump and to a 1½-hp, 460-volt, 3-phase, code letter H jockey pump. Using the requirements of Article 695, determine the sizes of the dedicated transformer and its primary overcurrent protection.

### Solution

**STEP 1.** Determine the minimum standard-size transformer. According to 695.5(A), to determine the minimum current value for use in the 3-phase power calculation, add the full-

**EXHIBIT 695.5** Overcurrent protection for a transformer supplying a fire pump and associated equipment. The device is permitted only in the primary circuit and must be capable of carrying locked-rotor currents of fire pump motor and jockey pump motor indefinitely.

load currents of the fire pump motor(s) and jockey pump motor(s), then increase the total to 125 percent. The result of this calculation provides the minimum kVA rating of a transformer dedicated to a fire pump installation. Any transformer with a kVA rating equal to or greater than the value determined by this calculation is acceptable. First, add the full-load currents of the two motors, using the full-load current (FLC) values from Table 430.250, as follows:

$$\begin{aligned} 100\text{-hp, 3-phase FLC} &= 124 \text{ A} \\ 1\frac{1}{2}\text{-hp, 3-phase FLC} &= 3 \text{ A} \\ \text{Total FLC} &= 127 \text{ A} \end{aligned}$$

Now, increase the sum of the fire pump motor and the jockey pump motor to 125 percent, as follows:

$$127 \text{ A} \times 1.25 = 158.75 \text{ A}$$

Then, size the transformer as follows:

$$\begin{aligned} \text{Transformer kVA} &= \frac{\text{volts} \times \text{amperes} \times \sqrt{3}}{1000} \\ &= \frac{480 \times 158.75 \times \sqrt{3}}{1000} \\ &= 131.98 \text{ kVA} \end{aligned}$$

Thus, the minimum-size transformer permitted by 695.5(A) is 131.98 kVA. The next larger standard-size transformer available is 150 kVA, but any larger size is permitted.

STEP 2. Calculate the minimum-size primary overcurrent protection device permitted for this transformer. According to 695.5(B), the minimum primary overcurrent protection device must allow the transformer secondary to supply the locked-rotor current (LRC) to the fire pump and, in this case, the jockey pump. The locked-rotor current of each motor must be individually calculated if it is not available on the motor nameplate. In this example, however, we are assuming that only the kVA code letters are available. According to 430.7(B) and using the maximum values for the individual code letters per Table 430.7(B), calculate the maximum locked-rotor currents, as follows.

For the 100-hp motor, code letter G:

$$\begin{aligned} \text{LRC} &= \text{motor hp} \times \text{max. code letter value} \\ &\quad \times \frac{1000}{\text{motor voltage} \times 3\text{-phase factor}} \\ &= 100 \text{ hp} \times \frac{6.29 \text{ kVA}}{\text{hp}} \times \frac{1000}{460 \times \sqrt{3}} = 789.49 \text{ A} \end{aligned}$$

For the 1½-hp motor, code letter H (using the same formula):

$$\text{LRC} = 1\frac{1}{2} \text{ hp} \times 7.09 \frac{\text{kVA}}{\text{hp}} \times \frac{1000}{460 \times 3} = 13.35 \text{ A}$$

For the total LRC:

$$\begin{aligned} 100\text{-hp LRC} &= 789.49 \text{ A} \\ 1\frac{1}{2}\text{-hp LRC} &= 13.35 \text{ A} \\ \text{Total LRC} &= 802.84 \text{ A or } 803 \text{ A} \end{aligned}$$

Now, calculate the equivalent LRC on the primary side of the transformer, based on the calculated LRC of the secondary of the transformer, as follows:

$$\begin{aligned} \text{LRC}_{\text{primary}} &= \frac{\text{secondary voltage}}{\text{primary voltage}} \times \text{LRC}_{\text{secondary}} \\ &= \frac{480 \text{ V}}{4160 \text{ V}} \times 803 \text{ A} \\ &= 92.65 \text{ A or } 93 \text{ A} \end{aligned}$$

This value of 93 amperes represents the secondary LRC reflected to the primary side of the transformer. Because this value is the absolute smallest overcurrent protective device permitted, the next larger standard size, according to 240.6, is 100 amperes. Thus, the minimum standard-size overcurrent protective device is 100 amperes.

**Conclusion:** The calculation for a 4160/480-volt, 3-phase transformer supplying a 100-hp fire pump and a 1½-hp jockey pump, both at 460 volts, 3 phase, can be summarized as follows:

1. The smallest standard-size transformer that is permitted is 150 kVA.
2. The smallest standard-size overcurrent protective device permitted on the primary of the transformer is 100 amperes.

3. A secondary overcurrent protective device is not permitted.

**(C) Feeder Source.** Where a feeder source is provided in accordance with 695.3(C), transformers supplying the fire pump system shall be permitted to supply other loads. All other loads shall be calculated in accordance with Article 220, including demand factors as applicable.

**(1) Size.** Transformers shall be rated at a minimum of 125 percent of the sum of the fire pump motor(s) and pressure maintenance pump(s) motor loads, and 100 percent of the remaining load supplied by the transformer.

**(2) Overcurrent Protection.** The transformer size, the feeder size, and the overcurrent protective device(s) shall be coordinated such that overcurrent protection is provided for the transformer in accordance with 450.3 and for the feeder in accordance with 215.3, and such that the overcurrent protective device(s) is selected or set to carry indefinitely the sum of the locked-rotor current of the fire pump motor(s), the pressure maintenance pump motor(s), the full-load current of the associated fire pump accessory equipment, and 100 percent of the remaining loads supplied by the transformer. The requirement to carry the locked-rotor currents indefinitely shall not apply to conductors or devices other than overcurrent devices in the fire pump motor circuit(s).

## 695.6 Power Wiring

Power circuits and wiring methods shall comply with the requirements in 695.6(A) through (J), and as permitted in 230.90(A), Exception No. 4; 230.94, Exception No. 4; 240.13; 230.208; 240.4(A); and 430.31.

### (A) Supply Conductors.

**(1) Services and On-Site Power Production Facilities.** Service conductors and conductors supplied by on-site power production facilities shall be physically routed outside a building(s) and shall be installed as service-entrance conductors in accordance with 230.6, 230.9, and Parts III and IV of Article 230. Where supply conductors cannot be physically routed outside of buildings, the conductors shall be permitted to be routed through the building(s) where installed in accordance with 230.6(1) or (2).

**(2) Feeders.** Fire pump supply conductors on the load side of the final disconnecting means and overcurrent device(s) permitted by 695.4(B), or conductors that connect directly to an on-site standby generator, shall comply with all of the following:

(a) **Independent Routing.** The conductors shall be kept entirely independent of all other wiring.

(b) **Associated Fire Pump Loads.** The conductors shall supply only loads that are directly associated with the fire pump system.

(c) **Protection from Potential Damage.** The conductors shall be protected from potential damage by fire, structural failure, or operational accident.

(d) **Inside of a Building.** Where routed through a building, the conductors shall be installed using one of the following methods:

- (1) Be encased in a minimum 50 mm (2 in.) of concrete
- (2) Be protected by a fire-rated assembly listed to achieve a minimum fire rating of 2 hours and dedicated to the fire pump circuit(s)
- (3) Be a listed electrical circuit protective system with a minimum 2-hour fire rating

Informational Note: UL guide information for electrical circuit protective systems (FHIT) contains information on proper installation requirements to maintain the fire rating.

**Exception to (A)(2)(d):** *The supply conductors located in the electrical equipment room where they originate and in the fire pump room shall not be required to have the minimum 2-hour fire separation or fire resistance rating, unless otherwise required by 700.10(D) of this Code.*

The feeder conductors covered by 695.6(A)(2) are those that are installed from the load side of the supervised disconnecting means permitted by 695.4(B)(1)(a), (b), or (c) to the fire pump controller or combination controller/transfer switch. In addition, conductors directly connected to the output of an on-site standby generator are also subject to the installation requirements of 695.6(A)(2). Unlike service conductors, feeder conductors are installed on the load side of a short-circuit protective device and are not required to be installed on the outside of a building or structure. However, if the feeder conductors are run through a building from the disconnecting means to the fire pump equipment room, they are required to be protected against the effects of a fire to ensure that power to the fire pump is not compromised.

Encasement in 2 in. of concrete, as recognized in 230.6 for service conductors, is one method permitted to isolate and protect feeder conductors. In addition, enclosure of a wiring method within 2-hour fire-resistive building construction and the use of a wiring method listed as an electrical circuit protective system with a minimum 2-hour fire rating are methods permitted for these circuit conductors that do have short-circuit protection. These latter two wiring methods are recognized for protecting conductors against the effects of fire, but they are not recognized as means by which conductors can be considered as being outside a

building or other structure. Therefore, if the installation involves service conductors that have to be run through a building, the only available options, short of installing a supervised disconnecting means, are to install the conductors beneath not less than 2 in. of concrete or to encase the conductors in 2 in. of concrete.

The difference between a 2-hour fire rating of an electrical circuit, such as a conduit with wires, and a 2-hour fire-resistance rating of a structural member, such as a wall, is that at the end of a 2-hour fire test on an electrical conduit with wires, the circuit must function electrically (no short circuits, grounds, or opens are permitted). The circuit and its insulation must be intact and electrically functioning. A wall subjected to a 2-hour fire-resistance test must only prevent a fire from passing through or past the wall, without regard to damage to the wall. All fire ratings and fire-resistance ratings are based on the assumption that the structural supports for the assembly are not impaired by the effects of the fire.

The UL 2004 *Fire Resistance Directory*, Volume 2, describes three categories of products that can be used in the fire protection of electrical circuits for fire pumps: various electrical circuit protective systems (FHIT), electrical circuit protective materials (FHIY), and fire-resistive cables (FHJR). (The four-letter codes in parentheses are the UL product category guide designations.) For information on electrical circuit protective systems, see UL Subject 1724, *Fire Tests for Electrical Circuit Protective Systems*.

## **(B) Conductor Size.**

**(1) Fire Pump Motors and Other Equipment.** Conductors supplying a fire pump motor(s), pressure maintenance pumps, and associated fire pump accessory equipment shall have a rating not less than 125 percent of the sum of the fire pump motor(s) and pressure maintenance motor(s) full-load current(s), and 100 percent of the associated fire pump accessory equipment.

**(2) Fire Pump Motors Only.** Conductors supplying only a fire pump motor shall have a minimum ampacity in accordance with 430.22 and shall comply with the voltage drop requirements in 695.7.

Listed fire pump controller and pump combinations are available in a wye-start, delta-run configuration. From the controller to the motor are six circuit conductors, and when the motor is in the run mode, the conductors that supply each winding are connected in parallel. The minimum conductor ampacity for each of the six leads between the controller and the motor is calculated as shown in the following example.

### Calculation Example

Given a fire pump with a 50-hp, 3-phase motor, 460-volt motor, determine the minimum size for the conductors between the controller and the pump. The pump motor and controller are configured for a wye-start, delta-run operation.

- Fire pump motor nameplate information: 50 hp, 3 phase, 460 volt
- Table 430.250 full-load current for 50-hp motor: 65 amperes
- Section 430.22(A) specifies motor-circuit conductor minimum ampacity based on 125 percent of motor full-load current
- Section 430.22(C) specifies full-load current for conductors on the load side of controller based on 58 percent of motor full-load current

### Solution

STEP 1. Determine minimum conductor ampacity.

$$65 \text{ amperes} \times 0.58 \times 1.25 = 47 \text{ amperes}$$

STEP 2. Determine minimum conductor size.

Assuming 75°C terminations in the controller and conductor insulation type THWN, ampacity selection from Table 310.15(B)16 equals 8 AWG copper circuit conductors (50 amperes)

- There will be six 8 AWG copper conductors between the controller and the motor.
- The combined ampacity of the two circuit conductors connected in parallel to each winding in the run mode is 100 amperes (combined ampacity of two 8 AWG conductors).
- Comparison of controller load-side circuit conductors with minimum ampacity for circuit conductors from the power source to the line side of fire pump controller:

$$65 \text{ amperes} \times 1.25 = 81 \text{ amperes}$$

4 AWG THWN copper circuit conductors

- The minimum size for the conductors as determined here may have to be increased to comply with the mandatory voltage drop performance requirements specified in 695.7.

**(C) Overload Protection.** Power circuits shall not have automatic protection against overloads. Except for protection of transformer primaries provided in 695.5(C)(2), branch-circuit and feeder conductors shall be protected against short circuit only. Where a tap is made to supply a fire pump, the wiring shall be treated as service conductors in accordance with 230.6. The applicable distance and size restrictions in 240.21 shall not apply.

*Exception No. 1: Conductors between storage batteries and the engine shall not require overcurrent protection or disconnecting means.*

*Exception No. 2: For an on-site standby generator(s) rated to produce continuous current in excess of 225 percent of the full-load amperes of the fire pump motor, the conductors between the on-site generator(s) and the combination fire pump transfer switch controller or separately mounted transfer switch shall be installed in accordance with A(695.6)(2). The protection provided shall be in accordance with the short-circuit current rating of the combination fire pump transfer switch controller or separately mounted transfer switch.*

**(D) Pump Wiring.** All wiring from the controllers to the pump motors shall be in rigid metal conduit, intermediate metal conduit, **electrical metallic tubing**, liquidtight flexible metal conduit, or liquidtight flexible nonmetallic conduit Type LFNC-B, listed Type MC cable with an impervious covering, or Type MI cable.

Section 695.6(D) does not apply to light switches, convenience receptacles, telephone outlets, fire detectors, and similar equipment located in the fire pump room.

**(E) Loads Supplied by Controllers and Transfer Switches.** A fire pump controller and fire pump power transfer switch, if provided, shall not serve any load other than the fire pump for which it is intended.

**(F) Mechanical Protection.** All wiring from engine controllers and batteries shall be protected against physical damage and shall be installed in accordance with the controller and engine manufacturer's instructions.

**(G) Ground-Fault Protection of Equipment.** Ground-fault protection of equipment shall not be permitted for fire pumps.

Ground-fault protection of equipment as specified in several sections of the *NEC* is not permitted to be used to protect components of a fire pump installation. (The function of ground-fault protection of equipment protection should not be confused with the function of GFCI protection for personnel.) Although the protection afforded to equipment by this type of ground-fault protection is a mandatory safety requirement in certain circumstances, the need for an uninterrupted source of power takes precedence for fire pump installations. See 240.13(3).

**(H) Listed Electrical Circuit Protective System to Controller Wiring.** Electrical circuit protective system installation shall comply with any restrictions provided in the listing of the electrical circuit protective system used and the following also shall apply:

- (1) A junction box shall be installed ahead of the fire pump controller a minimum of 300 mm (12 in.) beyond the fire-rated wall or floor bounding the fire zone.

The required junction box allows for a transition between solid conductors that are used in some electrical circuit protective systems (Type MI cable, for example) and stranded conductors that are required at the supply terminals of the controller by the controller manufacturer and its listing without having to make the splice in the controller enclosure. In addition, where an electrical circuit protective system employs single conductor cables, such as Type MI cable, the necessity to modify enclosures to prevent inductive heating can result in a compromise of the controller enclosure's resistance to water infiltration.

- (2) Where required by the manufacturer of a listed electrical circuit protective system or by the listing, or as required elsewhere in this *Code*, the raceway between a junction box and the fire pump controller shall be sealed at the junction box end as required and in accordance with the instructions of the manufacturer. [20:9.8.2]

Sealing of the raceway between the junction box and the enclosure may be required by manufacturers of some electrical circuit protective systems. Sealing prevents any conductive material or gases that emanate in the electrical circuit protective system from entering the controller enclosure and compromising the controller operation.

- (3) Standard wiring between the junction box and the controller shall be permitted. [20:9.8.3]

**(I) Junction Boxes.** Where fire pump wiring to or from a fire pump controller is routed through a junction box, the following requirements shall be met:

- (1) The junction box shall be securely mounted. [20:9.7(1)]
- (2) Mounting and installing of a junction box shall not violate the enclosure type rating of the fire pump controller(s). [20:9.7(2)]
- (3) Mounting and installing of a junction box shall not violate the integrity of the fire pump controller(s) and shall not affect the short-circuit rating of the controller(s). [20:9.7(3)]
- (4) As a minimum, a Type 2, drip-proof enclosure (junction box) shall be used where installed in the fire pump

room. The enclosure shall be listed to match the fire pump controller enclosure type rating. [20:9.7(4)]

- (5) Terminals, junction blocks, wire connectors, and splices, where used, shall be listed. [20:9.7(5)]
- (6) A fire pump controller or fire pump power transfer switch, where provided, shall not be used as a junction box to supply other equipment, including a pressure maintenance (jockey) pump(s).

**(J) Raceway Terminations.** Where raceways are terminated at a fire pump controller, the following requirements shall be met: [20:9.9]

- (1) Listed conduit hubs shall be used. [20:9.9.1]
- (2) The type rating of the conduit hub(s) shall be at least equal to that of the fire pump controller. [20:9.9.2]
- (3) The installation instructions of the manufacturer of the fire pump controller shall be followed. [20:9.9.3]
- (4) Alterations to the fire pump controller, other than conduit entry as allowed elsewhere in this *Code*, shall be approved by the authority having jurisdiction. [20:9.9.4]

The requirements of this section are to ensure that the controller enclosure's environmental rating is not compromised by raceway entries into the enclosure. Use of conduit hubs having the same environmental rating as the controller enclosure will minimize the entry of water or other liquids into the enclosure.

## 695.7 Voltage Drop

**(A) Starting.** The voltage at the fire pump controller line terminals shall not drop more than 15 percent below normal (controller-rated voltage) under motor starting conditions.

*Exception: This limitation shall not apply for emergency run mechanical starting. [20:9.4.2]*

**(B) Running.** The voltage at the motor terminals shall not drop more than 5 percent below the voltage rating of the motor when the motor is operating at 115 percent of the full-load current rating of the motor.

## 695.10 Listed Equipment

Diesel engine fire pump controllers, electric fire pump controllers, electric motors, fire pump power transfer switches, foam pump controllers, and limited service controllers shall be listed for fire pump service. [20:9.5.1.1, 10.1.2.1, 12.1.3.1]

This requirement parallels those provisions in NFPA 20, *Standard for the Installation of Stationary Pumps for Fire*

*Protection*, that require components used in fire pump systems to be listed. Prior to being shipped to the installation site, listed fire pump controllers are matched with the listed electric motor(s) they will control to ensure compatibility of the individually listed components. The fire pump controller and transfer switch shown in Exhibit 695.6 is an example of the listed equipment covered in 695.10.

**EXHIBIT 695.6** Listed fire pump controller and power transfer switch.

## 695.12 Equipment Location

**(A) Controllers and Transfer Switches.** Electric motor-driven fire pump controllers and power transfer switches shall be located as close as practicable to, and within sight of, the motors that they control.

**(B) Engine-Drive Controllers.** Engine-drive fire pump controllers shall be located as close as is practical to, and within sight of, the engines that they control.

**(C) Storage Batteries.** Storage batteries for fire pump engine drives shall be supported above the floor, secured against displacement, and located where they are not subject to physical damage, flooding with water, excessive temperature, or excessive vibration.

**(D) Energized Equipment.** All energized equipment parts shall be located at least 300 mm (12 in.) above the floor level.

**(E) Protection Against Pump Water.** Fire pump controller and power transfer switches shall be located or protected so that they are not damaged by water escaping from pumps or pump connections.

**(F) Mounting.** All fire pump control equipment shall be mounted in a substantial manner on noncombustible supporting structures.

The *Code* does not mandate a dedicated room for the fire pump. However, NFPA 20 does specify a suitable space for this equipment that is free from hazards that may impair the operation of the fire pump.

Compliance with the 695.12(A) requirement that fire pump controllers and transfer switches be located “as close as practicable” to the fire pump motor that they control may require that additional space be available to achieve the minimum maintenance working space set forth in 110.26.

Generally, fire pump controllers are housed in substantial enclosures suitable to protect the contents against limited amounts of falling water and dirt. In addition, all energized parts in the enclosure must be mounted at least 12 in. above the floor. Typically, the floor space for this area is equipped with a floor drain.

The requirement of 695.12(F) does not permit fire pump control equipment to be mounted on combustible backboards (such as plywood).

## 695.14 Control Wiring

**(A) Control Circuit Failures.** External control circuits that extend outside the fire pump room shall be arranged so that failure of any external circuit (open or short circuit) shall not prevent the operation of a pump(s) from all other internal or external means. Breakage, disconnecting, shorting of the wires, or loss of power to these circuits could cause continuous running of the fire pump but shall not prevent the controller(s) from starting the fire pump(s) due to causes other than these external control circuits. All control conductors within the fire pump room that are not fault tolerant shall be protected against physical damage. [20:10.5.2.6, 12.5.2.5]

**(B) Sensor Functioning.** No undervoltage, phase-loss, frequency-sensitive, or other sensor(s) shall be installed that automatically or manually prohibits actuation of the motor contactor. [20:10.4.5.6]

*Exception: A phase loss sensor(s) shall be permitted only as a part of a listed fire pump controller.*

**(C) Remote Device(s).** No remote device(s) shall be installed that will prevent automatic operation of the transfer switch. [20:10.8.1.3]

**(D) Engine-Drive Control Wiring.** All wiring between the controller and the diesel engine shall be stranded and sized to continuously carry the charging or control currents

as required by the controller manufacturer. Such wiring shall be protected against physical damage. Controller manufacturer's specifications for distance and wire size shall be followed. [20:12.3.5.1]

**(E) Electric Fire Pump Control Wiring Methods.** All electric motor-driven fire pump control wiring shall be in rigid metal conduit, intermediate metal conduit, liquidtight flexible metal conduit, liquidtight flexible nonmetallic conduit Type B (LFNC-B), listed Type MC cable with an impervious covering, or Type MI cable.

The wiring methods described in 695.14(E) apply only to the control wiring for electric motor-driven fire pumps. They do not apply to the control wiring for engine-driven fire pumps, because there are no similar requirements in NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*.

**(F) Generator Control Wiring Methods.** Control conductors installed between the fire pump power transfer switch and the standby generator supplying the fire pump during normal power loss shall be kept entirely independent of all other wiring. They shall be protected to resist potential damage by fire or structural failure. They shall be permitted

to be routed through a building(s) using one of the following methods:

- (1) Be encased in a minimum of 50 mm (2 in.) of concrete.
- (2) Be protected by a fire-rated assembly listed to achieve a minimum fire rating of 2 hours and dedicated to the fire pump circuits.
- (3) Be a listed electrical circuit protective system with a minimum 2-hour fire rating. The installation shall comply with any restrictions provided in the listing of the electrical circuit protective system used.

Informational Note: UL guide information for electrical circuit protective systems (FHIT) contains information on proper installation requirements to maintain the fire rating.

To ensure operation of an on-site standby generator used to supply an electric fire pump motor, 695.14(F) requires that the conductors be installed using one of the wiring methods that are required for the fire pump power circuit in 695.6(A) (2). Having the power wiring protected against the effects of fire is only one piece of the power reliability consideration. In order for the generator to provide power, it has to receive the necessary signal to start, hence the requirement to provide protection against fire and other physical damage for the control circuit wiring between the fire pump transfer switch/controller and the on-site standby generator.

### I. General

#### 700.1 Scope

The provisions of this article apply to the electrical safety of the installation, operation, and maintenance of emergency systems consisting of circuits and equipment intended to supply, distribute, and control electricity for illumination, power, or both, to required facilities when the normal electrical supply or system is interrupted.

Informational Note No. 1: For further information regarding wiring and installation of emergency systems in health care facilities, see Article 517.

Informational Note No. 2: For further information regarding performance and maintenance of emergency systems in health care facilities, see NFPA 99-2005, *Standard for Health Care Facilities*.

Informational Note No. 3: For specification of locations where emergency lighting is considered essential to life safety, see NFPA 101-2009, *Life Safety Code*.

Informational Note No. 4: For further information regarding performance of emergency and standby power systems, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

Emergency systems are designed and installed to maintain a specific degree of illumination or provide power for essential equipment if the normal power supply fails. Examples of essential equipment include emergency lighting for means of egress and for operating room and life-support equipment in hospitals.

Article 700 applies to the installation of emergency systems that are essential for safety to human life and are legally required by municipal, state, federal, or other codes or by a governmental agency having jurisdiction. Article 700 does not dictate whether emergency systems are required or where emergency or exit lights should be located. These determinations may rely on NFPA 101®, *Life Safety Code*®.

If authorities determine that emergency lighting, including the proper placement of exit signs, is required for safe egress from various classes of buildings or parts of buildings, corridors, passageways, stairways, lobbies, and so on, these must also be sufficiently illuminated.

Article 708, Critical Operations Power Systems (COPS), is intended to power facilities that must be kept continuously operational throughout the duration of an emergency. COPS are generally installed in vital infrastructure facilities — that, if destroyed or incapacitated, would disrupt national security, the economy, public health, or safety — and in areas where enhanced electrical infrastructure for continuity of operation has been deemed necessary by governmental authority.

## 700.2 Definitions

**Emergency Systems.** Those systems legally required and classed as emergency by municipal, state, federal, or other codes, or by any governmental agency having jurisdiction. These systems are intended to automatically supply illumination, power, or both, to designated areas and equipment in the event of failure of the normal supply or in the event of accident to elements of a system intended to supply, distribute, and control power and illumination essential for safety to human life.

Informational Note: Emergency systems are generally installed in places of assembly where artificial illumination is required for safe exiting and for panic control in buildings subject to occupancy by large numbers of persons, such as hotels, theaters, sports arenas, health care facilities, and similar institutions. Emergency systems may also provide power for such functions as ventilation where essential to maintain life, fire detection and alarm systems, elevators, fire pumps, public safety communications systems, industrial processes where current interruption would produce serious life safety or health hazards, and similar functions.

**Relay, Automatic Load Control.** A device used to energize switched or normally-off lighting equipment from an emergency supply in the event of loss of the normal supply, and to de-energize or return the equipment to normal status when the normal supply is restored.

Informational Note: For requirements covering automatic load control relays, see ANSI/UL 924, *Emergency Lighting and Power Equipment*.

Automatic load control relays are permitted to be used in circuits supplied by the emergency system. One use of these devices is in a lighting branch circuit supplied by the emergency system where the load is controlled by an energy management system. The *automatic load control relay* functions to restore the required level of emergency lighting where the lighting has either been dimmed or completely turned off by an energy management system. When the emergency loads are transferred from the normal source to the alternate source, the relay overrides the energy management mode and provides full power to the load. Upon restoration of the normal source, the relay returns the load to the normal operating mode that is controlled by the energy management system. The reference to ANSI/UL 924 provides guidance to users of the *Code* that these devices are suitable for use in circuits supplied by the emergency system.

## 700.3 Tests and Maintenance

**(A) Conduct or Witness Test.** The authority having jurisdiction shall conduct or witness a test of the complete system upon installation and periodically afterward.

**(B) Tested Periodically.** Systems shall be tested periodically on a schedule acceptable to the authority having jurisdiction to ensure the systems are maintained in proper operating condition.

**(C) Battery Systems Maintenance.** Where battery systems or unit equipments are involved, including batteries used for starting, control, or ignition in auxiliary engines, the authority having jurisdiction shall require periodic maintenance.

**(D) Written Record.** A written record shall be kept of such tests and maintenance.

**(E) Testing Under Load.** Means for testing all emergency lighting and power systems during maximum anticipated load conditions shall be provided.

Emergency system testing may be divided into two general categories — acceptance testing and operational testing.

Section 700.3 requires both types of testing as well as written records of each and of maintenance performance.

Acceptance testing is performed after the emergency system has been installed but before the system is used. Acceptance testing ensures that the emergency system meets or exceeds the original installation specification. Portable load banks may be used for acceptance testing of the system to maximum design load.

Operational testing, which is performed during the life of the system, ensures that the emergency system remains functional and that maintenance is performed adequately. One method of operational testing is running the generating system to power the load of the facility. Generally, actual emergency system loads are smaller than the design capacity of the emergency generator system. Actual peak loads of the emergency system should be kept as part of the written record.

Further information on tests and maintenance may be found in *NFPA 72®*, *National Fire Alarm and Signaling Code*; *NFPA 99*, *Standard for Health Care Facilities*; *NFPA 101®*, *Life Safety Code®*; *NFPA 110*, *Standard for Emergency and Standby Power Systems*; and *NFPA 111*, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*.

Informational Note: For testing and maintenance procedures of emergency power supply systems (EPSSs), see *NFPA 110-2010*, *Standard for Emergency and Standby Power Systems*.

## 700.4 Capacity

**(A) Capacity and Rating.** An emergency system shall have adequate capacity and rating for all loads to be operated simultaneously. The emergency system equipment shall be suitable for the maximum available fault current at its terminals.

The emergency system must be designed with adequate capacity and rating to safely carry, at one time, the entire load connected to the emergency system. It must be capable of restarting emergency loads, such as motors, that may have stopped, and it must be suitable for the available fault current. Using devices that limit the available fault current is one method of achieving suitability.

**(B) Selective Load Pickup, Load Shedding, and Peak Load Shaving.** The alternate power source shall be permitted to supply emergency, legally required standby, and optional standby system loads where the source has adequate capacity or where automatic selective load pickup and load shedding is provided as needed to ensure adequate power to (1) the emergency circuits, (2) the legally required standby

circuits, and (3) the optional standby circuits, in that order of priority. The alternate power source shall be permitted to be used for peak load shaving, provided these conditions are met.

Peak load shaving operation shall be permitted for satisfying the test requirement of 700.3(B), provided all other conditions of 700.3 are met.

A portable or temporary alternate source shall be available whenever the emergency generator is out of service for major maintenance or repair.

Section 700.4(B) permits a generator to serve more than one level of emergency, legally required standby, or other operational standby system loads. Section 700.4(B) also permits the use of a generator for peak load shaving, supplying backup power, and other uses. However, assurance is required that priority loads are properly and reliably served. Selective load pickup and load shedding are not required where the generator has the capacity to supply all loads served.

If a generator is used for peak load shaving or in a cogeneration system, major downtime for maintenance of the generator must be anticipated. On the other hand, using the emergency generator on a regular basis for nonemergency loads provides assurance that the emergency generator will supply emergency power when it is needed. The requirement for a portable or temporary alternate source is intended to provide emergency power when the generator set is out of service for a long time. A major maintenance or repair procedure is one that keeps the generator set out of service for more than a few hours.

## 700.5 Transfer Equipment

### General Considerations for Transfer Switches

Automatic transfer switches of double-throw construction are used primarily for emergency and standby power generation systems rated 600 volts or less. These transfer switches do not normally incorporate overcurrent protection and are designed and applied in accordance with the *Code*, particularly Articles 700 and 701. Automatic transfer switches are available in ratings from 30 to 3000 amperes. For reliability, most automatic transfer switches rated above 100 amperes are mechanically held and electrically operated from the power source to which the load is to be transferred. Transfer switches used for emergency and legally required standby systems must be electrically operated and mechanically held.

An automatic transfer switch is usually located in the main or secondary distribution bus that feeds the branch circuits. Because of its location in the system, the capabilities that must be designed into the transfer switch are unique and

extensive compared with the design requirements for other branch-circuit and feeder devices. For example, special consideration should be given to the following characteristics of an automatic transfer:

1. Its ability to close against high inrush currents
2. Its ability to carry full-rated current continuously from normal and emergency sources
3. Its ability to withstand fault currents
4. Its ability to interrupt six times the full-load current

In addition to considering each of the preceding characteristics individually, it is also necessary to consider the effect each has on the others.

In arrangements that provide protection against failure of the utility service, consideration should also be given to the following:

1. An open circuit within the building area on the load side of the incoming service
2. Overload or fault condition
3. Electrical or mechanical failure of the electric power distribution system within the building

It is, therefore, desirable to locate transfer switches close to the load and to keep the operation of the transfer switches independent of overcurrent protection. It is often desirable to use multiple transfer switches of lower current rating located near the load rather than one large transfer switch at the point of incoming service.

### Location of Overcurrent Devices

The location of overcurrent devices for both normal and emergency power is covered by 240.21 and is not affected by the installation of an automatic transfer switch. Transfer switches should be rated for continuous duty and have low contact temperature rise.

### Solid Neutral on Alternating-Current and Direct-Current Systems

If automatic ac-to-ac transfer switches are used, solid neutrals can be used with the grounding connections, as required in 250.24. If multiple grounding creates objectionable ground current, corrective action, as specified in 250.6(B), must be made.

Section 230.95 requires ground-fault protection of equipment. Because the normal source and the emergency source are typically grounded at their locations, the multiple neutral-to-ground connections usually require some additional means or devices to ensure proper ground-fault sensing by the ground-fault protection device. Additional means or devices are generally required because the usual alterations used to stop objectionable current, per 250.6(B), do not apply if the objectionable current is a ground-fault current. [See 250.6(C).] Rather, solutions often include adding an

overlapping neutral transfer pole or conventional fourth pole to the transfer switch. Other solutions include using isolation transformers and special ground-fault circuits or using the service ground to also ground the generator neutral with 3-pole transfer switches.

On ac-to-dc automatic transfer switches, a solid neutral tie between the ac and dc neutrals is not permitted where both sources of supply are exterior distribution systems. Section 250.164, which addresses the location of grounds for dc exterior systems, clearly specifies that the dc system can be grounded only at the supply station. If the dc system is an interior isolated system, such as a storage battery, solid neutral connection between the ac system neutral and the dc source is acceptable.

On an ac-to-dc automatic transfer switch where the neutral must be switched, the size of the neutral switching pole must be considered. A 4-pole, double-throw switch must be used where a 3-phase, 4-wire normal source and a 2-wire dc emergency source are transferred. A 4-pole, double-throw transfer switch is required because the neutral is switched. In this instance, one pole of the dc emergency source carries three times the current of the other poles.

### Close Differential Voltage Supervision of Normal Source

Most often, the normal source is an electric utility company whose power is transmitted many miles to the point of utilization. The automatic transfer switch control panel at the utility company continuously monitors the voltage of all phases. (Because utility frequency is, for all practical purposes, constant, only the voltage needs to be monitored.) For single-phase power systems, the line-to-line voltage is monitored. For 3-phase power systems, all three line-to-line voltages should be monitored to provide full-phase protection.

Monitoring protects against operation at reduced voltage, such as during brownouts, which can damage loads such as motors. Because the voltage sensitivity of loads varies, the pickup (acceptable) voltage setting and dropout (unacceptable) voltage setting of the monitors should be adjustable. The typical range of adjustment for the pickup is 85 to 100 percent of nominal, while the dropout setting, which is a function of the pickup setting, is 75 to 98 percent of the pickup selected. Typical settings for most loads are 95 percent of nominal for pickup and 85 percent of nominal for dropout (90 percent of pickup). Consideration must be given to voltage supervision at a closer differential for many installations where the load circuits are critical to voltage.

Electronic equipment load is frequently voltage critical. Installations that use such equipment include patient care equipment in health care facilities, X-ray equipment, television stations, cable TV centers, microwave communications, telephone communications, computers, computer-operated equipment, computer centers, and similar applications.

Polyphase motors operating at low load have a tendency to single phase, despite the loss of voltage in one phase, leading to burnout of the motor. A close differential of voltage supervision should be applied to automatic transfer switches for motor installations of the polyphase type. Differential voltage relays with a close adjustment of 2 percent for transfer and retransfer values aid in the detection of phase outages and provide protection from single phasing.

#### **Automatic Transfer Switches with Emergency Source on Automatically Started Power Plant**

In installations that require an emergency power source, the normal source is usually a utility power line, and the emergency source is an automatically started engine generator set that starts when the normal source fails. To ensure maximum reliability, a minimum installation should be arranged to do the following:

1. Initiate engine starting of the power plant from a contact on the automatic transfer switch control panel.
2. Sustain connection of load circuits to the normal source during the starting period to provide utilization of any existing service from the normal source.
3. Measure output voltage and frequency of emergency source through the use of a voltage-frequency-sensitive monitor and effect transfer of the load circuits to the power plant only when both voltage and frequency of the power plant are approximately normal. Sensing of the emergency source need only be single phase, because most applications involve an on-site engine generator with a relatively short line run to the automatic transfer switch. In addition to monitoring voltage, the emergency source's frequency should be monitored. Unlike the utility power, the engine generator frequency can vary during start-up. Frequency monitoring avoids overloading the engine generator while it is starting and can thus prevent stalling the engine. Combined frequency and voltage monitoring prevents loads from being transferred to an engine generator set with an unacceptable output.
4. Provide visual signal and auxiliary contact for remote indication when the power plant is feeding the load.

#### **Time-Delay Devices on Automatic Transfer Switches**

Time-delay controls are essential to the operation of the automatic transfer switch. To avoid unnecessary starting and transfer to the alternate supply, a nominal 1-second time delay, adjustable up to 6 seconds, can override momentary interruptions and temporary reductions in normal source voltage but still allow starting and transfer if the reduction or outage is sustained. Local electric utilities can provide circuit protection schemes and timing information. Because momentary outages may last 2 seconds, nominal, a correctly

set time delay should prevent the transfer switch from operating (and prevent generator starting) during utility automatic circuit protection operation. However, the time delay should be set fast enough to effectively operate the transfer switch and provide backup power for long-term outages.

The advantages of a time delay are realized in all types of automatic transfer installations. In standby plant installations, the reduced number of false starts is especially important to minimize wear on the starting gear, battery, and associated equipment. This delay is generally set at 1 second but may be set higher if reclosers or circuit breakers on the utility power lines take longer to operate or if momentary power dips exceed 1 second. If longer delay settings are used, care must be taken to ensure that sufficient time remains to meet 10-second power restoration requirements. The authority having jurisdiction may determine that a longer-term power failure does not occur until the utility automatic protective devices fail to restore power to the facility. For example, the 10-second power restoration requirements would become effective after the 2-second, nominal, recloser or circuit breaker cycle.

Once the load is transferred to the alternate source, another timer delays retransfer to the normal source until that source has time to stabilize. See the commentary following the exception to 700.16. This timer is required by 700.12(B) (1) and is controlled by the preferred source voltage monitors. The timer is adjustable from 0 to 30 minutes and is normally set at 30 minutes. Another important function of this retransfer timer is to allow an engine generator to operate under load for a preselected minimum time to ensure continued good performance of the set and its starting system. This delay should be automatically nullified if the alternate source fails and the normal source is available, as determined by the voltage monitors.

Engine generator manufacturers often recommend a cool-down period for their sets that allows them to run unloaded after the load is retransferred to the normal source. A third time delay, usually 5 minutes, is provided for this purpose. Running an unloaded engine for more than 5 minutes is neither necessary nor recommended because it can cause deterioration in engine performance.

If more than one automatic transfer switch is connected to the same engine generator, it is sometimes recommended that transfer of the loads be purposely sequenced to the alternate source. Using such a sequencing scheme can reduce starting kVA capacity requirements of the generator. A fourth timer, adjustable from 0 to 5 minutes, will delay transfer to the emergency supply source for this and other, similar requirements.

**(A) General.** Transfer equipment, including automatic transfer switches, shall be automatic, identified for emergency use, and approved by the authority having jurisdiction.

tion. Transfer equipment shall be designed and installed to prevent the inadvertent interconnection of normal and emergency sources of supply in any operation of the transfer equipment. Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.

Section 700.5(A) allows parallel operation of the generation equipment with the normal source as long as the requirements of Article 705 are met. Traditional automatic transfer switches are not designed to permit parallel operation of generation equipment and the normal source. Therefore, traditional automatic transfer switches need not comply with Article 705. However, certain automatic transfer switch configurations are intentionally designed to briefly (a few cycles) parallel the generation equipment with the normal source upon load transfer from generator to normal source. This load transfer can occur with minimal disturbance or effect on the load. Transfer switches that employ this type of paralleling must comply with Article 705.

If continuous parallel operation of generation equipment and the source is desired, paralleling switchgear or paralleling equipment with appropriate protection is required. (See Article 705.)

**(B) Bypass Isolation Switches.** Means shall be permitted to bypass and isolate the transfer equipment. Where bypass isolation switches are used, inadvertent parallel operation shall be avoided.

**(C) Automatic Transfer Switches.** Automatic transfer switches shall be electrically operated and mechanically held. Automatic transfer switches, rated 600 VAC and below, shall be listed for emergency system use.

Section 700.5(C) ensures that relay contacts are mechanically held in the event of coil failure. In coordination with NFPA 110, *Standard for Emergency and Standby Power Systems*, this section requires transfer switches rated 600 volts ac and below to be listed for emergency systems use.

When emergency systems are tested, both the normal and the emergency system are energized. If the two sources are not synchronized, as much as twice the rated voltage may exist across the transfer switch contacts. Some listed transfer switches are designed and tested to be suitable for switching between out-of-phase power sources. Other protection methods may be employed, such as a mechanical interlock that prevents inadvertent interconnection, or an electronic method that prevents both systems from being interconnected. A typical emergency system transfer switch is shown in Exhibit 700.1.

**EXHIBIT 700.1** An emergency system transfer switch. (Courtesy of the International Association of Electrical Inspectors)

**(D) Use.** Transfer equipment shall supply only emergency loads.

Although the alternate power source for the emergency system is permitted to supply emergency loads as well as other loads, 700.5(D) limits the transfer switch to emergency loads, that is, loads classified as emergency in accordance with 700.1. Other loads, such as legally required standby loads or optional standby loads (covered by Articles 701 and 702), are not permitted to be supplied from the emergency system transfer switch. Where a single generator is used to supply both emergency and nonemergency loads, multiple transfer switches are required.

## 700.6 Signals

Audible and visual signal devices shall be provided, where practicable, for the purpose described in 700.6(A) through (D).

**(A) Derangement.** To indicate derangement of the emergency source.

**(B) Carrying Load.** To indicate that the battery is carrying load.

**(C) Not Functioning.** To indicate that the battery charger is not functioning.

The major causes of emergency equipment failure are improper testing or lack of testing, inadequate maintenance, and the failure of attendants to see the signals that indicate

malfunctioning battery or battery-charging equipment. One way to minimize equipment failure is to install signal devices that annunciate trouble where attendants or other personnel familiar with the operation of the emergency equipment can see or hear them. In theaters, assembly halls, or similar locations, audible signal bells or horns that annunciate the functions specified in 700.6 should be located where their sounding will not cause panic.

Battery-operated unit equipment generally has a test switch that simulates failure of the normal system, and an indicating light that glows brightly while charging and dims when ready. Transparent cases for lead-acid batteries allow easy viewing of electrolyte levels.

A storage battery system is normally capable of delivering 12, 24, 32, or 120 volts and consists of monitoring and distribution cabinets and a console with battery and charger. A storage battery system generally includes audible, visual, and remote signal devices and a test switch, and it may include a trouble bell and silence switch.

**(D) Ground Fault.** To indicate a ground fault in solidly grounded wye emergency systems of more than 150 volts to ground and circuit-protective devices rated 1000 amperes or more. The sensor for the ground-fault signal devices shall be located at, or ahead of, the main system disconnecting means for the emergency source, and the maximum setting of the signal devices shall be for a ground-fault current of 1200 amperes. Instructions on the course of action to be taken in event of indicated ground fault shall be located at or near the sensor location.

Informational Note: For signals for generator sets, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

Although 700.26 indicates that ground-fault protection of equipment is not required on the alternate source for emergency systems, ground faults can occur on such systems, and they can result in equipment burndown. Because of the emergency nature of such systems, automatic disconnect in the event of a ground fault is inappropriate. Detection of such a fault, however, is desirable so that the condition can be corrected.

## 700.7 Signs

**(A) Emergency Sources.** A sign shall be placed at the service-entrance equipment, indicating type and location of on-site emergency power sources.

A sign is required at the service equipment that indicates the type and location of an emergency source. See Exhibit 700.2.

**EXHIBIT 700.2** An example of the sign required by 700.7(B).

*Exception: A sign shall not be required for individual unit equipment as specified in 700.12(F).*

**(B) Grounding.** Where removal of a grounding or bonding connection in normal power source equipment interrupts the grounding electrode conductor connection to the alternate power source(s) grounded conductor, a warning sign shall be installed at the normal power source equipment stating:

**WARNING**  
**SHOCK HAZARD EXISTS IF GROUNDING**  
**ELECTRODE CONDUCTOR OR BONDING JUMPER**  
**CONNECTION IN THIS EQUIPMENT IS REMOVED**  
**WHILE ALTERNATE SOURCE(S) IS ENERGIZED.**

Section 700.7(B) requires a sign at the service equipment or other normal power source supply to warn personnel of the potential shock hazard if a grounding or bonding connection is interrupted while the alternate source is energized. Emergency and standby systems that have a solid (unswitched) neutral in the transfer equipment (non-separately derived system) rely on the grounding and bonding connections in the normal source supply equipment to ensure that the ground-fault current path is completed from a ground fault to the alternate source. If a main or system bonding jumper is removed (for example, to perform testing on GFPE systems) an electrician or other service personnel could inadvertently become part of the current path if a ground fault occurs while the alternate source is supplying power to loads. This of course poses a significant shock hazard to personnel who may not be aware of the grounding and bonding configuration for the alternate source. The warning sign alerts personnel to this condition so that proper safety procedures can be implemented while

the normal supply equipment is being serviced, tested, or maintained.

## II. Circuit Wiring

### 700.10 Wiring, Emergency System

**(A) Identification.** All boxes and enclosures (including transfer switches, generators, and power panels) for emergency circuits shall be permanently marked so they will be readily identified as a component of an emergency circuit or system.

The marking required by 700.10(A) can be by color code, the words “emergency system,” or any other type of identification that identifies the box or enclosure as a component of the emergency system.

**(B) Wiring.** Wiring of two or more emergency circuits supplied from the same source shall be permitted in the same raceway, cable, box, or cabinet. Wiring from an emergency source or emergency source distribution overcurrent protection to emergency loads shall be kept entirely independent of all other wiring and equipment, unless otherwise permitted in (1) through (5):

- (1) Wiring from the normal power source located in transfer equipment enclosures
- (2) Wiring supplied from two sources in exit or emergency luminaires
- (3) Wiring from two sources in a listed load control relay supplying exit or emergency luminaires, or in a common junction box, attached to exit or emergency luminaires
- (4) Wiring within a common junction box attached to unit equipment, containing only the branch circuit supplying the unit equipment and the emergency circuit supplied by the unit equipment

Where an alternate power source supplies a switchboard from a single feeder or feeders in parallel, that switchboard may further distribute and provide power for the emergency, legally required, and optional standby systems.

Switchboards provide the physical separation requirements of both system and wiring from a common power source. This physical separation cannot occur within a panelboard enclosure because of its open design. Individual overcurrent sections can supply emergency, legally required, and optional standby transfer switches.

Where generators operate in parallel, frequency and voltage are synchronized and supply a common bus array. From this bus, emergency, legally required, and optional standby transfer switches can be supplied.

Emergency circuit wiring is not permitted to enter the same raceway, cable, box, or cabinet as the regular or normal wiring of the building. Wiring for the emergency circuits must be completely independent of all other wiring and equipment. This practice ensures that any fault on the normal wiring circuits will not affect the performance of the emergency wiring or equipment.

To effect an immediate transfer from one system to the other, both the normal source and the emergency source must be present within a transfer switch enclosure per 700.10(B)(1). Sections 700.10(B)(2) and (B)(3) permit the use of two-lamp exit or two-lamp emergency fixtures, where one lamp is connected to the normal supply and one lamp is connected to the alternate supply. Both lamps may be illuminated as part of the regular lighting operation.

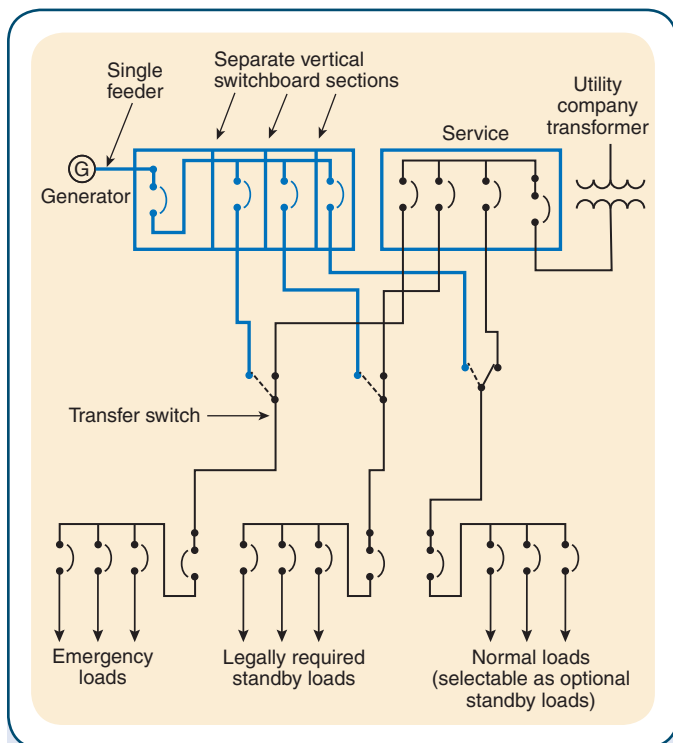

Section 700.10 requires separation of the wiring of the emergency system from the wiring of the normal system, legally required standby systems, and optional standby systems. The supply tap box on generators equipped with disconnects with or without overcurrent protection is not generally designed or manufactured for the installation of multiple transfer switches to serve separate circuits, for emergency systems, fire pump loads, legally required standby systems, and optional standby systems. In addition, large systems may employ multiple generators. The text now clarifies that any combination of these systems may be supplied from a single feeder or multiple feeders or from separate vertical sections of a switchboard that are supplied by either a common bus or individually. See Exhibits 700.3 through 700.5.

Wiring on the load side of a transfer switch serves as both the emergency circuit wiring and the normal circuit wiring. It is not intended that two sets of wiring supply emergency loads from the transfer switch to the emergency load distribution panel, as shown in Exhibits 700.4 and 700.5, or from these emergency distribution panels to the emergency loads.

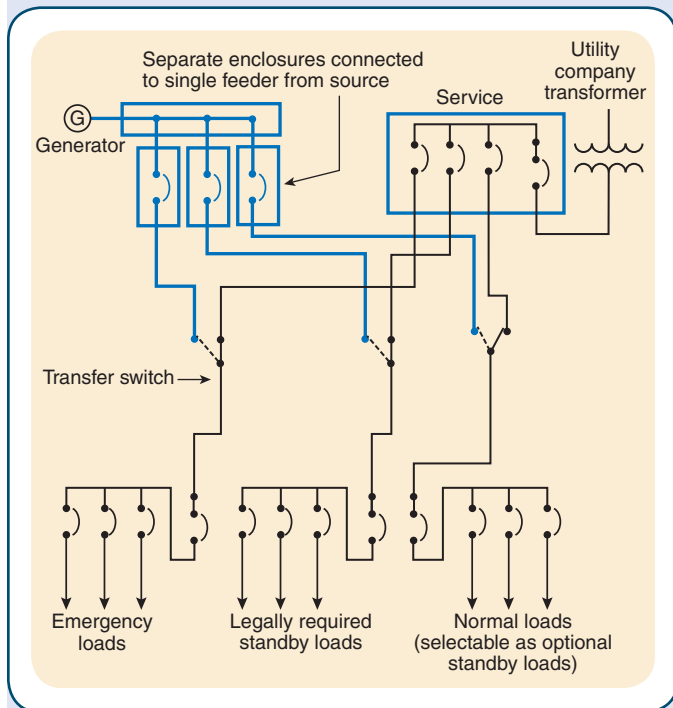

- (5) Wiring from an emergency source to supply any combination of emergency, legally required, or optional loads in accordance with (a), (b), (c), and (d):
  - a. From separate vertical switchboard sections, with or without a common bus, or from individual disconnects mounted in separate enclosures.
  - b. The common bus or separate sections of the switchboard or the individual enclosures shall be permitted to be supplied by single or multiple feeders without overcurrent protection at the source.

*Exception to (5)(b): Overcurrent protection shall be permitted at the source or for the equipment, provided the overcurrent protection complies with the requirements of 700.27.*

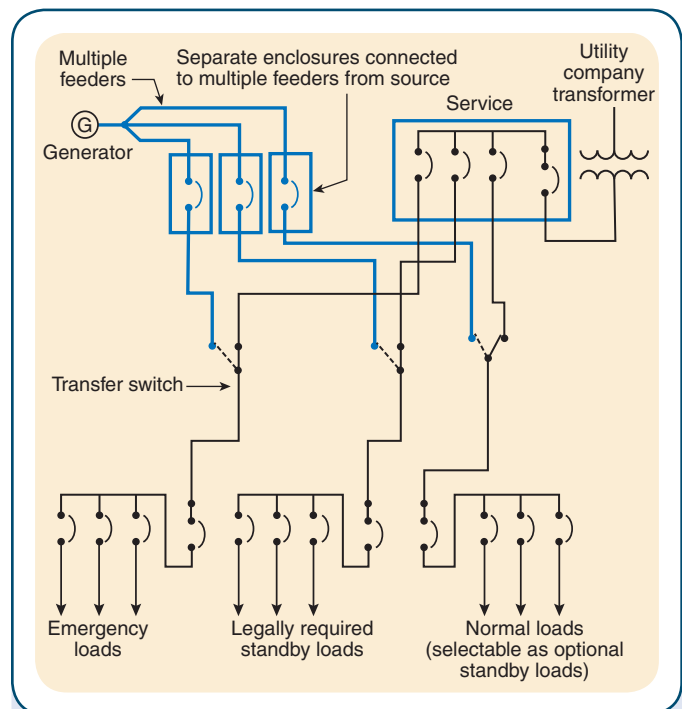

**EXHIBIT 700.3** Illustration of a single feeder from the generator to the switchboard. The feeder supplies separate vertical sections of the switchboard to provide separation for the different systems.

**EXHIBIT 700.4** Illustration of a single feeder that supplies multiple transfer switches.

**EXHIBIT 700.5** Illustration of a generator that supplies multiple feeders at its terminals.

- c. Legally required and optional standby circuits shall not originate from the same vertical switchboard section, panelboard enclosure, or individual disconnect enclosure as emergency circuits.
- d. It shall be permissible to utilize single or multiple feeders to supply distribution equipment between an emergency source and the point where the combination of emergency, legally required, or optional loads are separated.

Section 700.10(B)(5)(d) permits a single feeder to supply combinations of emergency, legally required standby, and optional loads. The use of a single feeder is permitted to be installed between the alternate source and the point in the distribution system at which the physical separation of the emergency, legally required standby, and optional standby system conductors occurs, such as at a switchboard, transfer switch, or other distribution equipment. Many large campus facilities with multiple buildings, such as medical centers, colleges or universities, prisons, and shopping malls, rely on central generation of emergency power.

**(C) Wiring Design and Location.** Emergency wiring circuits shall be designed and located so as to minimize the hazards that might cause failure due to flooding, fire, icing, vandalism, and other adverse conditions.

The same requirement applies to sources of power covered in 700.12.

**(D) Fire Protection.** Emergency systems shall meet the additional requirements in (D)(1) through (D)(3) in assembly occupancies for not less than 1000 persons or in buildings above 23 m (75 ft) in height with any of the following occupancy classes: assembly, educational, residential, detention and correctional, business, and mercantile.

Informational Note: For the definition of *Occupancy Classification*, see Section 6.1 of NFPA 101-2009, *Life Safety Code*.

**(1) Feeder-Circuit Wiring.** Feeder-circuit wiring shall meet one of the following conditions:

- (1) Be installed in spaces or areas that are fully protected by an approved automatic fire suppression system
- (2) Be a listed electrical circuit protective system with a minimum 2-hour fire rating

Informational Note: UL guide information for electrical circuit protective systems (FHIT) contains information on proper installation requirements to maintain the fire rating.

- (3) Be protected by a listed thermal barrier system for electrical system components with a minimum 2-hour fire rating
- (4) Be protected by a listed fire-rated assembly that has a minimum fire rating of 2 hours and contains only emergency wiring circuits.

Where emergency system wiring is installed in a listed fire-rated assembly, no other wiring is permitted within the fire-rated assembly. If a fire-rated assembly is needed for normal circuits, it must be a separate fire-rated assembly from the one used for the emergency system.

- (5) Be encased in a minimum of 50 mm (2 in.) of concrete

Section 700.10(D)(1) requires fire protection of emergency feeder conductors through the use of an approved automatic fire suppression system; a minimum 2-hour fire rating provided by a listed electrical circuit protective system; a listed thermal barrier system for electrical system components; a listed fire-rated assembly; or be encased in 2 in. of concrete.

It is important to understand the difference between a 2-hour fire rating of an electrical circuit, such as a conduit with wires, and a 2-hour fire resistance rating of a structural member, such as a wall. At the end of a 2-hour fire test on an electrical conduit with wires, the circuit must function electrically; no short circuits, grounds, or opens are permitted.

The circuit and its insulation must be intact and electrically functioning. A wall subjected to a 2-hour fire resistance test must only prevent a fire from passing through or past the wall, without regard to damage to the wall. All fire ratings and fire resistance ratings are based on the assumption that the structural supports for the assembly are not impaired by the effects of the fire.

The *UL Fire Resistance Directory* describes various categories of products that can be used in the fire protection of electrical circuits, including electrical circuit protective systems (FHIT). See the informational note following 700.10(D)(1)(2) for more information. Note that the four-letter code in parentheses, FHIT, is the UL product category guide designation. For information on electrical circuit protective systems, see UL 1724, *Outline of Investigation for Fire Tests for Electrical Circuit Protective Systems*.

**(2) Feeder-Circuit Equipment.** Equipment for feeder circuits (including transfer switches, transformers, and panelboards) shall be located either in spaces fully protected by approved automatic fire suppression systems (including sprinklers, carbon dioxide systems) or in spaces with a 2-hour fire resistance rating.

The proper operation of emergency electrical systems is critical for densely populated occupancies and for high-rise occupancies. Therefore, fire protection requirements for both emergency system feeder circuits and equipment ensure the integrity as well as the performance of the emergency electrical system. If feeders and equipment are located in buildings that are fully protected by an approved fire suppression system, no further fire protection techniques are generally required.

Sprinkler systems are the most common fire suppression systems, and they are covered in NFPA 13, *Standard for the Installation of Sprinkler Systems*. Buildings that are fully protected by automatic sprinkler systems meet the requirements of 700.10(D). Additional fire suppression systems are included in the following standards:

1. NFPA 11, *Standard for Low-, Medium-, and High-Expansion Foam*
2. NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*
3. NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*
4. NFPA 15, *Standard for Water Spray Fixed Systems for Fire Protection*
5. NFPA 17, *Standard for Dry Chemical Extinguishing Systems*

#### 6. NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*

If feeders and equipment are not located in buildings that are fully protected by an approved fire suppression system, other methods and protection techniques are available to comply with the fire protection requirements of 700.10(D)(2). These additional fire protection techniques include the following methods.

**Listed Electrical Circuit Protective Systems.** These systems are described in the UL *Building Materials Directory*. The four-letter code (shown in parentheses) following each category heading in the directory is the UL product category guide designation. Examples of these systems include electrical circuit protective systems (FHIT), electrical circuit protective materials (FHIY), and fire-resistive cables (FHJR).

**Listed Thermal Barrier Systems.** These systems are described in the UL *Building Materials Directory* as thermal barrier systems (XCLF). Examples of the thermal barrier protection technique include batts and blankets (XCLR), packing material (XCMD), and preformed mineral and fiber units (XCMK) wrapped or otherwise formed over the conduit to achieve a predetermined fire rating.

**Fire-Rated Assembly.** These systems are described in the UL *Fire Resistance Directory*, Volumes 1 and 2. The assemblies found in Volume 1 include hourly ratings for beams, floors, roofs, columns, and walls and partitions. Volume 2 of the directory includes hourly ratings for joint systems and through-penetration firestop systems. All fire ratings and fire resistance ratings are based on the assumption that the structural supports for the assembly are not impaired by the fire.

**Embedded in Concrete.** Embedding a conduit in concrete is most effective when implemented during original construction. This method has been successful for many years in protecting premises from faults in service conductors. According to 230.6, conductors embedded in not less than 2 in. of concrete are considered to be outside the building.

**Cables Listed to Maintain Circuit Integrity.** Circuit integrity cables are classified by the UL *Building Materials Directory* under the existing product category of fire-resistive cables (FHJR).

It is important to understand the difference between a 2-hour fire rating of an electrical cable and a 2-hour fire resistance rating of a structural member, such as a wall. At the end of a 2-hour fire test on an electrical cable, the circuit and its insulation must be intact and function electrically; no short circuits, grounds, or opens are permitted. The cable must be intact and electrically functioning. A wall subjected to a 2-hour fire resistance test must only prevent a fire from

passing through or past the wall, without regard to damage to the wall.

•  
(3) **Generator Control Wiring.** Control conductors installed between the transfer equipment and the emergency generator shall be kept entirely independent of all other wiring and shall meet the conditions of 700.10(D)(1).

Starting the generator is a critical element to restoring power to emergency loads when the normal source is lost. To help ensure this, separation from other circuit conductors and fire protection are two techniques required for the protection of control circuit conductors installed between the automatic transfer equipment and the alternate source.

## III. Sources of Power

### General Requirements for Emergency Lighting Systems

At least two sources of power must be provided — one normal supply and one or more emergency systems described in 700.12. The sources may be (1) two services — one normal supply and one emergency supply (preferably from separate utility stations), (2) one normal service and a storage battery (or unit equipment) system, or (3) one normal service and a generator set. (See Exhibits 700.6 and 700.7.)

A transfer means (or throw-over switch) must be provided to energize the emergency equipment from the alternate supply when the normal source of supply is interrupted. If a separate service is used, both may operate normally, but equipment for emergency lighting and power must be arranged to be energized from either service.

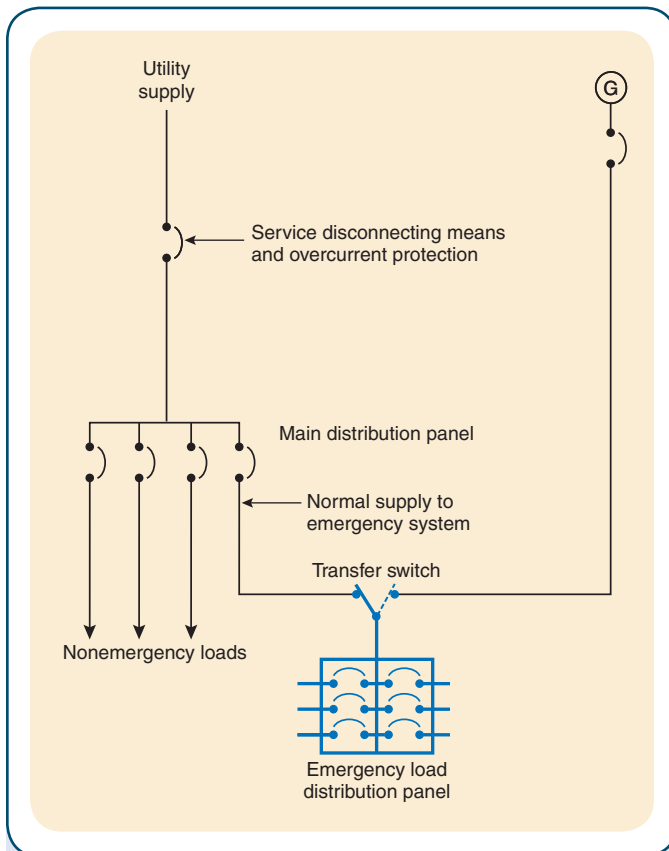

If the alternate or emergency source of supply is a storage battery or generator set, the single emergency system is usually operated on the normal service, and the battery (or batteries) or generator operates only if the normal service fails. A generator may be used, however, for peak load shaving and the like in accordance with 700.4.

Two or more separate and complete systems may provide power for emergency lighting, but means must be provided for energizing one system if the other one fails.

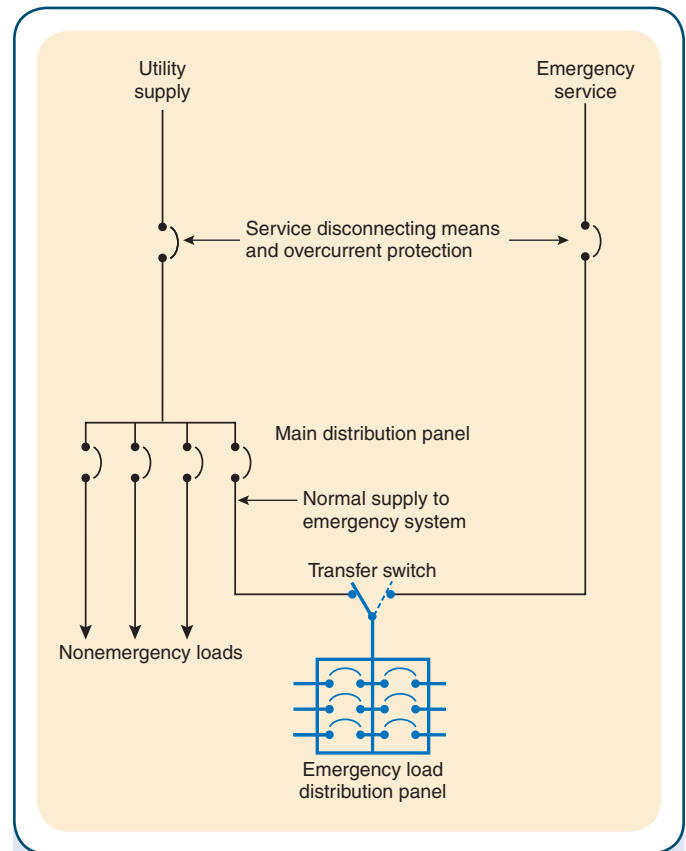

Note that requirements for disconnecting means and overcurrent protection (see Exhibits 700.6 and 700.7) are to be provided for emergency systems as required by Article 230.

## 700.12 General Requirements

Current supply shall be such that, in the event of failure of the normal supply to, or within, the building or group of

**EXHIBIT 700.6** Emergency load arranged to be supplied from a generator, as permitted by 700.12(B).

**EXHIBIT 700.7** Emergency load arranged to be supplied from two widely separated services, as permitted by 700.12(D). When one service fails, the emergency load is transferred to the other service.

buildings concerned, emergency lighting, emergency power, or both shall be available within the time required for the application but not to exceed 10 seconds. The supply system for emergency purposes, in addition to the normal services to the building and meeting the general requirements of this section, shall be one or more of the types of systems described in 700.12(A) through (E). Unit equipment in accordance with 700.12(F) shall satisfy the applicable requirements of this article.

In selecting an emergency source of power, consideration shall be given to the occupancy and the type of service to be rendered, whether of minimum duration, as for evacuation of a theater, or longer duration, as for supplying emergency power and lighting due to an indefinite period of current failure from trouble either inside or outside the building.

Equipment shall be designed and located so as to minimize the hazards that might cause complete failure due to flooding, fires, icing, and vandalism.

Emergency system equipment, including generators, is permitted to be installed indoors or outdoors. Section 700.12

requires that the design and the selection of location consider hazards that could impair reliability. See Exhibit 700.8.

Equipment for sources of power as described in 700.12(A) through (E) where located within assembly occupancies for greater than 1000 persons or in buildings above 23 m (75 ft) in height with any of the following occupancy classes — assembly, educational, residential, detention and correctional, business, and mercantile — shall be installed either in spaces fully protected by approved automatic fire suppression systems (sprinklers, carbon dioxide systems, and so forth) or in spaces with a 1-hour fire rating.

Informational Note No. 1: For the definition of *Occupancy Classification*, see Section 6.1 of NFPA 101-2009, *Life Safety Code*.

Informational Note No. 2: Assignment of degree of reliability of the recognized emergency supply system depends on the careful evaluation of the variables at each particular installation. For further information, see ANSI/IEEE 493-2007, *Recommended Practice for the Design of Reliable Industrial and Commercial Power Systems*.

**EXHIBIT 700.8** Alternate source of power in a heated and secure enclosure that is located in an area not subject to flooding. (Courtesy of the International Association of Electrical Inspectors)

**(A) Storage Battery.** Storage batteries used as a source of power for emergency systems shall be of suitable rating and capacity to supply and maintain the total load for a minimum period of 1½ hours, without the voltage applied to the load falling below 87½ percent of normal.

Batteries, whether of the acid or alkali type, shall be designed and constructed to meet the requirements of emergency service and shall be compatible with the charger for that particular installation.

For a sealed battery, the container shall not be required to be transparent. However, for the lead acid battery that requires water additions, transparent or translucent jars shall be furnished. Automotive-type batteries shall not be used.

An automatic battery charging means shall be provided.

#### **(B) Generator Set.**

**(1) Prime Mover-Driven.** For a generator set driven by a prime mover acceptable to the authority having jurisdiction and sized in accordance with 700.4, means shall be provided for automatically starting the prime mover on failure of the normal service and for automatic transfer and operation of all required electrical circuits. A time-delay feature permitting a 15-minute setting shall be provided to avoid retransfer in case of short-time reestablishment of the normal source.

**(2) Internal Combustion Engines as Prime Movers.** Where internal combustion engines are used as the prime mover, an on-site fuel supply shall be provided with an on-premises fuel supply sufficient for not less than 2 hours' full-demand operation of the system. Where power is needed for the operation of the fuel transfer pumps to deliver fuel to a

generator set day tank, this pump shall be connected to the emergency power system.

Engine-driven generators that require a fuel pump may not start or continue operating if the fuel pump is not operating. The last sentence of 700.12(B)(2) ensures that fuel transfer pumps have power when needed.

**(3) Dual Supplies.** Prime movers shall not be solely dependent on a public utility gas system for their fuel supply or municipal water supply for their cooling systems. Means shall be provided for automatically transferring from one fuel supply to another where dual fuel supplies are used.

*Exception: Where acceptable to the authority having jurisdiction, the use of other than on-site fuels shall be permitted where there is a low probability of a simultaneous failure of both the off-site fuel delivery system and power from the outside electrical utility company.*

**(4) Battery Power and Dampers.** Where a storage battery is used for control or signal power or as the means of starting the prime mover, it shall be suitable for the purpose and shall be equipped with an automatic charging means independent of the generator set. Where the battery charger is required for the operation of the generator set, it shall be connected to the emergency system. Where power is required for the operation of dampers used to ventilate the generator set, the dampers shall be connected to the emergency system.

Engine-driven generators that are not equipped with an alternator to provide battery charging require a separate battery-charging system. Failure of the power supply to a battery-charging system or failure of the battery-charging system itself could render the engine-driven generator inoperable. Connecting the charger to the emergency system ensures that it always has power.

Where ventilation dampers require electrical power in order to operate, 700.12(B)(4) also requires them to be powered by the emergency power source to ensure operation when the engine-driven generator operates. These additional loads require the system designer to ensure that the engine-driven generator is of adequate capacity in accordance with 700.4(A).

**(5) Auxiliary Power Supply.** Generator sets that require more than 10 seconds to develop power shall be permitted if an auxiliary power supply energizes the emergency system until the generator can pick up the load.

**(6) Outdoor Generator Sets.** Where an outdoor housed generator set is equipped with a readily accessible disconnecting means located within sight of the building or structure supplied, an additional disconnecting means shall not be required where ungrounded conductors serve or pass through the building or structure. The disconnecting means shall meet the requirements of 225.36.

Section 700.12(B)(6) clarifies the requirements for the disconnecting means for an outdoor generator set. The disconnecting means on the generator can be used as the disconnecting means required in 225.31, provided the disconnecting means is readily accessible and is within sight of the building. The disconnecting means must also be suitable for use as service equipment in accordance with 225.36. See the definitions of the terms *accessible*, *readily*, and *in sight from* in Article 100.

*Exception: For installations under single management, where conditions of maintenance and supervision ensure that only qualified persons will monitor and service the installation and where documented safe switching procedures are established and maintained for disconnection, the generator set disconnecting means shall not be required to be located within sight of the building or structure served.*

The exception to 700.12(B)(6) correlates with Exception No. 1 following 225.32. This provision applies to a disconnecting means associated with an outdoor generator supplying emergency loads in a building or structure. The circuit between the generator and the building or structure is most typically a feeder. Therefore, the general requirements for outdoor feeders contained in Article 225 must be followed, including those covering disconnecting means for outdoor branch circuits and feeders. The specific modification in 700.12(B)(6) permits the feeder disconnecting means to be located at the generator location provided the disconnecting means is within sight and readily accessible from the building being supplied.

The exception to 700.12(B)(6) exempts the generator disconnecting means from the “within sight of” requirement specified in 700.12(B)(6). The exception provides the condition upon which the installation can be operated and maintained safely (i.e., the use of qualified persons for the maintenance and supervision of installation and documented safe switching procedures are established and maintained) and this is considered to be equally as safe as having the disconnecting means within sight of the building or structure being supplied.

**(C) Uninterruptible Power Supplies.** Uninterruptible power supplies used to provide power for emergency systems shall comply with the applicable provisions of 700.12(A) and (B).

**(D) Separate Service.** Where approved by the authority having jurisdiction as suitable for use as an emergency source of power, an additional service shall be permitted. This service shall be in accordance with the applicable provisions of Article 230 and the following additional requirements:

- (1) Separate service drop or service lateral
- (2) Service conductors sufficiently remote electrically and physically from any other service conductors to minimize the possibility of simultaneous interruption of supply

**(E) Fuel Cell System.** Fuel cell systems used as a source of power for emergency systems shall be of suitable rating and capacity to supply and maintain the total load for not less than 2 hours of full-demand operation.

Installation of a fuel cell system shall meet the requirements of Parts II through VIII of Article 692.

Where a single fuel cell system serves as the normal supply for the building or group of buildings concerned, it shall not serve as the sole source of power for the emergency standby system.

When designing emergency systems, whether for lighting or power, or both, the type of source that is needed must be considered.

Supply systems for emergency systems can be designed as one or more of the following:

1. *One storage battery or a group of storage batteries* provided with an automatic battery-charging means. (See also Article 480.)

2. *A generator set driven by a prime mover*, acceptable to the authority having jurisdiction, and with adequate capacity to carry the maximum load connected. Prime movers may be internal-combustion engines, steam or gas turbines, or other approved types of mechanical drivers. A storage battery used to start the prime mover must be provided with an automatic battery-charging means. An on-site fuel supply that is sufficient to operate internal-combustion engines at full load for 2 hours must also be available.

Off-site fuel supplies such as natural gas or piped steam may be used where experience has demonstrated their reliability. Off-site fuel supplies may also be used where they will provide greater reliability than gasoline or diesel engines or in isolated areas where maintenance or refueling could be a problem.

Some types of drivers, particularly large ones, may take longer than 10 seconds to accelerate and develop generator voltage. Gas and steam turbines and large internal-combustion engines may have prolonged starting times. Depending on the specific loads, short-time supply could be provided by an uninterruptible power supply; a generator shared with other loads; or a generator with limited emergency supply, such as an expander, a steam turbine, or a waste heat system.

3. *Uninterruptible power supplies (UPS)*, which generally include a rectifier, a storage battery, and an inverter to ac. Uninterruptible power supplies may be very complex systems with redundant components and high-speed solid-state switching. A common practice is to include an automatic bypass for UPS malfunction to permit maintenance.

4. *The use of a separate service*, which requires a judgment by the authority having jurisdiction. Such judgment should be based on the nature of the emergency loads and the expected reliability of the other available sources.

**(F) Unit Equipment.** Individual unit equipment for emergency illumination shall consist of the following:

- (1) A rechargeable battery
- (2) A battery charging means
- (3) Provisions for one or more lamps mounted on the equipment, or shall be permitted to have terminals for remote lamps, or both
- (4) A relaying device arranged to energize the lamps automatically upon failure of the supply to the unit equipment

The batteries shall be of suitable rating and capacity to supply and maintain at not less than 87½ percent of the nominal battery voltage for the total lamp load associated with the unit for a period of at least 1½ hours, or the unit equipment shall supply and maintain not less than 60 percent of the initial emergency illumination for a period of at least 1½ hours. Storage batteries, whether of the acid or alkali type, shall be designed and constructed to meet the requirements of emergency service.

Unit equipment shall be permanently fixed in place (i.e., not portable) and shall have all wiring to each unit installed in accordance with the requirements of any of the wiring methods in Chapter 3. Flexible cord-and-plug connection shall be permitted, provided that the cord does not exceed 900 mm (3 ft) in length. The branch circuit feeding the unit equipment shall be the same branch circuit as that serving the normal lighting in the area and connected ahead of any local switches. The branch circuit that feeds unit equipment shall be clearly identified at the distribution panel. Emergency luminaires that obtain power from a unit equipment and are not part of the unit equipment shall be

wired to the unit equipment as required by 700.10 and by one of the wiring methods of Chapter 3.

Unit equipment must be permanently fixed in place, usually by mounting screws that are accessible only from within the unit. One or more lamps may be mounted on or remote from the unit. The unit should be located where it can be readily checked or tested for proper performance. See Exhibit 700.9.

Unit equipment is intended to provide illumination for the area where it is installed. For instance, if a unit is located in a corridor, it must be connected to the branch circuit supplying the normal corridor lights (on the line side of any switching arrangements). If normal power fails, the unit automatically energizes the unit lamps, restoring illumination to the corridor. A separate circuit is not permitted for unit equipment [except as noted in Exception No. 1 to 700.12(F)] because, if applied to the preceding example, failure of the normal corridor circuit would not affect the unit equipment, and the corridor would remain dark. The branch circuit feeding the unit must be identified at the panelboard.

**EXHIBIT 700.9** Self-contained, fully automatic unit equipment for operating emergency lighting located on the unit or for remotely located exit signs or lighting heads. (Courtesy of the International Association of Electrical Inspectors)

*Exception No. 1: In a separate and uninterrupted area supplied by a minimum of three normal lighting circuits, a separate branch circuit for unit equipment shall be permitted if it originates from the same panelboard as that of the normal lighting circuits and is provided with a lock-on feature.*

*Exception No. 2: Remote heads providing lighting for the exterior of an exit door shall be permitted to be supplied by the unit equipment serving the area immediately inside the exit door.*

Exception No. 2 to 700.12(F) permits unit equipment located within the building to be the source for remote heads (luminaires) installed on the exterior of the building or structure that provide illumination for the egress path on the exterior side of an exit door. Prior to the 2011 *Code*, outside unit equipment was required to be supplied from the outside lighting circuit. The exception permits unit equipment serving the area immediately inside the exit door to supply remote emergency luminaires installed outside the exit door. The normal lighting branch circuit for the area inside the exit door can be used to supply unit equipment that in turn supplies emergency luminaires installed inside and outside the exit door. Upon interruption of the normal lighting branch circuit for this area, the indoor and outdoor emergency luminaires will activate, even if the normal branch circuit for exterior lighting remains energized.

## IV. Emergency System Circuits for Lighting and Power

### 700.15 Loads on Emergency Branch Circuits

No appliances and no lamps, other than those specified as required for emergency use, shall be supplied by emergency lighting circuits.

### 700.16 Emergency Illumination

Emergency illumination shall include all required means of egress lighting, illuminated exit signs, and all other lights specified as necessary to provide required illumination.

Emergency lighting systems shall be designed and installed so that the failure of any individual lighting element, such as the burning out of a lamp, cannot leave in total darkness any space that requires emergency illumination.

Where high-intensity discharge lighting such as high- and low-pressure sodium, mercury vapor, and metal halide is used as the sole source of normal illumination, the emergency lighting system shall be required to operate until normal illumination has been restored.

*Exception: Alternative means that ensure emergency lighting illumination level is maintained shall be permitted.*

High-intensity discharge (HID) fixtures take some time to start once they are energized. Therefore, if HID fixtures are the sole source of normal illumination in an area, the *Code* requires that the emergency lighting system operate not only until the normal system is returned to service but also until the HID fixtures provide illumination. This may require a timing circuit, photoelectric monitoring system, or the equivalent.

### 700.17 Branch Circuits for Emergency Lighting

Branch circuits that supply emergency lighting shall be installed to provide service from a source complying with 700.12 when the normal supply for lighting is interrupted. Such installations shall provide either of the following:

- (1) An emergency lighting supply, independent of the normal lighting supply, with provisions for automatically transferring the emergency lights upon the event of failure of the normal lighting branch circuit
- (2) Two or more branch circuits supplied from separate and complete systems with independent power sources. One of the two power sources and systems shall be part of the emergency system, and the other shall be permitted to be part of the normal power source and system. Each system shall provide sufficient power for emergency lighting purposes.

Unless both systems are used for regular lighting purposes and are both kept lighted, means shall be provided for automatically energizing either system upon failure of the other. Either or both systems shall be permitted to be a part of the general lighting of the protected occupancy if circuits supplying lights for emergency illumination are installed in accordance with other sections of this article.

Section 700.17 provides requirements on how these branch circuits for emergency lighting are to be installed. The emergency lighting branch circuits are to be arranged in accordance with either 700.17(1) or 700.17(2). The objective of these two approaches is to not leave an area in total darkness when an interruption of power to the normal lighting branch circuit(s) occurs.

The terms *normal* and *branch circuit* in 700.17(1) indicate that the emergency lighting supply must be independent of the normal lighting supply and that it must automatically operate when there is a failure of the branch circuit(s) supplying the normal lighting. Section 700.17(2) clarifies that the requirement of this provision is for the area requiring the emergency lighting to be supplied by a minimum of two branch circuits that originate from separate systems with different power sources. Unlike 700.17(1) where a failure of the normal lighting branch circuit activates the emergency lighting supply, an area supplied by only one emergency lighting branch circuit will be in total darkness if there is a failure of that branch circuit. For example, if a single branch circuit supplied by an emergency lighting branch circuit panelboard is being used to supply the general lighting in a stairwell (means of egress), a failure of the branch circuit supplying the stairwell plunges that area into total darkness. If two branch circuits from separate systems are run to the stairwell as specified by 700.17(2), it is unlikely that both

circuits supplying luminaires in the stairway would fail simultaneously, therefore the risk to occupants created by total darkness is minimized.

### 700.18 Circuits for Emergency Power

For branch circuits that supply equipment classed as emergency, there shall be an emergency supply source to which the load will be transferred automatically upon the failure of the normal supply.

## V. Control — Emergency Lighting Circuits

### 700.20 Switch Requirements

The switch or switches installed in emergency lighting circuits shall be arranged so that only authorized persons have control of emergency lighting.

*Exception No. 1: Where two or more single-throw switches are connected in parallel to control a single circuit, at least one of these switches shall be accessible only to authorized persons.*

*Exception No. 2: Additional switches that act only to put emergency lights into operation but not disconnect them shall be permissible.*

Switches connected in series or 3- and 4-way switches shall not be used.

### 700.21 Switch Location

All manual switches for controlling emergency circuits shall be in locations convenient to authorized persons responsible for their actuation. In facilities covered by Articles 518 and 520, a switch for controlling emergency lighting systems shall be located in the lobby or at a place conveniently accessible thereto.

In no case shall a control switch for emergency lighting be placed in a motion-picture projection booth or on a stage or platform.

*Exception: Where multiple switches are provided, one such switch shall be permitted in such locations where arranged so that it can only energize the circuit but cannot de-energize the circuit.*

### 700.22 Exterior Lights

Those lights on the exterior of a building that are not required for illumination when there is sufficient daylight shall be permitted to be controlled by an automatic light-actuated device.

### 700.23 Dimmer Systems

A dimmer system containing more than one dimmer and listed for use in emergency systems shall be permitted to be used as a control device for energizing emergency lighting circuits. Upon failure of normal power, the dimmer system shall be permitted to selectively energize only those branch circuits required to provide minimum emergency illumination. All branch circuits supplied by the dimmer system cabinet shall comply with the wiring methods of Article 700.

Section 700.23 permits the use of dimmer systems that are listed for emergency system use and that contain more than one dimmer. These systems include a method to sense failure of normal power and selectively energize branch circuits fed from the dimmer cabinet, regardless of the setting of control switches or panels normally used to control the dimmer system. Dimmer systems are usually supplied by a feeder that is transferred from the normal system to the emergency system by a transfer switch. Such systems are permitted to selectively energize only those branch circuits that provide the required emergency illumination. See Exhibit 700.10.

**EXHIBIT 700.10** An example of a label for a dimmer system that is also listed for emergency system use. (Courtesy of Electronic Theatre Controls, Inc.)

### 700.24 Automatic Load Control Relay

If an emergency lighting load is automatically energized upon loss of the normal supply, a listed automatic load control relay shall be permitted to energize the load. The load control relay shall not be used as transfer equipment.

Automatic load control relays are a new class of device that has been introduced in the last few years. These devices were traditionally part of emergency unit equipment but UL

now lists stand-alone devices under ANSI/UL 924, *Standard for Emergency Lighting and Power Equipment*. Proper application of these devices requires knowledge of the function they are listed to perform in an emergency circuit.

Load control relays listed to UL 924 are not to be used to transfer a load between two nonsynchronous power sources; only transfer equipment listed to UL 1008 is suitable for this application. Load control relays are not suitable for transfer between two nonsynchronous power sources as they do not have mechanisms required by UL 1008 to prevent inadvertent connection of the normal and emergency sources, and they do not undergo fault-current evaluation that is required of UL 1008 for transfer switches.

In addition, the UL *White Book* differentiates automatic transfer switches (product category WPWR) from automatic load control relays (product category FTBR). (The four-letter code in parentheses is the UL product category guide designations.)

Section 700.24 provides requirements for implementation of automatic load control relays and specifies these devices for transferring a load from one source to another.

## VI. Overcurrent Protection

### 700.25 Accessibility

The branch-circuit overcurrent devices in emergency circuits shall be accessible to authorized persons only.

### 700.26 Ground-Fault Protection of Equipment

The alternate source for emergency systems shall not be required to have ground-fault protection of equipment with automatic disconnecting means. Ground-fault indication of the emergency source shall be provided in accordance with 700.6(D).

### 700.27 Coordination.

Emergency system(s) overcurrent devices shall be selectively coordinated with all supply side overcurrent protective devices.

*Exception: Selective coordination shall not be required between two overcurrent devices located in series if no loads are connected in parallel with the downstream device.*

Section 700.27 requires that all emergency system overcurrent devices be selectively coordinated with the overcurrent devices installed on their supply side. The term *coordination* (*selective*), as defined in Article 100, indicates that a selectively coordinated system is one where the operation of the overcurrent protective scheme localizes an overcurrent con-

dition to the circuit conductors or equipment in which an overload or fault (short circuit or ground fault) has occurred. Because the purpose of an emergency system is to provide power to essential life safety systems in a building or facility, a selectively coordinated overcurrent protection scheme that localizes and minimizes the extent of an interruption of power due to the opening of a protective device is a critical safety element.

Continuity of operation of illumination for occupant evacuation or maintaining continuity of operation of essential safety equipment such as smoke evacuation systems is necessary for occupant safety during a fire or other emergency. Simply put, an overcurrent event (overload, short circuit, or ground fault) in a 20-ampere branch circuit cannot cause the feeder protective device supplying the branch-circuit panelboard to open. This coordination must be carried through each level of distribution that supplies power to the emergency system.

Design and subsequent verification of electrical system coordination can be achieved only through a coordination study that entails detailed knowledge of electrical supply system fault-current characteristics and a design that integrates overcurrent protective devices that react to overcurrent and interact with each other in such a manner that the objective of minimizing outages by localizing the overcurrent problem and isolating that part of the emergency system can be achieved. Note that modifications to the electrical system subsequent to the initial design and installation can significantly impact the original implementation of the coordinated system. For additional discussion on selective coordination, see the commentary for 620.62 and Exhibit 620.8.

The exception to 700.27 recognizes devices that are in series where the upstream device has no other loads as well as series-rated systems where the immediately upstream device will open before the downstream device.

## I. General

### 701.1 Scope

The provisions of this article apply to the electrical safety of the installation, operation, and maintenance of legally required standby systems consisting of circuits and equipment intended to supply, distribute, and control electricity to required facilities for illumination or power, or both, when the normal electrical supply or system is interrupted.

The systems covered by this article consist only of those that are permanently installed in their entirety, including the power source.

Informational Note No. 1: For additional information, see NFPA 99-2005, *Standard for Health Care Facilities*.

Informational Note No. 2: For further information regarding performance of emergency and standby power systems, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

Informational Note No. 3: For further information, see ANSI/IEEE 446-1995, *Recommended Practice for Emergency and Standby Power Systems for Industrial and Commercial Applications*.

Legally required standby systems are intended to provide electric power to aid in fire fighting, rescue operations, control of health hazards, and similar operations. In comparison, emergency systems (see Article 700) are those systems essential for safety to life. Optional standby systems (see Article 702) are those in which failure can cause physical discomfort, serious interruption of an industrial process, damage to process equipment, or disruption of business, for example.

The requirements for legally required standby systems are much the same as for emergency systems, except for a few differences. When normal power is lost, legally required systems must be able to supply standby power in 60 seconds or less, instead of the 10 seconds or less required of emergency systems. Wiring for legally required standby systems may occupy the same raceways, cables, boxes, and cabinets as other general wiring, whereas wiring for emergency systems must be kept entirely independent of other wiring. Legally required standby systems take second priority to emergency systems if they are involved in sharing an alternate supply and/or load shedding or peak shaving schemes.

### 701.2 Definition

**Legally Required Standby Systems.** Those systems required and so classed as legally required standby by municipal, state, federal, or other codes or by any governmental agency having jurisdiction. These systems are intended to automatically supply power to selected loads (other than those classed as emergency systems) in the event of failure of the normal source.

Informational Note: Legally required standby systems are typically installed to serve loads, such as heating and refrigeration systems, communications systems, ventilation and smoke removal systems, sewage disposal, lighting systems, and industrial processes, that, when stopped during any interruption of the normal electrical supply, could create hazards or hamper rescue or fire-fighting operations.

### 701.3 Tests and Maintenance

**(A) Conduct or Witness Test.** The authority having jurisdiction shall conduct or witness a test of the complete system upon installation.

**(B) Tested Periodically.** Systems shall be tested periodically on a schedule and in a manner acceptable to the authority having jurisdiction to ensure the systems are maintained in proper operating condition.

**(C) Battery Systems Maintenance.** Where batteries are used for control, starting, or ignition of prime movers, the authority having jurisdiction shall require periodic maintenance.

**(D) Written Record.** A written record shall be kept on such tests and maintenance.

**(E) Testing Under Load.** Means for testing legally required standby systems under load shall be provided.

Informational Note: For testing and maintenance procedures of emergency power supply systems (EPSSs), see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

#### 701.4 Capacity and Rating

A legally required standby system shall have adequate capacity and rating for the supply of all equipment intended to be operated at one time. Legally required standby system equipment shall be suitable for the maximum available fault current at its terminals.

The legally required standby alternate power source shall be permitted to supply both legally required standby and optional standby system loads under either of the following conditions:

- (1) Where the alternate source has adequate capacity to handle all connected loads
- (2) Where automatic selective load pickup and load shedding is provided that will ensure adequate power to the legally required standby circuits

Selective load pickup and load shedding are not required if the generator has sufficient capacity to supply all connected loads.

#### 701.5 Transfer Equipment

**(A) General.** Transfer equipment, including automatic transfer switches, shall be automatic and identified for standby use and approved by the authority having jurisdiction. Transfer equipment shall be designed and installed to prevent the inadvertent interconnection of normal and alternate sources of supply in any operation of the transfer equipment. Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.

Section 701.5(A) allows parallel operation of the generation equipment with the normal source as long as the requirements of Article 705 are met. Traditional automatic transfer switches are not designed to permit parallel operation of generation equipment and the normal source. Therefore, traditional automatic transfer switches need not comply with Article 705. However, certain automatic transfer switch configurations are intentionally designed to briefly (for a few

cycles) parallel the generation equipment with the normal source upon load transfer from generator to normal source. This load transfer can occur with minimal disturbance or effect on the load. Transfer switches that employ this type of paralleling must comply with Article 705.

**(B) Bypass Isolation Switches.** Means to bypass and isolate the transfer switch equipment shall be permitted. Where bypass isolation switches are used, inadvertent parallel operation shall be avoided.

**(C) Automatic Transfer Switches.** Automatic transfer switches shall be electrically operated and mechanically held. Automatic transfer switches, rated 600 VAC and below, shall be listed for emergency use.

The intent of 701.5(C) is to ensure that relay contacts are mechanically held in the event of coil failure. This requirement also correlates with NFPA 110, *Standard for Emergency and Standby Power Systems*.

When standby systems are tested, both the normal and the standby system are energized. If the two sources are not synchronized, as much as twice the rated voltage may exist across the transfer switch contacts. Some listed transfer switches are designed and tested to be suitable for switching between out-of phase power sources. Other protection methods may be employed, such as a mechanical interlock that prevents inadvertent interconnection, or an electronic method that prevents both systems from being interconnected.

#### 701.6 Signals

Audible and visual signal devices shall be provided, where practicable, for the purposes described in 701.6(A), (B), (C), and (D).

**(A) Derangement.** To indicate derangement of the standby source.

**(B) Carrying Load.** To indicate that the standby source is carrying load.

**(C) Not Functioning.** To indicate that the battery charger is not functioning.

Informational Note: For signals for generator sets, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

**(D) Ground Fault.** To indicate a ground fault in solidly grounded wye, legally required standby systems of more

than 150 volts to ground and circuit-protective devices rated 1000 amperes or more. The sensor for the ground-fault signal devices shall be located at, or ahead of, the main system disconnecting means for the legally required standby source, and the maximum setting of the signal devices shall be for a ground-fault current of 1200 amperes. Instructions on the course of action to be taken in event of indicated ground fault shall be located at or near the sensor location.

**Informational Note:** For signals for generator sets, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

Section 701.6(D) clarifies that ground-fault indication is required for legally required standby systems. Although 701.26 specifies that ground-fault protection of equipment is not required to be provided on the alternate source for legally required systems, ground faults can occur on such systems, and they can result in equipment burndown. Because of the importance of legally required systems, automatic disconnect in the event of a ground fault is inappropriate. Detection of such a fault, however, is desirable so that the condition can be corrected.

## 701.7 Signs

**(A) Mandated Standby.** A sign shall be placed at the service entrance indicating type and location of on-site legally required standby power sources.

A sign is required at the service equipment that indicates the type and location of an emergency source.

*Exception: A sign shall not be required for individual unit equipment as specified in 701.12(G).*

**(B) Grounding.** Where removal of a grounding or bonding connection in normal power source equipment interrupts the grounding electrode conductor connection to the alternate power source(s) grounded conductor, a warning sign shall be installed at the normal power source equipment stating:

### WARNING

SHOCK HAZARD EXISTS IF GROUNDING  
ELECTRODE CONDUCTOR OR BONDING JUMPER  
CONNECTION IN THIS EQUIPMENT IS REMOVED  
WHILE ALTERNATE SOURCE(S) IS ENERGIZED.

See the commentary following 700.7(B). Although that section is addressing the hazard associated with removal of grounding and bonding connections in the normal supply

equipment for an emergency system, the same hazard exists in the normal supply equipment for legally required standby systems.

## II. Circuit Wiring

### 701.10 Wiring Legally Required Standby Systems

The legally required standby system wiring shall be permitted to occupy the same raceways, cables, boxes, and cabinets with other general wiring.

## III. Sources of Power

### 701.12 General Requirements

Current supply shall be such that, in the event of failure of the normal supply to, or within, the building or group of buildings concerned, legally required standby power will be available within the time required for the application but not to exceed 60 seconds. The supply system for legally required standby purposes, in addition to the normal services to the building, shall be permitted to comprise one or more of the types of systems described in 701.12(A) through (F). Unit equipment in accordance with 701.12(G) shall satisfy the applicable requirements of this article.

In selecting a legally required standby source of power, consideration shall be given to the type of service to be rendered, whether of short-time duration or long duration.

Consideration shall be given to the location or design, or both, of all equipment to minimize the hazards that might cause complete failure due to floods, fires, icing, and vandalism.

**Informational Note:** Assignment of degree of reliability of the recognized legally required standby supply system depends on the careful evaluation of the variables at each particular installation.

**(A) Storage Battery.** A storage battery shall be of suitable rating and capacity to supply and maintain at not less than 87½ percent of system voltage the total load of the circuits supplying legally required standby power for a period of at least 1½ hours.

Batteries, whether of the acid or alkali type, shall be designed and constructed to meet the service requirements of emergency service and shall be compatible with the charger for that particular installation.

For a sealed battery, the container shall not be required to be transparent. However, for the lead acid battery that requires water additions, transparent or translucent jars shall be furnished. Automotive-type batteries shall not be used.

An automatic battery charging means shall be provided.

**(B) Generator Set.**

**(1) Prime Mover-Driven.** For a generator set driven by a prime mover acceptable to the authority having jurisdiction and sized in accordance with 701.4, means shall be provided for automatically starting the prime mover upon failure of the normal service and for automatic transfer and operation of all required electrical circuits. A time-delay feature permitting a 15-minute setting shall be provided to avoid retransfer in case of short-time re-establishment of the normal source.

**(2) Internal Combustion Engines as Prime Mover.** Where internal combustion engines are used as the prime mover, an on-site fuel supply shall be provided with an on-premises fuel supply sufficient for not less than 2 hours of full-demand operation of the system. Where power is needed for the operation of the fuel transfer pumps to deliver fuel to a generator set day tank, the pumps shall be connected to the legally required standby power system.

Section 701.12(B)(2) requires that when power is needed for the operation of the fuel transfer pumps, they must be connected to the legally required standby system.

**(3) Dual Supplies.** Prime movers shall not be solely dependent on a public utility gas system for their fuel supply or on a municipal water supply for their cooling systems. Means shall be provided for automatically transferring one fuel supply to another where dual fuel supplies are used.

*Exception: Where acceptable to the authority having jurisdiction, the use of other than on-site fuels shall be permitted where there is a low probability of a simultaneous failure of both the off-site fuel delivery system and power from the outside electrical utility company.*

**(4) Battery Power.** Where a storage battery is used for control or signal power or as the means of starting the prime mover, it shall be suitable for the purpose and shall be equipped with an automatic charging means independent of the generator set.

**(5) Outdoor Generator Sets.** Where an outdoor housed generator set is equipped with a readily accessible disconnecting means located within sight of the building or structure supplied, an additional disconnecting means shall not be required where ungrounded conductors serve or pass through the building or structure. The disconnecting means shall meet the requirements of 225.36.

Section 701.12(B)(5) clarifies the requirements for the disconnecting means for an outdoor generator set. The disconnecting

means on the generator can be used as the disconnecting means required in 225.31, provided the disconnecting means is readily accessible and is within sight of the building. The disconnecting means must also be suitable for use as service equipment in accordance with 225.36. See the definitions of the terms *accessible*, *readily*, and *in sight from* in Article 100.

**(C) Uninterruptible Power Supplies.** Uninterruptible power supplies used to provide power for legally required standby systems shall comply with the applicable provisions of 701.12(A) and (B).

**(D) Separate Service.** Where approved, a separate service shall be permitted as a legally required source of standby power. This service shall be in accordance with the applicable provisions of Article 230, with separate service drop or lateral sufficiently remote electrically and physically from any other service to minimize the possibility of simultaneous interruption of supply from an occurrence in another service.

**(E) Connection Ahead of Service Disconnecting Means.** Where acceptable to the authority having jurisdiction, connections located ahead of and not within the same cabinet, enclosure, or vertical switchboard section as the service disconnecting means shall be permitted. The legally required standby service shall be sufficiently separated from the normal main service disconnecting means to minimize simultaneous interruption of supply through an occurrence within the building or groups of buildings served.

Informational Note: See 230.82 for equipment permitted on the supply side of a service disconnecting means.

Where a legally required standby system is supplied by conductors tapped to the normal service conductors (connection required to be on line side of the normal service disconnecting means), 230.82 requires that the tapped conductors be installed in accordance with all of the requirements for service-entrance conductors and that the conductors terminate in equipment suitable for use as service equipment. These requirements help ensure that the legally required standby system disconnecting means can safely interrupt the fault current available from the utility and that the tapped conductors, which do not have short-circuit and ground-fault protection, are not run through the interior of a building.

**(F) Fuel Cell System.** Fuel cell systems used as a source of power for legally required standby systems shall be of

suitable rating and capacity to supply and maintain the total load for not less than 2 hours of full-demand operation.

Installation of a fuel cell system shall meet the requirements of Parts II through VIII of Article 692.

Where a single fuel cell system serves as the normal supply for the building or group of buildings concerned, it shall not serve as the sole source of power for the legally required standby system.

**(G) Unit Equipment.** Individual unit equipment for legally required standby illumination shall consist of the following:

- (1) A rechargeable battery
- (2) A battery charging means
- (3) Provisions for one or more lamps mounted on the equipment and shall be permitted to have terminals for remote lamps
- (4) A relaying device arranged to energize the lamps automatically upon failure of the supply to the unit equipment

The batteries shall be of suitable rating and capacity to supply and maintain at not less than 87½ percent of the nominal battery voltage for the total lamp load associated with the unit for a period of at least 1½ hours, or the unit equipment shall supply and maintain not less than 60 percent of the initial legally required standby illumination for a period of at least 1½ hours. Storage batteries, whether of the acid or alkali type, shall be designed and constructed to meet the requirements of emergency service.

Unit equipment shall be permanently fixed in place (i.e., not portable) and shall have all wiring to each unit installed in accordance with the requirements of any of the wiring methods in Chapter 3. Flexible cord-and-plug connection shall be permitted, provided that the cord does not exceed 900 mm (3 ft) in length. The branch circuit feeding the unit equipment shall be the same branch circuit as that serving the normal lighting in the area and connected ahead of any local switches. Legally required standby luminaires that obtain power from a unit equipment and are not part of the unit equipment shall be wired to the unit equipment by one of the wiring methods of Chapter 3.

*Exception: In a separate and uninterrupted area supplied by a minimum of three normal lighting circuits, a separate branch circuit for unit equipment shall be permitted if it originates from the same panelboard as that of the normal lighting circuits and is provided with a lock-on feature.*

## IV. Overcurrent Protection

### 701.25 Accessibility

The branch-circuit overcurrent devices in legally required standby circuits shall be accessible to authorized persons only.

### 701.26 Ground-Fault Protection of Equipment

The alternate source for legally required standby systems shall not be required to have ground-fault protection of equipment with automatic disconnecting means. Ground-fault indication of the legally required standby source shall be provided in accordance with 701.6(D).

### 701.27 Coordination

Legally required standby system(s) overcurrent devices shall be selectively coordinated with all supply-side overcurrent protective devices.

*Exception: Selective coordination shall not be required between two overcurrent devices located in series if no loads are connected in parallel with the downstream device.*

See the commentary regarding selective coordination for emergency systems following 700.27.

    - (A) Separately Derived System
    - (B) Nonseparately Derived System
  - 702.12 Outdoor Generator Sets

## I. General

### 702.1 Scope

The provisions of this article apply to the installation and operation of optional standby systems.

The systems covered by this article consist of those that are permanently installed in their entirety, including prime movers, and those that are arranged for a connection to a

premises wiring system from a portable alternate power supply.

Article 702 applies not only to permanently installed generators and prime movers but also to portable alternate power supplies that can be connected to an optional standby system. For example, upon failure of an optional standby generator at a frozen food processing plant, a vehicle-mounted generator can be brought in and connected to the plant's optional standby system, which has provisions for such a connection. Events such as carnivals and fairs require the use of portable generators. See Exhibit 702.1.

**EXHIBIT 702.1** A trailer (vehicle) mounted portable generator. (Courtesy of the International Association of Electrical Inspectors)

Optional standby systems are those that upon failing can cause physical discomfort, serious interruption of an industrial process, damage to process equipment, or disruption of business, whereas emergency systems (see Article 700) are those systems essential for safety to life and legally required standby systems (see Article 701) are intended to provide electric power to aid fire fighting, rescue operations, control of health hazards, and similar operations.

The installation of optional standby systems at one-family dwelling units has seen a significant increase in recent years. Spikes in the increased use of these systems can be directly related to natural disasters, resulting in prolonged outages of utility power.

## 702.2 Definition

**Optional Standby Systems.** Those systems intended to supply power to public or private facilities or property where life safety does not depend on the performance of the system. Optional standby systems are intended to supply

on-site generated power to selected loads either automatically or manually.

**Informational Note:** Optional standby systems are typically installed to provide an alternate source of electric power for such facilities as industrial and commercial buildings, farms, and residences and to serve loads such as heating and refrigeration systems, data processing and communications systems, and industrial processes that, when stopped during any power outage, could cause discomfort, serious interruption of the process, damage to the product or process, or the like.

## 702.4 Capacity and Rating

**(A) Available Short-Circuit Current.** Optional standby system equipment shall be suitable for the maximum available short-circuit current at its terminals.

**(B) System Capacity.** The calculations of load on the standby source shall be made in accordance with Article 220 or by another approved method.

**(1) Manual Transfer Equipment.** Where manual transfer equipment is used, an optional standby system shall have adequate capacity and rating for the supply of all equipment intended to be operated at one time. The user of the optional standby system shall be permitted to select the load connected to the system.

**(2) Automatic Transfer Equipment.** Where automatic transfer equipment is used, an optional standby system shall comply with (2)(a) or (2)(b).

(a) **Full Load.** The standby source shall be capable of supplying the full load that is transferred by the automatic transfer equipment.

(b) **Load Management.** Where a system is employed that will automatically manage the connected load, the standby source shall have a capacity sufficient to supply the maximum load that will be connected by the load management system.

The standby source must have the capacity to supply all of the loads connected to it, unless an automatic load management system is used to ensure that the transferred load does not overload the source. This requirement applies only to systems where the switching between power sources occurs automatically.

## 702.5 Transfer Equipment

Transfer equipment shall be suitable for the intended use and designed and installed so as to prevent the inadvertent interconnection of normal and alternate sources of supply in

any operation of the transfer equipment. Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.

Transfer equipment, located on the load side of branch circuit protection, shall be permitted to contain supplemental overcurrent protection having an interrupting rating sufficient for the available fault current that the generator can deliver. The supplementary overcurrent protection devices shall be part of a listed transfer equipment.

Transfer equipment shall be required for all standby systems subject to the provisions of this article and for which an electric utility supply is either the normal or standby source.

Section 702.5 allows parallel operation of the generation equipment with the normal source as long as the requirements of Article 705 are met. Traditional automatic transfer switches are not designed to permit parallel operation of generation equipment and the normal source. Therefore, traditional automatic transfer switches need not comply with Article 705. However, certain automatic transfer switch configurations are intentionally designed to briefly (for a few cycles) parallel the generation equipment with the normal source upon load transfer from generator to normal source. This load transfer can occur with minimal disturbance or effect on the load. Transfer switches that employ this type of paralleling must comply with Article 705.

*Exception: Temporary connection of a portable generator without transfer equipment shall be permitted where conditions of maintenance and supervision ensure that only qualified persons service the installation and where the normal supply is physically isolated by a lockable disconnecting means or by disconnection of the normal supply conductors.*

The exception to 702.5 provides requirements for the connection of loads to a generator without the use of a transfer switch, where the installation is under the supervision of qualified service personnel. Such applications often occur when necessary for equipment maintenance or breakdown or when an extended power outage occurs. In such instances, a portable generator can be brought to a facility and connected to the existing distribution system. Supervision by qualified personnel is critical to ensuring that a dangerous backfeed condition is not created by connecting the generator to the system without the benefit of transfer equipment.

## 702.6 Signals

Audible and visual signal devices shall be provided, where practicable, for the following purposes.

(1) **Derangement.** To indicate derangement of the optional standby source.

(2) **Carrying Load.** To indicate that the optional standby source is carrying load.

*Exception: Signals shall not be required for portable standby power sources.*

## 702.7 Signs

(A) **Standby.** A sign shall be placed at the service-entrance equipment that indicates the type and location of on-site optional standby power sources. A sign shall not be required for individual unit equipment for standby illumination.

A sign is required at the service equipment that indicates the type and location of an emergency source.

(B) **Grounding.** Where removal of a grounding or bonding connection in normal power source equipment interrupts the grounding electrode conductor connection to the alternate power source(s) grounded conductor, a warning sign shall be installed at the normal power source equipment stating:

**WARNING**  
**SHOCK HAZARD EXISTS IF GROUNDING**  
**ELECTRODE CONDUCTOR OR BONDING JUMPER**  
**CONNECTION IN THIS EQUIPMENT IS REMOVED**  
**WHILE ALTERNATE SOURCE(S) IS ENERGIZED.**

See the commentary following 700.7(B). Although that section is addressing the hazard associated with removal of grounding and bonding connections in the normal supply equipment for an emergency system, the same hazard exists in the normal supply equipment for optional standby systems.

## II. Wiring

### 702.10 Wiring Optional Standby Systems

The optional standby system wiring shall be permitted to occupy the same raceways, cables, boxes, and cabinets with other general wiring.

•

### 702.11 Portable Generator Grounding

(A) **Separately Derived System.** Where a portable optional standby source is used as a separately derived system, it shall be grounded to a grounding electrode in accordance with 250.30.

**(B) Nonseparately Derived System.** Where a portable optional standby source is used as a nonseparately derived system, the equipment grounding conductor shall be bonded to the system grounding electrode.

### 702.12 Outdoor Generator Sets

Where an outdoor housed generator set is equipped with a readily accessible disconnecting means located within sight of the building or structure supplied, an additional disconnecting means shall not be required where ungrounded conductors serve or pass through the building or structure. The disconnecting means shall meet the requirements of 225.36.

The disconnecting means must be suitable for use as service equipment in accordance with 225.36.

### I. General

#### 705.1 Scope

This article covers installation of one or more electric power production sources operating in parallel with a primary source(s) of electricity.

Informational Note: Examples of the types of primary sources include a utility supply or an on-site electric power source(s).

Article 705 sets forth basic safety requirements for the installation of generators and other types of power production sources that are interconnected and operate in parallel as distributed generation. Power sources include any systems that produce electric power, including not only electric utility sources but also on-premises sources ranging from rotating generators (see Article 445) to solar photovoltaic systems (see Article 690) to fuel cells (see Article 692).

Article 705 addresses the basic safety requirements specifically related to parallel operation for the generators and other power sources, the power system that interconnects the power sources, and the equipment connected to these systems. The proper application of these systems requires a thorough review of the entire power system.

705.2 Definitions

**Hybrid System.** A system comprised of multiple power sources. These power sources could include photovoltaic, wind, micro-hydro generators, engine-driven generators, and others, but do not include electric power production and distribution network systems. Energy storage systems such as batteries, flywheels, or superconducting magnetic storage equipment do not constitute a power source for the purpose of this definition.

**Point of Common Coupling.** The point at which the power production and distribution network and the customer interface occurs in an interactive system. Typically, this is the load side of the power network meter.

**Power Production Equipment.** The generating source, and all distribution equipment associated with it, that generates electricity from a source other than a utility supplied service.

Informational Note: Examples of power production equipment include such items as generators, solar photovoltaic systems, and fuel cell systems.

The definition of *power production equipment* in 705.2 provides clarity and clearly identifies these sources to be other than a utility-supplied service. See 705.21 for requirements on disconnecting means for power production equipment.

**Utility-Interactive Inverter Output Circuit.** The conductors between the utility interactive inverter and the service equipment or another electric power production source, such as a utility, for electrical production and distribution network.

705.3 Other Articles

Interconnected electric power production sources shall comply with this article and also with the applicable requirements of the articles in Table 705.3.

TABLE 705.3 Other Articles

Equipment/System	Article
Generators	445
Solar photovoltaic systems	690
Fuel cell systems	692
Emergency systems	700
Legally required standby systems	701
Optional standby systems	702

705.4 Equipment Approval

All equipment shall be approved for the intended use. Utility-interactive inverters for interconnection systems shall be listed and identified for interconnection service.

705.6 System Installation

Installation of one or more electrical power production sources operating in parallel with a primary source(s) of electricity shall be installed only by qualified persons.

This requirement emphasizes that interconnected power production sources introduce hazards unique to systems operating in parallel. Part of being a *qualified person* is having the skills and knowledge to recognize the hazards associated with these systems. Special training for persons working on interconnected systems is key to ensuring that personnel can work safely on these systems. The increased use of on-site renewable energy sources that are interconnected with utility-supplied power and/or other on-site sources makes it necessary for personnel to be *qualified* from the standpoint of personal safety.

Informational Note: See Article 100 for the definition of *Qualified Person*.

705.10 Directory

A permanent plaque or directory, denoting all electric power sources on or in the premises, shall be installed at each service equipment location and at locations of all electric power production sources capable of being interconnected.

*Exception: Installations with large numbers of power production sources shall be permitted to be designated by groups.*

705.12 Point of Connection

The output of an interconnected electric power source shall be connected as specified in 705.12(A), (B), (C), or (D).

**(A) Supply Side.** An electric power production source shall be permitted to be connected to the supply side of the service disconnecting means as permitted in 230.82(6). The sum of the ratings of all overcurrent devices connected to power production sources shall not exceed the rating of the service.

**(B) Integrated Electrical Systems.** The outputs shall be permitted to be interconnected at a point or points elsewhere on the premises where the system qualifies as an integrated electrical system and incorporates protective equipment in accordance with all applicable sections of Article 685.

**(C) Greater Than 100 kW.** The outputs shall be permitted to be interconnected at a point or points elsewhere on the premises where all of the following conditions are met:

- (1) The aggregate of non-utility sources of electricity has a capacity in excess of 100 kW, or the service is above 1000 volts.

- (2) The conditions of maintenance and supervision ensure that qualified persons service and operate the system.
- (3) Safeguards, documented procedures, and protective equipment are established and maintained.

In general, the point of interconnection must be at the premises service disconnecting means. This requirement is intended to prevent the indiscriminate interconnection of small generators or other sources of power without proper protection against fire and electric shock. (See Exhibit 705.1.)

**EXHIBIT 705.1** The points of interconnection permitted by 705.12(A), (B), and (C).

Section 705.12(A) permits the electric power production source to be connected on the supply side of the utility-supplied service disconnecting means, or the source can be connected on the load side. This practice accommodates the safe work practices of many utilities, which provide a readily accessible disconnect for distributed generation.

Sections 705.12(B) and (C) recognize that generators and other power sources can be safely connected elsewhere on the premises system. These locations include where the premises has an integrated electrical system as set forth in Article 685, where the total generator capacity on premises is greater than 100 kW, and where the service is greater than 1000 volts.

**(D) Utility-Interactive Inverters.** The output of a utility-interactive inverter shall be permitted to be connected to the load side of the service disconnecting means of the other source(s) at any distribution equipment on the premises. Where distribution equipment including switchboards and panelboards is fed simultaneously by a primary source(s) of electricity and one or more utility-interactive inverters, and

where this distribution equipment is capable of supplying multiple branch circuits or feeders or both, the interconnecting provisions for the utility-interactive inverter(s) shall comply with (D)(1) through (D)(7).

**(1) Dedicated Overcurrent and Disconnect.** Each source interconnection shall be made at a dedicated circuit breaker or fusible disconnecting means.

**(2) Bus or Conductor Rating.** The sum of the ampere ratings of overcurrent devices in circuits supplying power to a busbar or conductor shall not exceed 120 percent of the rating of the busbar or conductor.

*Exception: Where the photovoltaic system has an energy storage device to allow stand-alone operation of loads, the value used in the calculation of bus or conductor loading shall be 125 percent of the rated utility-interactive current from the inverter instead of the rating of the overcurrent device between the inverter and the bus or conductor.*

The exception to 705.12(D)(2) permits an alternative to determining the load supplied by the bus or conductor. For example, because the inverter is capable of supplying only 30 amps of utility-interactive current to the panel and to the utility grid, it is safe to allow 125 percent of the continuous inverter backfeed current, which is 37.5 amps ( $1.25 \times 30$ ), to be used in the 705.12(D)(2) calculation rather than the rating of the required load breaker determined by the main requirement.

**(3) Ground-Fault Protection.** The interconnection point shall be on the line side of all ground-fault protection equipment.

*Exception: Connection shall be permitted to be made to the load side of ground-fault protection, provided that there is ground-fault protection for equipment from all ground-fault current sources. Ground-fault protection devices used with supplies connected to the load-side terminals shall be identified and listed as suitable for backfeeding.*

**(4) Marking.** Equipment containing overcurrent devices in circuits supplying power to a busbar or conductor supplied from multiple sources shall be marked to indicate the presence of all sources.

**(5) Suitable for Backfeed.** Circuit breakers, if backfed, shall be suitable for such operation.

*Informational Note:* Circuit breakers that are marked “Line” and “Load” have been evaluated only in the direction marked. Circuit breakers without “Line” and “Load” have been evaluated in both directions.

**(6) Fastening.** Listed plug-in-type circuit breakers backed from utility-interactive inverters that are listed and identified as interactive shall be permitted to omit the additional fastener normally required by 408.36(D) for such applications.

**(7) Inverter Output Connection.** Unless the panelboard is rated not less than the sum of the ampere ratings of all overcurrent devices supplying it, a connection in a panelboard shall be positioned at the opposite (load) end from the input feeder location or main circuit location. The bus or conductor rating shall be sized for the loads connected in accordance with Article 220. In systems with panelboards connected in series, the rating of the first overcurrent device directly connected to the output of a utility-interactive inverter(s) shall be used in the calculations for all busbars and conductors. A permanent warning label shall be applied to the distribution equipment with the following or equivalent wording:

WARNING  
INVERTER OUTPUT CONNECTION  
DO NOT RELOCATE THIS OVERCURRENT DEVICE

### 705.14 Output Characteristics

The output of a generator or other electric power production source operating in parallel with an electrical supply system shall be compatible with the voltage, wave shape, and frequency of the system to which it is connected.

Informational Note: The term *compatible* does not necessarily mean matching the primary source wave shape.

The level and quality of output power of interconnected sources must be controlled to facilitate proper operation of the interconnected generator or other power production source and the electric system. Control of the generator or power production source should include real power, reactive power, and harmonic content of the output. Section 705.14 states that the interconnected equipment must be compatible with the electric supply system in voltage, wave shape, and frequency. The output characteristics of a rotating generator are significantly different from those of a solid-state power source. Their compatibility with other sources and with different types of loads is limited in different ways. Control of the driver speed causes real power (kW) to flow from an induction generator, whereas control of the prime mover torque causes real power (kW) to flow from a synchronous generator. Control of voltage causes reactive power (kVAR) to flow to or from a synchronous generator, while induction generators have no means to control reactive power (kVAR) flow and continuously draw reactive power.

The parallel operation of generators is a complex balance of several variables that are design parameters and therefore beyond the scope of the *Code*.

Where either the power source or the loads have solid-state equipment, such as inverters, uninterruptible power supplies (UPS), or solid-state variable-speed drives, harmonic currents may flow in the system. (See Exhibit 705.2.) These multiples of the basic supply frequency (usually 60 Hz) cause additional heating, which may require derating of generators, transformers, cables, and motors. Special generator voltage control systems are required to avoid erratic operation or destruction of control devices. Circuit breakers may require derating if the higher harmonics become significant.

In Exhibit 705.2 (middle), motors and transformers will be driven by harmonic-rich voltage and may require derating. In Exhibit 705.2 (bottom), the source generator may require derating, and special voltage control may be needed.

**EXHIBIT 705.2** Typical output wave shapes: (top) with rotating generator and system wave shape normally encountered with motor, lighting, and heating loads; (middle) with inverter source; and (bottom) with variable speed drive, rectifier, and uninterruptible power to supply loads.

Significant magnitudes of harmonics may be inadvertently matched to system resonance and result in the opening of capacitor fuses, overheating of circuits, and erratic operation of controls. The usual solution is to detune the system by rearrangement, installation of reactors, or both.

### 705.16 Interrupting and Short-Circuit Current Rating

Consideration shall be given to the contribution of fault currents from all interconnected power sources for the interrupting and short-circuit current ratings of equipment on interactive systems.

### 705.20 Disconnecting Means, Sources

Means shall be provided to disconnect all ungrounded conductors of an electric power production source(s) from all other conductors.

### 705.21 Disconnecting Means, Equipment

Means shall be provided to disconnect power production equipment, such as utility interactive inverters or transformers associated with a power production source, from all ungrounded conductors of all sources of supply. Equipment intended to be operated and maintained as an integral part of a power production source exceeding 1000 volts shall not be required to have a disconnecting means.

#### Application Example

An example of equipment that is covered under the second sentence of 705.21 is a generator designed for 4160 volts and connected to a 13,800-volt system through a transformer. In this example, the transformer and generator are to be operated as a unit; therefore, a disconnecting means is not required between the generator and the transformer. A disconnecting means, however, is required between the transformer and the point of connection to the power system. Section 445.18 addresses the general requirements for disconnecting means associated with generators.

### 705.22 Disconnect Device

The disconnecting means for ungrounded conductors shall consist of a manually or power operable switch(es) or circuit breaker(s) with the following features:

- (1) Located where readily accessible
- (2) Externally operable without exposing the operator to contact with live parts and, if power operable, of a type that could be opened by hand in the event of a power-supply failure
- (3) Plainly indicating whether in the open (off) or closed (on) position
- (4) Having ratings not less than the load to be carried and the fault current to be interrupted. For disconnect equipment energized from both sides, a marking shall be provided to indicate that all contacts of the disconnect equipment might be energized.

*Informational Note to (4): In parallel generation systems, some equipment, including knife blade switches and fuses, is likely to be energized from both directions. See 240.40.*

- 
- (5) Simultaneous disconnect of all ungrounded conductors of the circuit
- (6) Capable of being locked in the open (off) position

A disconnecting means must serve each generating source. This disconnecting means will be the service-entrance disconnect. Still another disconnecting means may be applied to separate the grounding systems.

The basic requirement in 705.22 recognizes the success of applying switches as well as circuit breakers as the disconnecting means for ungrounded conductors. Most safe work practices on the premises use these disconnect devices.

The disconnect at the service entrance is required for disconnecting the premises wiring system from the utility. The utility safe work practices may also use this disconnect device.

### 705.30 Overcurrent Protection

Conductors shall be protected in accordance with Article 240. Equipment and conductors connected to more than one electrical source shall have a sufficient number of overcurrent devices located so as to provide protection from all sources.

**(A) Solar Photovoltaic Systems.** Solar photovoltaic systems shall be protected in accordance with Article 690.

**(B) Transformers.** Overcurrent protection for a transformer with a source(s) on each side shall be provided in accordance with 450.3 by considering first one side of the transformer, then the other side of the transformer, as the primary.

**(C) Fuel Cell Systems.** Fuel cell systems shall be protected in accordance with Article 692.

**(D) Utility-Interactive Inverters.** Utility-interactive inverters shall be protected in accordance with 705.65.

**(E) Generators.** Generators shall be protected in accordance with 705.130.

### 705.32 Ground-Fault Protection

Where ground-fault protection is used, the output of an interactive system shall be connected to the supply side of the ground-fault protection.

*Exception: Connection shall be permitted to be made to the load side of ground-fault protection, provided that there is ground-fault protection for equipment from all ground-fault current sources.*

The requirements in Article 705 are only for protection against conditions that may occur because generating sources are being operated in parallel. The installation must also meet the requirements of the referenced articles to provide the basic protection and safeguards for all equipment, whether or not the equipment is involved with more than one source.

Larger optional standby systems (see Article 702) have become more sophisticated and may involve many special relays. The more common switchgear-type relays include under- and overvoltage, under- and overfrequency, voltage-restrained overcurrent, anti-motoring, loss of excitation, overtemperature, and shutdown for derangement of the mechanical driver.

Small generator installations cannot justify the cost of switchgear-type relays. Therefore, small generator protection comprises more common devices with fewer features. Application guides for relay protection are available in manufacturers' technical literature.

#### 705.40 Loss of Primary Source

Upon loss of primary source, an electric power production source shall be automatically disconnected from all ungrounded conductors of the primary source and shall not be reconnected until the primary source is restored.

*Exception: A listed utility-interactive inverter shall be permitted to automatically cease exporting power upon loss of primary source and shall not be required to automatically disconnect all ungrounded conductors from the primary source. A listed utility-interactive inverter shall be permitted to automatically or manually resume exporting power to the utility once the primary source is restored.*

Informational Note No. 1: Risks to personnel and equipment associated with the primary source could occur if an utility interactive electric power production source can operate as an intentional island. Special detection methods are required to determine that a primary source supply system outage has occurred and whether there should be automatic disconnection. When the primary source supply system is restored, special detection methods can be required to limit exposure of power production sources to out-of-phase reconnection.

Informational Note No. 2: Induction-generating equipment on systems with significant capacitance can become self-excited upon loss of the primary source and experience severe overvoltage as a result.

A utility-interactive inverter shall be permitted to operate as a stand-alone system to supply loads that have been

disconnected from electrical production and distribution network sources.

When two interconnected power systems separate, they drift out of synchronism. When the utility and the interconnected power system separate, there is a risk of damage to the system if restoration of the utility occurs out of phase. If the timing of the reconnection is random, violent electromechanical stresses can destroy mechanical components such as gears, couplings, and shafts and can displace coils. Therefore, the premises wiring system or generator must be disconnected from the primary source.

Many technical guides are available from which to select appropriate protective systems and equipment for large systems. A limited choice of low-cost devices is still available for application to small systems. Induction generators are commonly used today. Induction generators have characteristics quite different from those of synchronous machines. They are more rugged because of the construction of the rotor, and they are less expensive because of their basic design, availability, and type of starting and control equipment. Theoretically, an induction machine can continue to run on an isolated system if a large capacitor bank provides excitation. In reality, an induction machine will probably lose stability and be shut down quickly by one of the protective devices.

#### 705.42 Loss of 3-Phase Primary Source

A 3-phase electric power production source shall be automatically disconnected from all ungrounded conductors of the interconnected systems when one of the phases of that source opens. This requirement shall not be applicable to an electric power production source providing power for an emergency or legally required standby system.

*Exception: A listed utility-interactive inverter shall be permitted to automatically cease exporting power when one of the phases of the source opens and shall not be required to automatically disconnect all ungrounded conductors from the primary source. A listed utility-interactive inverter shall be permitted to automatically or manually resume exporting power to the utility once all phases of the source are restored.*

#### 705.50 Grounding

Interconnected electric power production sources shall be grounded in accordance with Article 250.

*Exception: For direct-current systems connected through an inverter directly to a grounded service, other methods that accomplish equivalent system protection and that utilize equipment listed and identified for the use shall be permitted.*

## II. Utility-Interactive Inverters

### 705.60 Circuit Sizing and Current

**(A) Calculation of Maximum Circuit Current.** The maximum current for the specific circuit shall be calculated in accordance with 705.60 (A)(1) and (A)(2).

**(1) Inverter Source Circuit Currents.** The maximum current shall be the maximum rated input current of the inverter.

**(2) Inverter Output Circuit Current.** The maximum current shall be the inverter continuous output current rating.

**(B) Ampacity and Overcurrent Device Ratings.** Inverter system currents shall be considered to be continuous. The circuit conductors and overcurrent devices shall be sized to carry not less than 125 percent of the maximum currents as calculated in 705.60(A). The rating or setting of overcurrent devices shall be permitted in accordance with 240.4(B) and (C).

*Exception: Circuits containing an assembly together with its overcurrent device(s) that is listed for continuous operation at 100 percent of its rating shall be permitted to be utilized at 100 percent of its rating.*

### 705.65 Overcurrent Protection

**(A) Circuits and Equipment.** Inverter input circuits, inverter output circuits, and storage battery circuit conductors and equipment shall be protected in accordance with the requirements of Article 240. Circuits connected to more than one electrical source shall have overcurrent devices located so as to provide overcurrent protection from all sources.

*Exception: An overcurrent device shall not be required for circuit conductors sized in accordance with 705.60(B) and located where one of the following applies:*

- (1) There are no external sources such as parallel-connected source circuits, batteries, or backfeed from inverters.*
- (2) The short-circuit currents from all sources do not exceed the ampacity of the conductors.*

**Informational Note:** Possible backfeed of current from any source of supply, including a supply through an inverter into the inverter output circuit and inverter source circuits, is a consideration in determining whether adequate overcurrent protection from all sources is provided for conductors and modules.

**(B) Power Transformers.** Overcurrent protection for a transformer with a source(s) on each side shall be provided in accordance with 450.3 by considering first one side of the transformer, then the other side of the transformer, as the primary.

*Exception: A power transformer with a current rating on the side connected toward the utility-interactive inverter output that is not less than the rated continuous output current of the inverter shall be permitted without overcurrent protection from that source.*

Under short-circuit conditions, the anti-islanding circuits required in all utility-interactive inverters by UL 1741, *Standard for Inverters, Converters, Controllers and Interconnection System Equipment for Use With Distributed Energy Resources*, sense the near zero voltage and cause the inverters to immediately shut down.

### 705.70 Utility-Interactive Inverters Mounted in Not-Readily-Accessible Locations

Utility-interactive inverters shall be permitted to be mounted on roofs or other exterior areas that are not readily accessible. These installations shall comply with (1) through (4):

- (1) A direct-current disconnecting means shall be mounted within sight of or in the inverter.
- (2) An alternating-current disconnecting means shall be mounted within sight of or in the inverter.
- (3) An additional alternating-current disconnecting means for the inverter shall comply with 705.22.
- (4) A plaque shall be installed in accordance with 705.10.

### 705.80 Utility-Interactive Power Systems Employing Energy Storage

Utility-interactive power systems employing energy storage shall also be marked with the maximum operating voltage, including any equalization voltage, and the polarity of the grounded circuit conductor.

### 705.82 Hybrid Systems

Hybrid systems shall be permitted to be interconnected with utility-interactive inverters.

### 705.95 Ampacity of Neutral Conductor

The ampacity of the neutral conductors shall comply with either (A) or (B).

**(A) Neutral Conductor for Single Phase, 2-Wire Inverter Output.** If a single-phase, 2-wire inverter output is connected to the neutral and one ungrounded conductor (only) of a 3-wire system or of a 3-phase, 4-wire, wye-connected system, the maximum load connected between the neutral and any one ungrounded conductor plus the inverter output rating shall not exceed the ampacity of the neutral conductor.

**(B) Neutral Conductor for Instrumentation, Voltage Detection or Phase Detection.** A conductor used solely for instrumentation, voltage detection, or phase detection and connected to a single-phase or 3-phase utility-interactive inverter, shall be permitted to be sized at less than the ampacity of the other current-carrying conductors and shall be sized equal to or larger than the equipment grounding conductor.

Section 705.95 provides requirements for the ampacity of the neutral conductor for power loads in single-phase, 2-wire inverter output in 705.95(A), and for instrumentation, voltage detection, or phase detection loads in 705.95(B). If a neutral conductor is associated with a circuit supplying both power and instrumentation loads, the provisions in 705.95(A) apply to sizing of the neutral conductor.

If the inverters are not operating, the neutral must be able to carry any connected load currents. The operation of the inverters in the presence of load currents will tend to decrease currents in the neutral. If there are no loads, then the circuit must carry the full-rated output of the inverter(s). Where multiple inverters are installed and connected phase-to-neutral, consideration must be given to situations where one or more inverters could fail, be turned off, or the connected array shaded, thus eliminating any balance between the phases and increasing the neutral currents.

### 705.100 Unbalanced Interconnections

**(A) Single Phase.** Single-phase inverters for hybrid systems and ac modules in interactive hybrid systems shall not be connected to 3-phase power systems unless the interconnected system is designed so that significant unbalanced voltages cannot result.

**(B) Three Phase.** Three-phase inverters and 3-phase ac modules in interactive systems shall have all phases automatically de-energized upon loss of, or unbalanced, voltage in one or more phases unless the interconnected system is designed so that significant unbalanced voltages will not result.

## III. Generators

### 705.130 Overcurrent Protection

Conductors shall be protected in accordance with Article 240. Equipment and conductors connected to more than one electrical source shall have overcurrent devices located so as to provide protection from all sources. Generators shall be protected in accordance with 445.12.

### 705.143 Synchronous Generators

Synchronous generators in a parallel system shall be provided with the necessary equipment to establish and maintain a synchronous condition.

## I. General

### 708.1 Scope

The provisions of this article apply to the installation, operation, monitoring, control, and maintenance of the portions of the premises wiring system intended to supply, distribute, and control electricity to designated critical operations areas (DCOA) in the event of disruption to elements of the normal system.

Critical operations power systems are those systems so classed by municipal, state, federal, or other codes by any governmental agency having jurisdiction or by facility engineering documentation establishing the necessity for such a system. These systems include but are not limited to power systems, HVAC, fire alarm, security, communications, and signaling for designated critical operations areas.

Informational Note No. 1: Critical operations power systems are generally installed in vital infrastructure facilities that, if destroyed or incapacitated, would disrupt national security, the economy, public health or safety; and where enhanced electrical infrastructure for continuity of operation has been deemed necessary by governmental authority.

Informational Note No. 2: For further information on disaster and emergency management see *NFPA 1600-2010, Standard on Disaster/Emergency Management and Business Continuity Programs*.

Informational Note No. 3: For further information regarding performance of emergency and standby power systems, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

Informational Note No. 4: For further information regarding performance and maintenance of emergency systems in health care facilities, see NFPA 99-2005, *Standard for Health Care Facilities*.

Informational Note No. 5: For specification of locations where emergency lighting is considered essential to life safety, see NFPA 101-2009, *Life Safety Code*.

Informational Note No. 6: For further information on regarding physical security, see NFPA 730-2008, *Guide for Premises Security*.

Informational Note No. 7: Threats to facilities that may require transfer of operation to the critical systems include both naturally occurring hazards and human-caused events. See also A.5.3.2 of *NFPA 1600-2010*.

Informational Note No. 8: See Informative Annex F, *Availability and Reliability for Critical Operations Power Systems*; and Development and Implementation of Functional Performance Tests (FPTs) for Critical Operations Power Systems.

Informational Note No. 9: See Informative Annex G, *Supervisory Control and Data Acquisition (SCADA)*.

Article 708 addresses homeland security issues for facilities that are “mission critical.” These requirements go beyond those of Article 700, in that these electrical systems must continue to operate during the full duration of an emergency and beyond. See Exhibit 708.1. Examples of facilities that would use a critical operations power system (COPS) include police stations, fire stations, and hospitals. It may not include every one of these facilities. It would only include those facilities that are designated as critical because power must operate continuously with a robust power supply. The critical operations power systems and any other standby systems in these facilities that employ an internal combustion engine require proper exhaust ventilation, which is necessary to remove carbon monoxide.

### 708.2 Definitions

**Commissioning.** The acceptance testing, integrated system testing, operational tune-up, and start-up testing is the process by which baseline test results verify the proper operation and sequence of operation of electrical equipment, in addition to developing baseline criteria by which future trend analysis can identify equipment deterioration.

**Critical Operations Power Systems (COPS).** Power systems for facilities or parts of facilities that require continuous operation for the reasons of public safety, emergency management, national security, or business continuity.

**Designated Critical Operations Areas (DCOA).** Areas within a facility or site designated as requiring critical operations power.

**EXHIBIT 708.1** *New Hampshire Department of Safety Emergency Management Center, a typical COPS Facility: (top) facility and (bottom) facility signage.*

**Supervisory Control and Data Acquisition (SCADA).** An electronic system that provides monitoring and controls for the operation of the critical operations power system. This can include the fire alarm system, security system, control of the HVAC, the start/stop/monitoring of the power supplies and electrical distribution system, annunciation and communications equipment to emergency personnel, facility occupants, and remote operators.

#### 708.4 Risk Assessment

Risk assessment for critical operations power systems shall be documented and shall be conducted in accordance with 708.4(A) through (C).

Informational Note: Chapter 5 of *NFPA 1600-2010, Standard on Disaster/Emergency Management and Business Continuity Programs*, provides additional guidance concerning risk assessment and hazard analysis.

**(A) Conducting Risk Assessment.** In critical operations power systems, risk assessment shall be performed to identify hazards, the likelihood of their occurrence, and the vulnerability of the electrical system to those hazards.

**(B) Identification of Hazards.** Hazards to be considered at a minimum shall include, but shall not be limited to, the following:

- (1) Naturally occurring hazards (geological, meteorological, and biological)
  - (2) Human-caused events (accidental and intentional)
- [1600:5.3.2]

**(C) Developing Mitigation Strategy.** Based on the results of the risk assessment, a strategy shall be developed and implemented to mitigate the hazards that have not been sufficiently mitigated by the prescriptive requirements of this Code.

### 708.5 Physical Security

Physical security shall be provided for critical operations power systems in accordance with 708.5(A) and (B).

**(A) Risk Assessment.** Based on the results of the risk assessment, a strategy for providing physical security for critical operations power systems shall be developed, documented, and implemented.

**(B) Restricted Access.** Electrical circuits and equipment for critical operations power systems shall be accessible to qualified personnel only.

### 708.6 Testing and Maintenance

**(A) Conduct or Witness Test.** The authority having jurisdiction shall conduct or witness a test of the complete system upon installation and periodically afterward.

**(B) Tested Periodically.** Systems shall be tested periodically on a schedule acceptable to the authority having jurisdiction to ensure the systems are maintained in proper operating condition.

**(C) Maintenance.** The authority having jurisdiction shall require a documented preventive maintenance program for critical operations power systems.

Informational Note: For testing and maintenance procedures, see NFPA 70B-2010, *Recommended Practice for Electrical Equipment Maintenance*.

**(D) Written Record.** A written record shall be kept of such tests and maintenance.

**(E) Testing Under Load.** Means for testing all critical power systems during maximum anticipated load conditions shall be provided.

Informational Note: For testing and maintenance procedures of emergency power supply systems (EPSSs) that are also applicable to COPS, see NFPA 110-2010, *Standard for Emergency and Standby Power Systems*.

### 708.8 Commissioning

**(A) Commissioning Plan.** A commissioning plan shall be developed and documented.

Informational Note: For further information on developing a commissioning program see NFPA 70B-2010, *Recommended Practice for Electrical Equipment Maintenance*.

**(B) Component and System Tests.** The installation of the equipment shall undergo component and system tests to ensure that, when energized, the system will function properly.

**(C) Baseline Test Results.** A set of baseline test results shall be documented for comparison with future periodic maintenance testing to identify equipment deterioration.

**(D) Functional Performance Tests.** A functional performance test program shall be established, documented, and executed upon complete installation of the critical system in order to establish a baseline reference for future performance requirements.

Informational Note: See Informative Annex F for more information on developing and implementing a functional performance test program.

## II. Circuit Wiring and Equipment

### 708.10 Feeder and Branch Circuit Wiring

#### (A) Identification.

**(1) Boxes and Enclosures.** All boxes and enclosures (including transfer switches, generators, and power panels) for critical operations power system circuits shall be permanently marked so they will be readily identified as a component of the system.

**(2) Receptacle Identification.** In a building in which COPS are present with other types of power systems described in other sections in this article, the cover plates for the receptacles or the receptacles themselves supplied from the COPS shall have a distinctive color or marking so as to be readily identifiable.

*Exception: If the COPS supplies power to a DCOA that is a stand-alone building, receptacle cover plates or the receptacles themselves shall not be required to have distinctive marking.*

Section 708.10(A)(2) requires that in a building where a COPS and another type of power system are installed, those receptacles supplied by the COPS or their cover plates must have a distinctive cover or marking. The exception provides that where a COPS supplies power to a Designated Critical Operations Area (DCOA) that is a stand-alone building, the distinctive cover or marking is not required.

**(B) Wiring.** Wiring of two or more COPS circuits supplied from the same source shall be permitted in the same raceway, cable, box, or cabinet. Wiring from a COPS source or COPS source distribution overcurrent protection to critical loads shall be kept entirely independent of all other wiring and equipment.

*Exception: Where the COPS feeder is installed in transfer equipment enclosures.*

**(C) COPS Feeder Wiring Requirements.** COPS feeders shall comply with 708.10(C)(1) through (C)(3).

**(1) Protection Against Physical Damage.** The wiring of the COPS system shall be protected against physical damage. Wiring methods shall be permitted to be installed in accordance with the following:

- (1) Rigid metal conduit, intermediate metal conduit, or Type MI cable.
- (2) Where encased in not less than 50 mm (2 in.) of concrete, any of the following wiring methods shall be permitted:
  - a. Schedule 40 or Schedule 80 rigid polyvinyl chloride conduit (Type PVC)
  - b. Reinforced thermosetting resin conduit (Type RTRC)
  - c. Electrical metallic tubing (Type EMT)
  - d. Flexible nonmetallic or jacketed metallic raceways
  - e. Jacketed metallic cable assemblies listed for installation in concrete
- (3) Where provisions must be made for flexibility at equipment connection, one or more of the following shall also be permitted:
  - a. Flexible metal fittings
  - b. Flexible metal conduit with listed fittings
  - c. Liquidtight flexible metal conduit with listed fittings

**(2) Fire Protection for Feeders.** Feeders shall meet one of the following conditions:

- (1) Be a listed electrical circuit protective system with a minimum 2-hour fire rating

Informational Note: UL guide information for electrical circuit protection systems (FHIT) contains information on proper installation requirements to maintain the fire rating.

- (2) Be protected by a listed fire-rated assembly that has a minimum fire rating of 2 hours
- (3) Be encased in a minimum of 50 mm (2 in.) of concrete

The feeder-circuit wiring covered by 708.10(C)(2) requires a minimum 2-hour fire rating provided by a listed electrical circuit protective system; a listed fire-rated assembly; or be encased in 2 in. of concrete.

It is important to understand the difference between a 2-hour fire rating of an electrical circuit, such as a conduit with wires, and a 2-hour fire resistance rating of a structural member, such as a wall. At the end of a 2-hour fire test on an electrical conduit with wires, the circuit must function electrically; no short circuits, grounds, or opens are permitted.

The circuit and its insulation must be intact and electrically functioning. A wall subjected to a 2-hour fire resistance test must only prevent a fire from passing through or past the wall, without regard to damage to the wall. All fire ratings and fire resistance ratings are based on the assumption that the structural supports for the assembly are not impaired by the effects of the fire.

The *UL Fire Resistance Directory* describes various categories of products that can be used in the fire protection of electrical circuits, including electrical circuit protective systems (FHIT). See the informational note following 708.10(C)(2)(1) for more information. Note that the four-letter code in parentheses, FHIT, is the UL product category guide designation. For information on electrical circuit protective systems, see UL 1724, *Outline of Investigation for Fire Tests for Electrical Circuit Protective Systems*.

**(3) Floodplain Protection.** Where COPS feeders are installed below the level of the 100-year floodplain, the insulated circuit conductors shall be listed for use in a wet location and be installed in a wiring method that is permitted for use in wet locations.

#### **(D) COPS Branch Circuit Wiring.**

(a) *Outside the DCOA.* COPS branch circuits installed outside the DCOA shall comply with the physical and fire protection requirements of 708.10(C)(1) through (C)(3).

(b) *Within the DCOA.* Any of the wiring methods recognized in Chapter 3 of this *Code* shall be permitted within the DCOA.

### **708.11 Branch Circuit and Feeder Distribution Equipment**

**(A) Branch Circuit Distribution Equipment.** COPS branch circuit distribution equipment shall be located within the same DCOA as the branch circuits it supplies.

**(B) Feeder Distribution Equipment.** Equipment for COPS feeder circuits (including transfer equipment, transformers, and panelboards) shall comply with (1) and (2).

- (1) Be located in spaces with a 2-hour fire resistance rating
- (2) Be located above the 100-year floodplain.

### **708.12 Feeders and Branch Circuits Supplied by COPS**

Feeders and branch circuits supplied by the COPS shall supply only equipment specified as required for critical operations use.

### 708.14 Wiring of HVAC, Fire Alarm, Security, Emergency Communications, and Signaling Systems

All conductors or cables shall be installed using any of the metal wiring methods permitted by 708.10(C)(1) and in addition shall comply with 708.14(1) through (8), as applicable.

- (1) All cables for fire alarm, security, signal systems, and emergency communications shall be shielded twisted pair cables.
- (2) Shields of cables for fire alarm, security, signal systems, and emergency communications shall be continuous.
- (3) Optical fiber cables shall be used for connections between two or more buildings on the property and under single management.
- (4) A listed primary protector shall be provided on all communications circuits. Listed secondary protectors shall be provided at the terminals of the communication circuits.
- (5) Conductors for all control circuits rated above 50 volts shall be rated not less than 600 volts.
- (6) Communications, fire alarm, and signaling circuits shall use relays with contact ratings that exceed circuit voltage and current ratings in the controlled circuit.
- (7) All cables for fire alarm, security, and signaling systems shall be riser-rated and shall be a listed 2-hour electrical circuit protective system. Riser emergency communication cables shall be Type CMR-CI or a listed 2-hour electrical circuit protective system.
- (8) Control, monitoring, and power wiring to HVAC systems shall be a listed 2-hour electrical circuit protective system.

## III. Power Sources and Connection

### 708.20 Sources of Power

**(A) General Requirements.** Current supply shall be such that, in the event of failure of the normal supply to the DCOA, critical operations power shall be available within the time required for the application. The supply system for critical operations power, in addition to the normal services to the building and meeting the general requirements of this section, shall be one or more of the types of systems described in 708.20(E) through (H).

Informational Note: Assignment of degree of reliability of the recognized critical operations power system depends on the careful evaluation in accordance with the risk assessment.

**(B) Fire Protection.** Where located within a building, equipment for sources of power as described in 708.20(E) through (H) shall be installed either in spaces fully protected by approved automatic fire suppression systems (sprinklers, carbon dioxide systems, and so forth) or in spaces with a

2-hour fire rating.

**(C) Grounding.** All sources of power shall be grounded as a separately derived source in accordance with 250.30.

*Exception: Where the equipment containing the main bonding jumper or system bonding jumper for the normal source and the feeder wiring to the transfer equipment are installed in accordance with 708.10(C) and 708.11(B).*

**(D) Surge Protection Devices.** Surge protection devices shall be provided at all facility distribution voltage levels.

**(E) Storage Battery.** An automatic battery charging means shall be provided. Batteries shall be compatible with the charger for that particular installation. For a sealed battery, the container shall not be required to be transparent. However, for the lead acid battery that requires water additions, transparent or translucent jars shall be furnished. Automotive-type batteries shall not be used.

**(F) Generator Set.**

**(1) Prime Mover-Driven.** Generator sets driven by a prime mover shall be provided with means for automatically starting the prime mover on failure of the normal service. A time-delay feature permitting a minimum 15-minute setting shall be provided to avoid retransfer in case of short-time reestablishment of the normal source.

**(2) Power for Fuel Transfer Pumps.** Where power is needed for the operation of the fuel transfer pumps to deliver fuel to a generator set day tank, this pump shall be connected to the COPS.

**(3) Dual Supplies.** Prime movers shall not be solely dependent on a public utility gas system for their fuel supply or municipal water supply for their cooling systems. Means shall be provided for automatically transferring from one fuel supply to another where dual fuel supplies are used.

**(4) Battery Power and Dampers.** Where a storage battery is used for control or signal power or as the means of starting the prime mover, it shall be suitable for the purpose and shall be equipped with an automatic charging means independent of the generator set. Where the battery charger is required for the operation of the generator set, it shall be connected to the COPS. Where power is required for the operation of dampers used to ventilate the generator set, the dampers shall be connected to the COPS.

**(5) Outdoor Generator Sets.** Where an outdoor housed generator set is equipped with a readily accessible disconnecting means located within sight of the building or structure supplied, an additional disconnecting means shall not

be required where ungrounded conductors serve or pass through the building or structure.

**(6) Mean for Connecting Portable or Vehicle-Mounted Generator.** Where the COPS is supplied by a single generator, a means to connect a portable or vehicle-mounted generator shall be provided.

**(7) On-Site Fuel Supply.** Where internal combustion engines are used as the prime mover, an on-site fuel supply shall be provided. The on-site fuel supply shall be secured and protected in accordance with the risk assessment.

**(G) Uninterruptible Power Supplies.** Uninterruptible power supplies used as the sole source of power for COPS shall comply with the applicable provisions of 708.20(E) and (F).

**(H) Fuel Cell System.** Installation of a fuel cell system shall meet the requirements of Parts II through VIII of Article 692.

### 708.21 Ventilation

Adequate ventilation shall be provided for the alternate power source for continued operation under maximum anticipated ambient temperatures.

*Informational Note: NFPA 110-2010, Standard for Emergency and Standby Power Systems, and NFPA 111-2010, Standard for Stored Energy Emergency and Standby Power Systems, include additional information on ventilation air for combustion and cooling.*

### 708.22 Capacity of Power Sources

**(A) Capacity and Rating.** A COPS shall have capacity and rating for all loads to be operated simultaneously for continuous operation with variable load for an unlimited number of hours, except for required maintenance of the power source. A portable, temporary, or redundant alternate power source shall be available for use whenever the COPS power source is out of service for maintenance or repair.

**(B) Selective Load Pickup, Load Shedding, and Peak Load Shaving.** The alternate power source shall be permitted to supply COPS emergency, legally required standby, and optional loads where the source has adequate capacity or where automatic selective load pickup and load shedding is provided as needed to ensure adequate power to (1) the COPS and emergency circuits, (2) the legally required standby circuits, and (3) the optional standby circuits, in that order of priority. The alternate power source shall be permitted to be used for peak load shaving, provided these conditions are met.

Peak load-shaving operation shall be permitted for sat-

isfying the test requirement of 708.6(B), provided all other conditions of 708.6 are met.

**(C) Duration of COPS Operation.** The alternate power source shall be capable of operating the COPS for a minimum of 72 hours at full load of DCOA with a steady-state voltage within  $\pm 10$  percent of nominal utilization voltage.

### 708.24 Transfer Equipment

**(A) General.** Transfer equipment, including automatic transfer switches, shall be automatic and identified for emergency use. Transfer equipment shall be designed and installed to prevent the inadvertent interconnection of normal and critical operations sources of supply in any operation of the transfer equipment. Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.

**(B) Bypass Isolation Switches.** Means shall be permitted to bypass and isolate the transfer equipment. Where bypass isolation switches are used, inadvertent parallel operation shall be avoided.

**(C) Automatic Transfer Switches.** Where used with sources that are not inherently synchronized, automatic transfer switches shall comply with (C)(1) and (C)(2).

- (1) Automatic transfer switches shall be listed for emergency use.
- (2) Automatic transfer switches shall be electrically operated and mechanically held.

**(D) Use.** Transfer equipment shall supply only COPS loads.

### 708.30 Branch Circuits Supplied by COPS

Branch circuits supplied by the COPS shall only supply equipment specified as required for critical operations use.

## IV. Overcurrent Protection

### 708.50 Accessibility

The feeder- and branch-circuit overcurrent devices shall be accessible to authorized persons only.

### 708.52 Ground-Fault Protection of Equipment

**(A) Applicability.** The requirements of 708.52 shall apply to critical operations (including multiple occupancy buildings) with critical operation areas.

**(B) Feeders.** Where ground-fault protection is provided for operation of the service disconnecting means or feeder dis-

connecting means as specified by 230.95 or 215.10, an additional step of ground-fault protection shall be provided in all next level feeder disconnecting means downstream toward the load. Such protection shall consist of overcurrent devices and current transformers or other equivalent protective equipment that causes the feeder disconnecting means to open.

The additional levels of ground-fault protection shall not be installed on electrical systems that are not solidly grounded wye systems with greater than 150 volts to ground but not exceeding 600 volts phase-to-phase.

**(C) Testing.** When equipment ground-fault protection is first installed, each level shall be tested to ensure that ground-fault protection is operational.

**Informational Note:** Testing is intended to verify the ground-fault function is operational. The performance test is not intended to verify selectivity in 708.52(D), as this is often coordinated similarly to circuit breakers by reviewing tie and current curves and properly setting the equipment. (Selectivity of fuses and circuit breakers is not performance tested for overload and short circuit.)

**(D) Selectivity.** Ground-fault protection for operation of the service and feeder disconnecting means shall be fully selective such that the feeder device, but not the service device, shall open on ground faults on the load side of the feeder device. A six-cycle minimum separation between the service and feeder ground-fault tripping bands shall be provided. Operating time of the disconnecting devices shall be considered in selecting the time spread between these two bands to achieve 100 percent selectivity.

**Informational Note:** See 230.95, Informational Note No. 4, for transfer of alternate source where ground-fault protection is applied.

### 708.54 Coordination

Critical operations power system(s) overcurrent devices shall be selectively coordinated with all supply side overcurrent protective devices.

## V. System Performance and Analysis

### 708.64 Emergency Operations Plan

A facility with a COPS shall have documented an emergency operations plan. The plan shall consider emergency operations and response, recovery, and continuity of operations.

**Informational Note:** *NFPA 1600-2010, Standard on Disaster/Emergency Management and Business Continuity Programs*, Section 5.7, provides guidance for the development and implementation of emergency plans.

## ARTICLE 720 Circuits and Equipment Operating at Less Than 50 Volts

### Contents

720.1	Scope
720.2	Other Articles
720.3	Hazardous (Classified) Locations
720.4	Conductors
720.5	Lampholders
720.6	Receptacle Rating
720.7	Receptacles Required
720.9	Batteries
720.11	Mechanical Execution of Work

### 720.1 Scope

This article covers installations operating at less than 50 volts, direct current or alternating current.

### 720.2 Other Articles

Direct current or alternating-current installations operating at less than 50 volts, as covered in 411.1 through 411.7; Part VI of Article 517; Part II of Article 551; Parts II and III and 552.60(B) of Article 552; 650.1 through 650.8; 669.1 through 669.9; Parts I and VIII of Article 690; Parts I and III of Article 725; or Parts I and III of Article 760 shall not be required to comply with this article.

Article 411 covers lighting systems operating at 30 volts or less.

### 720.3 Hazardous (Classified) Locations

Installations within the scope of this article and installed in hazardous (classified) locations shall also comply with the appropriate provisions for hazardous (classified) locations in other applicable articles of this *Code*.

Low voltage alone does not render a circuit incapable of igniting flammable atmospheres. Ordinary flashlights using two 1½-volt D-cell batteries, for example, can become a source of ignition in some hazardous (classified) locations.

### 720.4 Conductors

Conductors shall not be smaller than 12 AWG copper or equivalent. Conductors for appliance branch circuits supplying more than one appliance or appliance receptacle shall not be smaller than 10 AWG copper or equivalent.

### 720.5 Lampholders

Standard lampholders that have a rating of not less than 660 watts shall be used.

### 720.6 Receptacle Rating

Receptacles shall have a rating of not less than 15 amperes.

### 720.7 Receptacles Required

Receptacles of not less than 20-ampere rating shall be provided in kitchens, laundries, and other locations where portable appliances are likely to be used.

### 720.9 Batteries

Installations of storage batteries shall comply with 480.1 through 480.4 and 480.8 through 480.10.

### 720.11 Mechanical Execution of Work

Circuits operating at less than 50 volts shall be installed in a neat and workmanlike manner. Cables shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use.

Section 720.11 requires cables to be installed in a manner that is consistent with standard industry practice.

## I. General

### 725.1 Scope

This article covers remote-control, signaling, and power-limited circuits that are not an integral part of a device or appliance.

**Informational Note:** The circuits described herein are characterized by usage and electrical power limitations that differentiate them from electric light and power circuits; therefore, alternative requirements to those of Chapters 1 through 4 are given with regard to minimum wire sizes, ampacity adjustment and correction factors, overcurrent protection, insulation requirements, and wiring methods and materials.

The scope of Article 725 includes such systems as burglar alarm circuits (see Exhibit 725.1), access control circuits, sound circuits, nurse call circuits, intercom circuits, some computer network systems, some control circuits for lighting dimmer systems, and some low-voltage control circuits that originate from listed appliances or from listed computer equipment. Article 760 covers fire alarm circuits and systems. Article 800 covers communications circuits. Article 830 covers network-powered broadband communications circuits.

**EXHIBIT 725.1** Typical burglar alarm system keypad. (Courtesy of NAPCO Security Technologies, Inc.)

The installation requirements for the low-voltage wiring of information technology equipment (electronic data processing and computer equipment) located within the confines

of a room that is constructed according to the requirements of NFPA 75, *Standard for the Protection of Information Technology Equipment*, are not covered by Article 725. Low-voltage wiring within these specially constructed rooms is covered in Article 645.

In addition, if listed computer equipment is interconnected and all the interconnected equipment is in close proximity, the wiring is considered an integral part of the equipment and therefore not subject to the requirements of Article 725. If the wiring leaves the group of equipment to connect to other devices in the same room or elsewhere in the building, the wiring is considered “wiring within buildings” and is subject to the requirements of Article 725.

The wiring methods required by Chapters 1 through 4 of the *Code* apply to remote-control, signaling, and power-limited circuits, except as amended by Article 725 for specified conditions.

A remote-control, signaling, or power-limited circuit is the portion of the wiring system between the load side of the overcurrent device or the power-limited supply and all connected equipment. The circuit is categorized as Class 1, Class 2, or Class 3.

Class 1 circuits are not permitted to exceed 600 volts. In many cases, Class 1 circuits are extensions of power systems and are subject to the requirements of the power systems, except under the following conditions:

1. Conductors size 16 AWG and 18 AWG may be used if properly protected against overcurrent (see 725.43).
2. Where damage to the circuit would introduce a hazard, the circuit must be mechanically protected by a suitable means. [See 725.31(B).]
3. The adjustment factors of 310.15(B)(3) apply only if such conductors carry a continuous load. (See 725.51 for the exact requirements for adjustment factors affecting ampacity.)

Class 1 remote-control circuits are commonly used to operate motor controllers in conjunction with moving equipment or mechanical processes, elevators, conveyors, and other such equipment. Class 1 remote-control circuits may also be used as shunt trip circuits for circuit breakers. Class 1 signaling circuits often operate at 120 volts but are not limited to this value.

Conductors and equipment on the supply side of overcurrent protection, transformers, or current-limiting devices of Class 2 and Class 3 circuits must be installed according to the applicable requirements of Chapter 3. Load-side conductors and equipment must comply with Article 725. Class 2 and Class 3 conductors are required to be separated from and not occupy the same raceways, cable trays, cables, or enclosures as electric light, power, and Class 1 conductors, except as noted in 725.136.

Dry-cell batteries are considered Class 2 power sup-

plies, provided the voltage is 30 volts or less and the capacity is equal to or less than that available from series-connected No. 6 carbon-zinc cells. See 725.121(A)(5).

Circuits originating from thermocouples are categorized Class 2 circuits. Neither dry-cell batteries nor thermocouples are required to be listed.

## 725.2 Definitions

**Abandoned Class 2, Class 3, and PLTC Cable.** Installed Class 2, Class 3, and PLTC cable that is not terminated at equipment and not identified for future use with a tag.

This definition is for use with 725.25, which requires removal of accessible abandoned Class 2, Class 3, and PLTC cables. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, it can affect airflow. Similar requirements can be found in Articles 640, 645, 760, 770, 820, and 830.

**Circuit Integrity (CI) Cable.** Cable(s) used for remote-control, signaling, or power-limited systems that supply critical circuits to ensure survivability for continued circuit operation for a specified time under fire conditions.

This definition is for use with 725.154(H) and 725.179(F), which permit circuit integrity (CI) cables to be used for remote control, signaling, or power-limited systems that supply critical circuits where survivability of the critical system functions under fire conditions is needed. Such cables are likely to be used in systems that are critical to life safety, property protection, or emergency management.

**Class 1 Circuit.** The portion of the wiring system between the load side of the overcurrent device or power-limited supply and the connected equipment.

Informational Note: See 725.41 for voltage and power limitations of Class 1 circuits.

**Class 2 Circuit.** The portion of the wiring system between the load side of a Class 2 power source and the connected equipment. Due to its power limitations, a Class 2 circuit considers safety from a fire initiation standpoint and provides acceptable protection from electric shock.

**Class 3 Circuit.** The portion of the wiring system between the load side of a Class 3 power source and the connected equipment. Due to its power limitations, a Class 3 circuit considers safety from a fire initiation standpoint. Since higher levels of voltage and current than for Class 2 are permitted, additional safeguards are specified to provide protection from an electric shock hazard that could be encountered.

### 725.3 Other Articles

Circuits and equipment shall comply with the articles or sections listed in 725.3(A) through (J). Only those sections of Article 300 referenced in this article shall apply to Class 1, Class 2, and Class 3 circuits.

**(A) Number and Size of Conductors in Raceway.** Section 300.17.

**(B) Spread of Fire or Products of Combustion.** Installation of Class 1, Class 2, and Class 3 circuits shall comply with 300.21.

**(C) Ducts, Plenums, and Other Air-Handling Spaces.** Class 1, Class 2, and Class 3 circuits installed in ducts, plenums, or other space used for environmental air shall comply with 300.22.

*Exception:* As permitted in 725.154(A).

See the commentary following 300.22(B), 300.22(C), and informational note to 725.179(A), for information on wiring in ducts, plenums, and other air-handling spaces.

**(D) Hazardous (Classified) Locations.** Articles 500 through 516 and Article 517, Part IV, where installed in hazardous (classified) locations.

**(E) Cable Trays.** Article 392, where installed in cable tray.

**(F) Motor Control Circuits.** Article 430, Part VI, where tapped from the load side of the motor branch-circuit protective device(s) as specified in 430.72(A).

**(G) Instrumentation Tray Cable.** See Article 727.

**(H) Raceways Exposed to Different Temperatures.** Installations shall comply with 300.7(A).

Section 725.3(H) addresses installations where raceways are exposed to different temperatures. Condensation often forms in conduit exposed to nonconditioned and conditioned spaces. Section 725.3(H) brings the requirements of 300.7(A) into Article 725.

**(I) Vertical Support for Fire-Rated Cables and Conductors.** Vertical installations of circuit integrity (CI) cables and conductors installed in a raceway or conductors and cables of electrical circuit protective systems shall be installed in accordance with 300.19.

Support requirements for fire-rated cable are critical and contained in 300.19(B). The strength of cables and conductors decrease with heat and may break if not properly supported and this could adversely impact the operation of signaling systems that are important to public safety.

**(J) Bushing.** A bushing shall be installed where cables emerge from raceway used for mechanical support or protection in accordance with 300.15(C).

Conduits and other raceways are often used for mechanical support or protection of cables. A bushing is needed to protect cables from damage.

### 725.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels, including suspended ceiling panels.

An excess accumulation of wires and cables can limit access to electrical equipment by preventing the removal of access panels. To service, rearrange, or install electrical equipment, the worker must have an accessible work space for working safely on energized equipment. See 300.11(A), which permits the use of support wires and approved fittings that are independent of the suspended ceiling support wires. (See Exhibit 725.2; also see 725.24.)

### 725.24 Mechanical Execution of Work

Class 1, Class 2, and Class 3 circuits shall be installed in a neat and workmanlike manner. Cables and conductors installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be supported by straps, staples, hangers, cable ties, or similar fittings designed and installed so as not to damage the cable. The installation shall also comply with 300.4(D).

Section 725.24 makes it clear that the *Code* requires cables to be installed in a neat and workmanlike manner, by providing definitive requirements for workmanship. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable should be carefully evaluated to ensure that activities and

**EXHIBIT 725.2** *Incorrect installation of conductors and cables (upper diagram), which can prevent access to equipment or cables. Correct method is shown in the lower diagram.*

processes within the building do not cause damage to the cable. (See 725.143 and Exhibit 725.2.)

The reference to 300.4(D) calls attention to the hazards to which cables are exposed where they are installed on framing members. Such cables are required to be installed in a manner that protects them from nail or screw penetration. This section permits attachment to baseboards and non-load-bearing walls, which are not structural components.

### 725.25 Abandoned Cables

The accessible portion of abandoned Class 2, Class 3, and PLTC cables shall be removed. Where cables are identified for future use with a tag, the tag shall be of sufficient durability to withstand the environment involved.

Section 725.25 requires the removal of accessible abandoned cable. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, it can affect airflow. Similar requirements can be found in Articles 640, 645, 760, 770, 800, 820, and 830. See the definition of *abandoned Class 2, Class 3, and PLTC cable* in 725.2.

### 725.30 Class 1, Class 2, and Class 3 Circuit Identification

Class 1, Class 2, and Class 3 circuits shall be identified at terminal and junction locations in a manner that prevents un-

intentional interference with other circuits during testing and servicing.

### 725.31 Safety-Control Equipment

**(A) Remote-Control Circuits.** Remote-control circuits for safety-control equipment shall be classified as Class 1 if the failure of the equipment to operate introduces a direct fire or life hazard. Room thermostats, water temperature regulating devices, and similar controls used in conjunction with electrically controlled household heating and air conditioning shall not be considered safety-control equipment.

The remote-control circuits to safety-control devices are required to be classified as Class 1 if failure of the safety-control circuit could cause a direct fire or life hazard. One example of the direct link between a failure and the initiation of a fire hazard is a boiler explosion caused by failure of the low-water cutoff circuit. See Exhibit 725.3.

**EXHIBIT 725.3** *Typical installation of an automatic oil burner unit for a boiler employing a safety shutdown circuit requiring re-classification according to the requirements of 725.31(A).*

Generally, signaling systems intended to provide notification of a hazard, such as a nurse call system, do not fit this category. These systems do not have a direct link to the initiation of fire or the initiation of a life hazard but, rather, serve as the reporting or warning link of a hazard initiated by some other (indirect) cause.

**(B) Physical Protection.** Where damage to remote-control circuits of safety-control equipment would introduce a hazard, as covered in 725.31(A), all conductors of such remote-

control circuits shall be installed in rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, electrical metallic tubing, Type MI cable, Type MC cable, or be otherwise suitably protected from physical damage.

### 725.35 Class 1, Class 2, and Class 3 Circuit Requirements

A remote-control, signaling, or power-limited circuit shall comply with the following parts of this article:

- (1) Class 1 Circuits: Parts I and II
- (2) Class 2 and Class 3 Circuits: Parts I and III

## II. Class 1 Circuits

### 725.41 Class 1 Circuit Classifications and Power Source Requirements

Class 1 circuits shall be classified as either Class 1 power-limited circuits where they comply with the power limitations of 725.41(A) or as Class 1 remote-control and signaling circuits where they are used for remote-control or signaling purposes and comply with the power limitations of 725.41(B).

**(A) Class 1 Power-Limited Circuits.** These circuits shall be supplied from a source that has a rated output of not more than 30 volts and 1000 volt-amperes.

**(1) Class 1 Transformers.** Transformers used to supply power-limited Class 1 circuits shall comply with the applicable sections within Parts I and II of Article 450.

**(2) Other Class 1 Power Sources.** Power sources other than transformers shall be protected by overcurrent devices rated at not more than 167 percent of the volt-ampere rating of the source divided by the rated voltage. The overcurrent devices shall not be interchangeable with overcurrent devices of higher ratings. The overcurrent device shall be permitted to be an integral part of the power supply.

To comply with the 1000 volt-ampere limitation of 725.41(A), the maximum output ( $VA_{max}$ ) of power sources other than transformers shall be limited to 2500 volt-amperes, and the product of the maximum current ( $I_{max}$ ) and maximum voltage ( $V_{max}$ ) shall not exceed 10,000 volt-amperes. These ratings shall be determined with any overcurrent-protective device bypassed.

$VA_{max}$  is the maximum volt-ampere output after one minute of operation regardless of load and with overcurrent protection bypassed, if used. Current-limiting impedance shall not be bypassed when determining  $VA_{max}$ .

$I_{max}$  is the maximum output current under any noncapacitive load, including short circuit, and with overcurrent protection bypassed, if used. Current-limiting impedance should not be bypassed when determining  $I_{max}$ . Where a current-limiting impedance, listed for the purpose or as part

of a listed product, is used in combination with a stored energy source, for example, storage battery, to limit the output current,  $I_{max}$  limits apply after 5 seconds.

$V_{max}$  is the maximum output voltage regardless of load with rated input applied.

**(B) Class 1 Remote-Control and Signaling Circuits.** These circuits shall not exceed 600 volts. The power output of the source shall not be required to be limited.

Often, remote-control and signaling circuits that do not meet the requirements of Class 2 or Class 3 circuits are classed as Class 1 circuits by default. For example, a listed nurse call system may contain a power supply with an output of 500 watts at 24 volts. Because this power supply exceeds the maximum permitted output of a Class 2 power supply and the output terminals are not marked to indicate the equipment as suitable for a Class 2 power supply, the output circuit wiring is classified as Class 1 and subject to all the Class 1 circuit requirements.

### 725.43 Class 1 Circuit Overcurrent Protection

Overcurrent protection for conductors 14 AWG and larger shall be provided in accordance with the conductor ampacity, without applying the ampacity adjustment and correction factors of 310.15 to the ampacity calculation. Overcurrent protection shall not exceed 7 amperes for 18 AWG conductors and 10 amperes for 16 AWG.

*Exception: Where other articles of this Code permit or require other overcurrent protection.*

Informational Note: For example, see 430.72 for motors, 610.53 for cranes and hoists, and 517.74(B) and 660.9 for X-ray equipment.

### 725.45 Class 1 Circuit Overcurrent Device Location

Overcurrent devices shall be located as specified in 725.45(A), (B), (C), (D), or (E).

**(A) Point of Supply.** Overcurrent devices shall be located at the point where the conductor to be protected receives its supply.

**(B) Feeder Taps.** Class 1 circuit conductors shall be permitted to be tapped, without overcurrent protection at the tap, where the overcurrent device protecting the circuit conductor is sized to protect the tap conductor.

**(C) Branch-Circuit Taps.** Class 1 circuit conductors 14 AWG and larger that are tapped from the load side of the overcurrent protective device(s) of a controlled light and

power circuit shall require only short-circuit and ground-fault protection and shall be permitted to be protected by the branch-circuit overcurrent protective device(s) where the rating of the protective device(s) is not more than 300 percent of the ampacity of the Class 1 circuit conductor.

Section 725.45(C) correlates with 240.4(G).

**(D) Primary Side of Transformer.** Class 1 circuit conductors supplied by the secondary of a single-phase transformer having only a 2-wire (single-voltage) secondary shall be permitted to be protected by overcurrent protection provided on the primary side of the transformer, provided this protection is in accordance with 450.3 and does not exceed the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio. Transformer secondary conductors other than 2-wire shall not be considered to be protected by the primary overcurrent protection.

Section 725.45(D) correlates with 240.4(F) and 430.72(B), Exception No. 2.

**(E) Input Side of Electronic Power Source.** Class 1 circuit conductors supplied by the output of a single-phase, listed electronic power source, other than a transformer, having only a 2-wire (single-voltage) output for connection to Class 1 circuits shall be permitted to be protected by overcurrent protection provided on the input side of the electronic power source, provided this protection does not exceed the value determined by multiplying the Class 1 circuit conductor ampacity by the output-to-input voltage ratio. Electronic power source outputs, other than 2-wire (single voltage), shall not be considered to be protected by the primary overcurrent protection.

Electronic power supplies that do not supply energy directly through the use of transformers are covered by 725.45(E), which permits overcurrent protection for the Class 1 circuit conductors to be installed on the input side of the power source rather than the output side.

## 725.46 Class 1 Circuit Wiring Methods

Class 1 circuits shall be installed in accordance with Part I of Article 300 and with the wiring methods from the appropriate articles in Chapter 3.

*Exception No. 1: The provisions of 725.48 through 725.51 shall be permitted to apply in installations of Class 1 circuits.*

*Exception No. 2: Methods permitted or required by other articles of this Code shall apply to installations of Class 1 circuits.*

## 725.48 Conductors of Different Circuits in the Same Cable, Cable Tray, Enclosure, or Raceway

Class 1 circuits shall be permitted to be installed with other circuits as specified in 725.48(A) and (B).

**(A) Two or More Class 1 Circuits.** Class 1 circuits shall be permitted to occupy the same cable, cable tray, enclosure, or raceway without regard to whether the individual circuits are alternating current or direct current, provided all conductors are insulated for the maximum voltage of any conductor in the cable, cable tray, enclosure, or raceway.

**(B) Class 1 Circuits with Power-Supply Circuits.** Class 1 circuits shall be permitted to be installed with power-supply conductors as specified in 725.48(B)(1) through (B)(4).

**(1) In a Cable, Enclosure, or Raceway.** Class 1 circuits and power-supply circuits shall be permitted to occupy the same cable, enclosure, or raceway only where the equipment powered is functionally associated.

**(2) In Factory- or Field-Assembled Control Centers.** Class 1 circuits and power-supply circuits shall be permitted to be installed in factory- or field-assembled control centers.

**(3) In a Manhole.** Class 1 circuits and power-supply circuits shall be permitted to be installed as underground conductors in a manhole in accordance with one of the following:

- (1) The power-supply or Class 1 circuit conductors are in a metal-enclosed cable or Type UF cable.
- (2) The conductors are permanently separated from the power-supply conductors by a continuous firmly fixed nonconductor, such as flexible tubing, in addition to the insulation on the wire.
- (3) The conductors are permanently and effectively separated from the power supply conductors and securely fastened to racks, insulators, or other approved supports.

Section 725.48(B)(3) permits Class 1 power-limited circuit conductors to be installed in manholes with wiring of non-power-limited systems where suitable separation provides the same degree of protection as required for the following:

1. Class 2 and Class 3 power-limited circuits in 725.136
2. Communications circuits in 800.133(A)

3. Radio/television antennas and lead-in conductors in 810.18
4. CATV conductors in 820.133(A)

**(4) In Cable Trays.** Installations in cable trays shall comply with 725.48(B)(4)(1) or (B)(4)(2).

- (1) Class 1 circuit conductors and power-supply conductors not functionally associated with the Class 1 circuit conductors shall be separated by a solid fixed barrier of a material compatible with the cable tray.
- (2) Class 1 circuit conductors and power-supply conductors not functionally associated with the Class 1 circuit conductors shall be permitted to be installed in a cable tray without barriers where all of the conductors are installed with separate multiconductor Type AC, Type MC, Type MI, or Type TC cables and all the conductors in the cables are insulated at 600 volts.

Section 725.48(B)(4) offers two choices for cable tray installations. One choice is to separate Class 1 conductors and power circuit conductors of equipment that is not functionally associated with a solid fixed barrier. The other choice is to run the circuits in separate multiconductor cables using the specified types where all of the conductors are insulated at 600 volts.

### 725.49 Class 1 Circuit Conductors

**(A) Sizes and Use.** Conductors of sizes 18 AWG and 16 AWG shall be permitted to be used, provided they supply loads that do not exceed the ampacities given in 402.5 and are installed in a raceway, an approved enclosure, or a listed cable. Conductors larger than 16 AWG shall not supply loads greater than the ampacities given in 310.15. Flexible cords shall comply with Article 400.

**(B) Insulation.** Insulation on conductors shall be **rated** for 600 volts. Conductors larger than 16 AWG shall comply with Article 310. Conductors in sizes 18 AWG and 16 AWG shall be Type FFH-2, KF-2, KFF-2, PAF, PAFF, PF, PFF, PGF, PGFF, PTF, PTFF, RFH-2, RFHH-2, RFHH-3, SF-2, SFF-2, TF, TFF, TFFN, TFN, ZF, or ZFF. Conductors with other types and thicknesses of insulation shall be permitted if listed for Class 1 circuit use.

Section 725.49 requires all Class 1 circuit conductors to be rated at 600 volts. This effectively requires Class 1 circuits to be wired using the wiring methods found in Chapter 3 or the use of conductors specifically listed for Class 1 circuit use.

### 725.51 Number of Conductors in Cable Trays and Raceway, and Ampacity Adjustment

**(A) Class 1 Circuit Conductors.** Where only Class 1 circuit conductors are in a raceway, the number of conductors shall be determined in accordance with 300.17. The **ampacity adjustment** factors given in 310.15(B)(3)(a) shall apply only if such conductors carry continuous loads in excess of 10 percent of the ampacity of each conductor.

**(B) Power-Supply Conductors and Class 1 Circuit Conductors.** Where power-supply conductors and Class 1 circuit conductors are permitted in a raceway in accordance with 725.48, the number of conductors shall be determined in accordance with 300.17. The **ampacity adjustment** factors given in 310.15(B)(3)(a) shall apply as follows:

- (1) To all conductors where the Class 1 circuit conductors carry continuous loads in excess of 10 percent of the ampacity of each conductor and where the total number of conductors is more than three
- (2) To the power-supply conductors only, where the Class 1 circuit conductors do not carry continuous loads in excess of 10 percent of the ampacity of each conductor and where the number of power-supply conductors is more than three

In previous editions of the *Code*, the term *derating factors* was used with reference to 310.15(B)(3)(a), which provides the factors by which conductor ampacity is adjusted to account for the mutual heating effect on conductor ampacity where a raceway or cable contains more than three conductors. The term *ampacity adjustment factors* is the correct terminology used in conjunction with the requirements of 310.15(B)(3)(a).

**(C) Class 1 Circuit Conductors in Cable Trays.** Where Class 1 circuit conductors are installed in cable trays, they shall comply with the provisions of 392.22 and 392.80(A).

### 725.52 Circuits Extending Beyond One Building

Class 1 circuits that extend aurally beyond one building shall also meet the requirements of Article 225.

## III. Class 2 and Class 3 Circuits

### 725.121 Power Sources for Class 2 and Class 3 Circuits

**(A) Power Source.** The power source for a Class 2 or a Class 3 circuit shall be as specified in 725.121(A)(1), (A)(2), (A)(3), (A)(4), or (A)(5):

Informational Note No. 1: Figure 725.121 illustrates the relationships between Class 2 or Class 3 power sources, their supply, and the Class 2 or Class 3 circuits.

Informational Note No. 2: Table 11(A) and Table 11(B) in Chapter 9 provide the requirements for listed Class 2 and Class 3 power sources.

- (1) A listed Class 2 or Class 3 transformer
- (2) A listed Class 2 or Class 3 power supply
- (3) Other listed equipment marked to identify the Class 2 or Class 3 power source

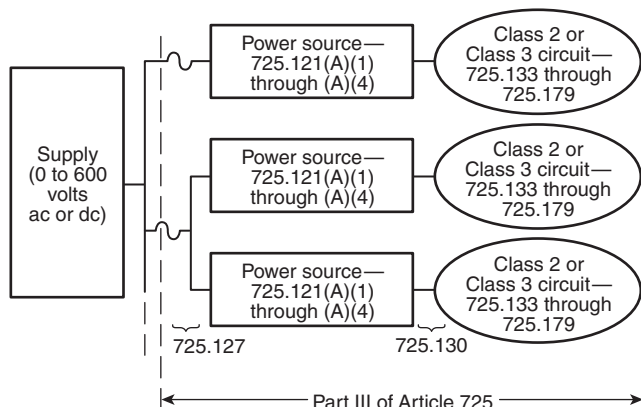

*Exception No. 1 to (3): Thermocouples shall not require listing as a Class 2 power source*

*Exception No. 2 to (3): Limited power circuits of listed equipment where these circuits have energy levels rated at or below the limits established in Chapter 9, Table 11(A) and Table 11(B).*

Informational Note: Examples of other listed equipment are as follows:

- (1) A circuit card listed for use as a Class 2 or Class 3 power source where used as part of a listed assembly
  - (2) A current-limiting impedance, listed for the purpose, or part of a listed product, used in conjunction with a non-power-limited transformer or a stored energy source, for example, storage battery, to limit the output current
  - (3) A thermocouple
  - (4) Limited voltage/current or limited impedance secondary communications circuits of listed industrial control equipment
- (4) Listed information technology (computer) equipment limited-power circuits.

Informational Note: One way to determine applicable requirements for listing of information technology (computer) equipment is to refer to UL 60950-1-2003, *Standard for Safety of Information Technology Equipment*. Typically such circuits are used to interconnect information technology equipment for the purpose of exchanging information (data).

**FIGURE 725.121** Class 2 and Class 3 Circuits.

- (5) A dry cell battery shall be considered an inherently limited Class 2 power source, provided the voltage is 30 volts or less and the capacity is equal to or less than that available from series connected No. 6 carbon zinc cells.

**(B) Interconnection of Power Sources.** Class 2 or Class 3 power sources shall not have the output connections paralleled or otherwise interconnected unless listed for such interconnection.

Except for dry-cell batteries and thermocouples, 725.121(B) requires listed power sources for Class 2 and Class 3 circuits.

### 725.124 Circuit Marking

The equipment supplying the circuits shall be durably marked where plainly visible to indicate each circuit that is a Class 2 or Class 3 circuit.

Section 725.124 requires equipment supplying Class 2 and Class 3 circuits to be marked to clearly identify the point of connection for such circuits. This section requires the equipment to be marked, rather than the individual raceways, cables, and fittings.

### 725.127 Wiring Methods on Supply Side of the Class 2 or Class 3 Power Source

Conductors and equipment on the supply side of the power source shall be installed in accordance with the appropriate requirements of Chapters 1 through 4. Transformers or other devices supplied from electric light or power circuits shall be protected by an overcurrent device rated not over 20 amperes.

*Exception: The input leads of a transformer or other power source supplying Class 2 and Class 3 circuits shall be permitted to be smaller than 14 AWG, but not smaller than 18 AWG if they are not over 12 in. (305 mm) long and if they have insulation that complies with 725.49(B).*

Listed Class 2 and Class 3 transformers must be protected by an overcurrent device not exceeding 20 amperes, unless the transformers are fed from circuits other than power or lighting.

### 725.130 Wiring Methods and Materials on Load Side of the Class 2 or Class 3 Power Source

Class 2 and Class 3 circuits on the load side of the power source shall be permitted to be installed using wiring meth-

ods and materials in accordance with either 725.130(A) or (B).

**(A) Class 1 Wiring Methods and Materials.** Installation shall be in accordance with 725.46.

*Exception No. 1: The ampacity adjustment factors given in 310.15(B)(3)(a) shall not apply.*

See the commentary following 725.51(B) for a discussion of ampacity adjustment factors.

*Exception No. 2: Class 2 and Class 3 circuits shall be permitted to be reclassified and installed as Class 1 circuits if the Class 2 and Class 3 markings required in 725.124 are eliminated and the entire circuit is installed using the wiring methods and materials in accordance with Part II, Class 1 circuits.*

Informational Note: Class 2 and Class 3 circuits reclassified and installed as Class 1 circuits are no longer Class 2 or Class 3 circuits, regardless of the continued connection to a Class 2 or Class 3 power source.

**(B) Class 2 and Class 3 Wiring Methods.** Conductors on the load side of the power source shall be insulated at not less than the requirements of 725.179 and shall be installed in accordance with 725.133 and 725.154.

*Exception No. 1: As provided for in 620.21 for elevators and similar equipment.*

*Exception No. 2: Other wiring methods and materials installed in accordance with the requirements of 725.3 shall be permitted to extend or replace the conductors and cables described in 725.179 and permitted by 725.130(B).*

*Exception No. 3: Bare Class 2 conductors shall be permitted as part of a listed intrusion protection system where installed in accordance with the listing instructions for the system.*

Section 725.130 permits the following two distinct wiring methods for circuits connected to Class 2 or Class 3 power sources:

- Class 1 wiring methods
- Class 2 and Class 3 wiring methods

Where it is necessary to locate Class 2 or Class 3 circuits inside the same cable or raceway as a Class 1 circuit, 725.130(A), Exception No. 2, permits a Class 2 or Class 3 circuit to be reclassified and installed as Class 1, providing that the Class 2 or Class 3 marking is removed, that overcur-

rent protection is provided in accordance with 725.43, and that the reclassified circuit maintains separation from other Class 2 and Class 3 circuits in accordance with 725.136.

### 725.133 Installation of Conductors and Equipment in Cables, Compartments, Cable Trays, Enclosures, Manholes, Outlet Boxes, Device Boxes, and Raceways for Class 2 and Class 3 Circuits

Conductors and equipment for Class 2 and Class 3 circuits shall be installed in accordance with 725.136 through 725.143.

### 725.136 Separation from Electric Light, Power, Class 1, Non-Power-Limited Fire Alarm Circuit Conductors, and Medium-Power Network-Powered Broadband Communications Cables

**(A) General.** Cables and conductors of Class 2 and Class 3 circuits shall not be placed in any cable, cable tray, compartment, enclosure, manhole, outlet box, device box, raceway, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm circuits, and medium-power network-powered broadband communications circuits unless permitted by 725.136(B) through (I).

Section 725.136(A) specifically includes cables of Class 2 and Class 3 circuits. Jackets of listed Class 2 and Class 3 cables do not have sufficient construction specifications to permit them to be installed with electric light, power, Class 1, non-power-limited fire alarm circuits, and medium-power network-powered broadband communications cables. Failure of the cable insulation due to a fault could lead to hazardous voltages being imposed on the Class 2 or Class 3 circuit conductors.

**(B) Separated by Barriers.** Class 2 and Class 3 circuits shall be permitted to be installed together with the conductors of electric light, power, Class 1, non-power-limited fire alarm and medium power network-powered broadband communications circuits where they are separated by a barrier.

**(C) Raceways Within Enclosures.** In enclosures, Class 2 and Class 3 circuits shall be permitted to be installed in a raceway to separate them from Class 1, non-power-limited fire alarm and medium-power network-powered broadband communications circuits.

**(D) Associated Systems Within Enclosures.** Class 2 and Class 3 circuit conductors in compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted

to be installed with electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits, and where (1) or (2) applies:

- (1) The electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuit conductors are routed to maintain a minimum of 6 mm (0.25 in.) separation from the conductors and cables of Class 2 and Class 3 circuits.
- (2) The circuit conductors operate at 150 volts or less to ground and also comply with one of the following:
  - a. The Class 2 and Class 3 circuits are installed using Type CL3, CL3R, or CL3P or permitted substitute cables, provided these Class 3 cable conductors extending beyond the jacket are separated by a minimum of 6 mm (0.25 in.) or by a nonconductive sleeve or nonconductive barrier from all other conductors.
  - b. The Class 2 and Class 3 circuit conductors are installed as a Class 1 circuit in accordance with 725.41.

Power circuit and Class 2 circuit conductors are permitted in the same motor-starter enclosure, where the Class 2 circuit source is the secondary of a control transformer in the same motor-starter enclosure. In such an installation, the Class 2 conductor insulation is not required to have the same voltage rating as the insulation on the power conductors in the same enclosure.

**(E) Enclosures with Single Opening.** Class 2 and Class 3 circuit conductors entering compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with Class 1, non-power-limited fire alarm and medium-power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits. Where Class 2 and Class 3 circuit conductors must enter an enclosure that is provided with a single opening, they shall be permitted to enter through a single fitting (such as a tee), provided the conductors are separated from the conductors of the other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing.

**(F) Manholes.** Underground Class 2 and Class 3 circuit conductors in a manhole shall be permitted to be installed with Class 1, non-power-limited fire alarm and medium-power network-powered broadband communications circuits where one of the following conditions is met:

- (1) The electric light, power, Class 1, non-power-limited fire alarm and medium-power network-powered broadband communications circuit conductors are in a metal-enclosed cable or Type UF cable.
- (2) The Class 2 and Class 3 circuit conductors are permanently and effectively separated from the conductors of other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing, in addition to the insulation or covering on the wire.
- (3) The Class 2 and Class 3 circuit conductors are permanently and effectively separated from conductors of the other circuits and securely fastened to racks, insulators, or other approved supports.

Section 725.136(F) permits the installation of Class 2 and Class 3 power-limited circuit conductors in manholes that have wiring for electric light, power, Class 1, and non-power-limited fire alarm circuit systems, and from medium-power network-powered broadband communications cables where suitable separation provides the same degree of protection as required in 725.136(A). [See the commentary following 725.48(B)(3).]

**(G) Cable Trays.** Class 2 and Class 3 circuit conductors shall be permitted to be installed in cable trays, where the conductors of the electric light, Class 1, and non-power-limited fire alarm circuits are separated by a solid fixed barrier of a material compatible with the cable tray or where the Class 2 or Class 3 circuits are installed in Type MC cable.

Section 725.136(G) permits the mixing of circuits in some cable tray applications where a physical barrier within the tray provides the necessary separation, without the need for a separate tray. Type MC cable also provides suitable physical protection so that jacket damage that results in faults between circuits is unlikely.

**(H) In Hoistways.** In hoistways, Class 2 or Class 3 circuit conductors shall be installed in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit, or electrical metallic tubing. For elevators or similar equipment, these conductors shall be permitted to be installed as provided in 620.21.

**(I) Other Applications.** For other applications, conductors of Class 2 and Class 3 circuits shall be separated by at least 50 mm (2 in.) from conductors of any electric light, power, Class 1 non-power-limited fire alarm or medium power network-powered broadband communications circuits unless one of the following conditions is met:

- (1) Either (a) all of the electric light, power, Class 1, non-power-limited fire alarm and medium-power network-powered broadband communications circuit conductors or (b) all of the Class 2 and Class 3 circuit conductors are in a raceway or in metal-sheathed, metal-clad, non-metallic-sheathed, or Type UF cables.
- (2) All of the electric light, power, Class 1 non-power-limited fire alarm, and medium-power network-powered broadband communications circuit conductors are permanently separated from all of the Class 2 and Class 3 circuit conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the conductors.

### 725.139 Installation of Conductors of Different Circuits in the Same Cable, Enclosure, Cable Tray, or Raceway

**(A) Two or More Class 2 Circuits.** Conductors of two or more Class 2 circuits shall be permitted within the same cable, enclosure, or raceway.

**(B) Two or More Class 3 Circuits.** Conductors of two or more Class 3 circuits shall be permitted within the same cable, enclosure, or raceway.

**(C) Class 2 Circuits with Class 3 Circuits.** Conductors of one or more Class 2 circuits shall be permitted within the same cable, enclosure, or raceway with conductors of Class 3 circuits, provided the insulation of the Class 2 circuit conductors in the cable, enclosure, or raceway is at least that required for Class 3 circuits.

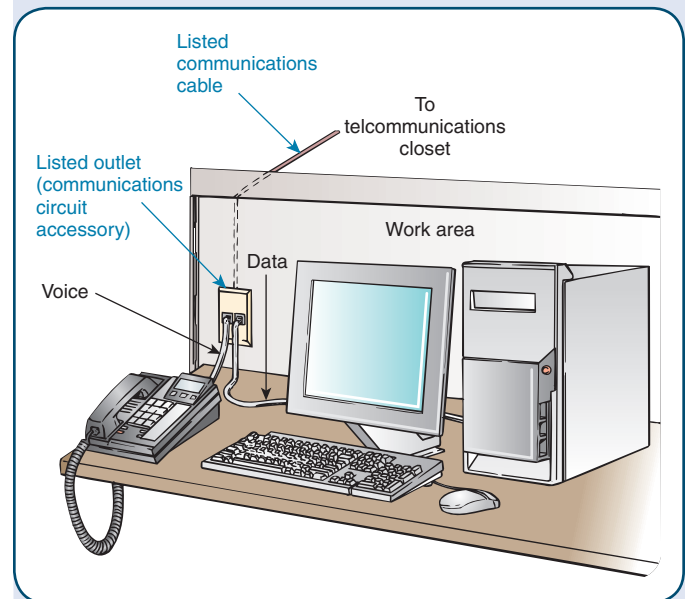

#### **(D) Class 2 and Class 3 Circuits with Communications Circuits.**

**(1) Classified as Communications Circuits.** Class 2 and Class 3 circuit conductors shall be permitted in the same cable with communications circuits, in which case the Class 2 and Class 3 circuits shall be classified as communications circuits and shall be installed in accordance with the requirements of Article 800. The cables shall be listed as communications cables.

**(2) Composite Cables.** Cables constructed of individually listed Class 2, Class 3, and communications cables under a common jacket shall be permitted to be classified as communications cables. The fire resistance rating of the composite cable shall be determined by the performance of the composite cable.

To minimize the amount of cabling in a typical office environment, 725.139(D) permits telephone and data circuits to

be in the same listed communications cable. Exhibit 725.4 illustrates such an arrangement.

**EXHIBIT 725.4** Telephone and data circuits in the same cable.

**(E) Class 2 or Class 3 Cables with Other Circuit Cables.** Jacketed cables of Class 2 or Class 3 circuits shall be permitted in the same enclosure, cable tray, or raceway with jacketed cables of any of the following:

- (1) Power-limited fire alarm systems in compliance with Article 760
- (2) Nonconductive and conductive optical fiber cables in compliance with Article 770
- (3) Communications circuits in compliance with Article 800
- (4) Community antenna television and radio distribution systems in compliance with Article 820
- (5) Low-power, network-powered broadband communications in compliance with Article 830

**(F) Class 2 or Class 3 Conductors or Cables and Audio System Circuits.** Audio system circuits described in 640.9(C), and installed using Class 2 or Class 3 wiring methods in compliance with 725.133 and 725.154, shall not be permitted to be installed in the same cable or raceway with Class 2 or Class 3 conductors or cables.

### 725.141 Installation of Circuit Conductors Extending Beyond One Building

Where Class 2 or Class 3 circuit conductors extend beyond one building and are run so as to be subject to accidental

contact with electric light or power conductors operating over 300 volts to ground, or are exposed to lightning on interbuilding circuits on the same premises, the requirements of the following shall also apply:

- (1) Sections 800.44, 800.50, 800.53, 800.93, 800.100, 800.170(A), and 800.170(B) for other than coaxial conductors
- (2) Sections 820.44, 820.93, and 820.100 for coaxial conductors

### 725.143 Support of Conductors

Class 2 or Class 3 circuit conductors shall not be strapped, taped, or attached by any means to the exterior of any conduit or other raceway as a means of support. These conductors shall be permitted to be installed as permitted by 300.11(B)(2).

See the commentary following 725.24 for more information on the support of conductors.

### 725.154 Applications of Listed Class 2, Class 3, and PLTC Cables

Class 2, Class 3, and PLTC cables shall comply with any of the requirements described in 725.154(A) through (I).

**(A) Plenums.** Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type CL2P or CL3P. Listed wires and cables installed in compliance with 300.22 shall be permitted. Listed plenum signaling raceways shall be permitted to be installed in other spaces used for environmental air as described in 300.22(C). Only Type CL2P or CL3P cable shall be permitted to be installed in these raceways.

**(B) Riser.** Cables installed in risers shall be as described in any of (B)(1), (B)(2), or (B)(3):

- (1) Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type CL2R or CL3R. Floor penetrations requiring Type CL2R or CL3R shall contain only cables suitable for riser or plenum use. Listed riser signaling raceways and listed plenum signaling raceways shall be permitted to be installed in vertical riser runs in a shaft from floor to floor. Only Type CL2R, CL3R, CL2P, or CL3P cables shall be permitted to be installed in these raceways.
- (2) Other cables as covered in Table 725.154(G) and other listed wiring methods as covered in Chapter 3 shall be installed in metal raceways, or located in a fireproof shaft having firestops at each floor.

- (3) Type CL2, CL3, CL2X, and CL3X cables shall be permitted in one- and two-family dwellings. Listed general-purpose signaling raceways shall be permitted for use with Type CL2, CL3, CL2X, and CL3X cables.

Informational Note: See 300.21 for firestop requirements for floor penetrations.

**(C) Cable Trays.** Cables installed in cable trays outdoors shall be Type PLTC. Cables installed in cable trays indoors shall be Types PLTC, CL3P, CL3R, CL3, CL2P, CL2R, and CL2.

Listed general-purpose signaling raceways, listed riser signaling raceways, and listed plenum signaling raceways shall be permitted for use with cable trays.

Informational Note: See 800.154 for cables permitted in cable trays.

**(D) Industrial Establishments.** In industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation, Type PLTC cable shall be permitted in accordance with either (1) or (2):

Section 725.154(D) permits use of two special versions of Type PLTC cable as exposed wiring between a cable tray and utilization equipment in industrial establishments. One type has a metallic sheath. The other type is labeled as PLTC-ER. The latter type is required to meet the same crush and impact resistance requirements as Type MC cable. This allowance offers the installer an alternative to Type MC cable. Both versions of Type PLTC cable must also be continuously supported and mechanically protected from damage. The cable must be secured at intervals not exceeding 6 ft.

- (1) Where the cable is not subject to physical damage, Type PLTC cable that complies with the crush and impact requirements of Type MC cable and is identified as PLTC-ER for such use shall be permitted to be exposed between the cable tray and the utilization equipment or device. The cable shall be continuously supported and protected against physical damage using mechanical protection such as dedicated struts, angles, or channels. The cable shall be supported and secured at intervals not exceeding 1.8 m (6 ft).

Type PLTC cable that complies with the crush and impact requirements of Type MC cable is identified as PLTC-ER and is permitted to be run between a cable tray and utilization equipment or a device.

(2) Type PLTC cable, with a metallic sheath or armor in accordance with 725.179(E), shall be permitted to be installed exposed. The cable shall be continuously supported and protected against physical damage using mechanical protection such as dedicated struts, angles, or channels. The cable shall be secured at intervals not exceeding 1.8 m (6 ft).

**(E) Other Wiring Within Buildings.** Cables installed in building locations other than those covered in 725.154(A) through (D) shall be as described in any of (E)(1) through (E)(6).

**(1) General.** Type CL2 or CL3 shall be permitted.

**(2) In Raceways or Other Wiring Methods.** Type CL2X or CL3X shall be permitted to be installed in a raceway or in accordance with other wiring methods covered in Chapter 3.

**(3) Nonconcealed Spaces.** Type CL2X and Type CL3X cables shall be permitted to be installed in nonconcealed spaces where the exposed length of cable does not exceed 3 m (10 ft).

**(4) One- and Two-Family Dwellings.** Type CL2X cables less than 6 mm (0.25 in.) in diameter and Type CL3X cables less than 6 mm (0.25 in.) in diameter shall be permitted to be installed in one- and two-family dwellings.

**(5) Multifamily Dwellings.** Type CL2X cables less than 6 mm (0.25 in.) in diameter and Type CL3X cables less than 6 mm (0.25 in.) in diameter shall be permitted to be installed in nonconcealed spaces in multifamily dwellings.

**(6) Under Carpets.** Type CMUC undercarpet communications wires and cables shall be permitted to be installed under carpet.

**(F) Cross-Connect Arrays.** Type CL2 or CL3 conductors or cables shall be used for cross-connect arrays.

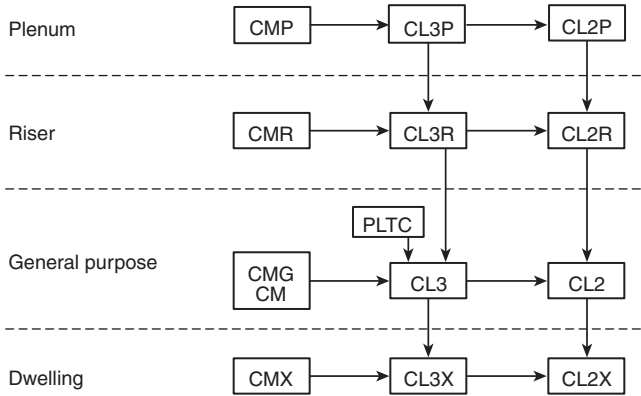

Cross-connect arrays and patch panels located within building spaces must be cross wired, jumpered, or interconnected using listed cables.

**(G) Class 2 and Class 3 Cable Substitutions.** The substitutions for Class 2 and Class 3 cables listed in Table 725.154(G) and illustrated in Figure 725.154(G) shall be permitted. Where substitute cables are installed, the wiring requirements of Article 725, Parts I and III, shall apply.

Informational Note: For information on Types CMP, CMR, CM, and CMX, see 800.179.

TABLE 725.154(G) Cable Substitutions

Cable Type	Permitted Substitutions
CL3P	CMP
CL2P	CMP, CL3P
CL3R	CMP, CL3P, CMR
CL2R	CMP, CL3P, CL2P, CMR, CL3R
PLTC	
CL3	CMP, CL3P, CMR, CL3R, CMG, CM, PLTC
CL2	CMP, CL3P, CL2P, CMR, CL3R, CL2R, CMG, CM, PLTC, CL3
CL3X	CMP, CL3P, CMR, CL3R, CMG, CM, PLTC, CL3, CMX
CL2X	CMP, CL3P, CL2P, CMR, CL3R, CL2R, CMG, CM, PLTC, CL3, CL2, CMX, CL3X

Type CM—Communications wires and cables  
Type CL2 and CL3—Class 2 and Class 3 remote-control, signaling, and power-limited cables  
Type PLTC—Power-limited tray cable

[A]→[B] Cable A shall be permitted to be used in place of Cable B.

FIGURE 725.154(G) Cable Substitution Hierarchy

**(H) Class 2, Class 3, PLTC Circuit Integrity (CI) Cable or Electrical Circuit Protective System.** Circuit integrity (CI) cable or a listed electrical circuit protective system shall be permitted for use in remote control, signaling, or power-limited systems that supply critical circuits to ensure survivability for continued circuit operation for a specified time under fire conditions.

Section 725.154(H) permits the use of circuit integrity cable for applications where continuity of the operations of critical circuits is needed during a fire. Such circuits could be essential to fire-fighting operations or could be circuits whose interruption could cause a more dangerous condition to occur. An example is a smoke removal system.

**(I) Thermocouple Circuits.** Conductors in Type PLTC cables used for Class 2 thermocouple circuits shall be permitted to be any of the materials used for thermocouple extension wire.

## IV. Listing Requirements

### 725.179 Listing and Marking of Class 2, Class 3, and Type PLTC Cables

Class 2, Class 3, and Type PLTC cables and nonmetallic signaling raceways installed as wiring methods within buildings shall be listed as being resistant to the spread of fire and other criteria in accordance with 725.179(A) through (K) and shall be marked in accordance with 725.179(L).

**(A) Types CL2P and CL3P.** Types CL2P and CL3P plenum cable shall be listed as being suitable for use in ducts, plenums, and other space for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

NFPA 262, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*, is a test method for electrical wires and cables that are to be installed without raceways in plenums and other spaces used for environmental air. NFPA 262 was originally developed as UL 910, *Test for Flame Propagation and Smoke-Density Values for Electrical and Optical-Fiber Cables Used in Spaces Transporting Environmental Air*, which is an adaptation of the Steiner Tunnel test (NFPA 255/ASTM E84/UL 723, *Standard Method of Test of Surface Burning Characteristics of Building Materials*).

The test is conducted in a 25-ft-long horizontal duct lined with insulating masonry faced with a row of refractory fire brick. One side of the duct is provided with a row of double-paned observation windows that permit monitoring of the progress of the test. The end of the chamber designated the fire end is provided with two gas burners that deliver flames upward to engulf the test specimen. The burners are positioned on each side of the centerline of the furnace so that flame is evenly distributed across the sample. Test specimens are installed in a cable tray that is 24 ft long.

Smoke output is measured in a metal vent pipe at the vent end of the furnace, which is opposite the fire end.

Where smoke passes through the vent pipe, it passes between a light source and a photocell. The output signal of the photocell is directly proportional to the amount of light received.

The cable specimens are exposed to a fire source with an output of 294,000 Btu/hr for a period of 20 minutes. A graph is plotted that illustrates the flame distance beyond 4½ ft (measured from the end of the flame delivered by the burners) versus the time taken for the duration of the test. This graph is plotted against a flame spread curve representative of a red oak specimen. A graph is also plotted for optical density versus time for the sample. Optical density is calculated as follows:

$$\text{Optical density} = \log_{10} \frac{T_0}{T}$$

where:

$T_0$  = initial light transmission

$T$  = light transmission during test

NFPA 262 does not list pass/fail criteria. The criteria for acceptance of a given application are given in the appropriate sections of the *Code*. See the informational notes that follow 725.179(A), 760.179(D), 770.179(A), 800.182(A), and 820.179(A).

A Class 2 or Class 3 cable that has passed the requirements of this test may be used in ducts, plenums, or other air-handling spaces. In addition, such cable may be used anywhere in a building where Class 2 or Class 3 cable is permitted. [See Table 725.154(G).]

**(B) Types CL2R and CL3R.** Types CL2R and CL3R riser cables shall be marked as Type CL2R or CL3R, respectively, and be listed as suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2002, *Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

In the fire test covered in UL 1666, *Test for Flame Propagation Height of Electrical and Optical-Fiber Cables Installed Vertically in Shafts*, cables are arranged in a simulated vertical shaft and subjected to an ignition source. The shaft is a 19-ft-high concrete shaft divided into two compartments at the 12-ft level. There is a 1-ft by 2-ft opening between the two compartments. The ignition source is a burner with a heat output rate of 495,000 Btu/hr.

The individual cable lengths are suspended from a sup-

port system on the second floor and held in place just below the support system and at the first-floor slot.

The support frame consists of a steel bar located on the second floor above the slot opening. The individual cable lengths are suspended from the support frame by one of the following methods:

1. The cables are draped over the support frame.
2. The cables are arranged in a clamping device that is suspended from the support frame by two hooks.
3. In the case of large-diameter cables, each individual cable is placed in a wire-mesh grip. Each grip is attached to a hook that is suspended from the support frame.

To pass, cables must not propagate flame to the top of the 12-ft-high compartment during the 30-minute test.

**(C) Types CL2 and CL3.** Types CL2 and CL3 cables shall be marked as Type CL2 or CL3, respectively, and be listed as suitable for general-purpose use, with the exception of risers, ducts, plenums, and other space used for environmental air, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

The UL vertical tray flame test determines whether cables installed in a ladder-type cable tray will propagate fire from a given exposure. The test flame is supplied by a strip or ribbon-type propane gas burner.

The cables are installed in a steel ladder-type cable tray that is 12 in. wide, 3 in. deep, and 8 ft long. Cables are installed in the tray spaced half a diameter apart, filling 75 percent of the tray width. A burner supplying 70,000 Btu/hr (20.32 kW/hr) is positioned 18 in. above the bottom of the tray, midway between two rungs. The burner flame is applied to the samples for a period of 20 minutes. The samples are considered to have passed the test if flame has not propagated to the top of the cable tray by the test’s conclusion. A cable that passes this testing may be listed as a Type CL2 or Type CL3 cable. [See also the commentary following the informational note to 725.179(D).]

**(D) Types CL2X and CL3X.** Types CL2X and CL3X limited-use cables shall be marked as Type CL2X or CL3X respectively, and be listed as being suitable for use in dwellings and for use in raceway and shall also be listed as being resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical wire) flame test in ANSI/UL 1581-2001, *Reference Standard for Electrical Wires, Cables and Flexible Cords*.

UL 1581, *Reference Standard for Electrical Wires, Cables and Flexible Cords*, contains basic requirements for conductors, insulation, jackets, and other coverings and the methods of sample preparation, specimen selection and conditioning, and measurements and calculations required in UL 44, *Thermoset-Insulated Wires and Cables*; UL 83, *Thermoplastic-Insulated Wires and Cables*; and UL 62, *Flexible Cord and Fixture Wire*. The flame test methods of these standards include the vertical wire flame test (VW-1) and the vertical tray flame test. [Also see the commentary following the informational note to 725.179(C).]

The VW-1 test is a small-scale test of the flammability of insulating material. It uses a single specimen, secured in a vertical position in a three-sided metal enclosure that has a layer of untreated surgical cotton on the bottom. For thermoplastic- or rubber-insulated wire and cable, the specimen used is an 18-in. insulated 14 AWG copper or 12 AWG aluminum conductor. A small kraft-paper indicator flag is attached to the specimen near its top. A flame is impinging 10 in. below the bottom of the flag for a period of 15 seconds. The flame is removed for 15 seconds and then reapplied for 15 seconds. This procedure is repeated for five 15-second flame applications. The specimen is considered to be capable of propagating fire if one of the following occurs:

1. More than 25 percent of the indicator flag is burned away or charred.
2. Flaming or glowing particles are emitted that ignite the surgical cotton.
3. The specimen continues to flame longer than 60 seconds after removal of the burner.

A sample that passes this test may be listed as Type CL2X or Type CL3X, suitable for use as a limited-use, power-limited cable. This cable may be used in one-family, two-family, and multifamily dwellings.

**(E) Type PLTC.** Type PLTC nonmetallic-sheathed, power-limited tray cable shall be listed as being suitable for cable trays and shall consist of a factory assembly of two or more insulated conductors under a nonmetallic jacket. The insulated conductors shall be 22 AWG through 12 AWG. The conductor material shall be copper (solid or stranded).

Insulation on conductors shall be rated for 300 volts. The cable core shall be either (1) two or more parallel conductors, (2) one or more group assemblies of twisted or parallel conductors, or (3) a combination thereof. A metallic shield or a metallized foil shield with drain wire(s) shall be permitted to be applied either over the cable core, over groups of conductors, or both. The cable shall be listed as being resistant to the spread of fire. The outer jacket shall be a sunlight- and moisture-resistant nonmetallic material. Type PLTC cable used in a wet location shall be listed for use in wet locations or have a moisture-impervious metal sheath.

*Exception No. 1: Where a smooth metallic sheath, continuous corrugated metallic sheath, or interlocking tape armor is applied over the nonmetallic jacket, an overall nonmetallic jacket shall not be required. On metallic-sheathed cable without an overall nonmetallic jacket, the information required in 310.120 shall be located on the nonmetallic jacket under the sheath.*

*Exception No. 2: Conductors in PLTC cables used for Class 2 thermocouple circuits shall be permitted to be any of the materials used for thermocouple extension wire.*

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

**(F) Circuit Integrity (CI) Cable or Electrical Circuit Protective System.** Cables used for survivability of critical circuits shall be listed as circuit integrity (CI) cable. Cables specified in 725.154(A), (B), (D)(1), and (E), and used for circuit integrity, shall have the additional classification using the suffix “-CI”. Cables that are part of a listed electrical circuit protective system shall be considered to meet the requirements of survivability.

Informational Note: One method of defining *circuit integrity* is by establishing a minimum 2-hour fire resistance rating when tested in accordance with UL 2196-2002, *Standard for Tests of Fire Resistive Cables*.

Section 725.179(F) permits the use of circuit integrity (CI) cable for applications where continuity of the operations of critical circuits is needed during a fire. Such circuits could be essential to fire-fighting operations or could be circuits whose interruption could cause a more dangerous condi-

tion to occur. A smoke removal system is an example of where it may be necessary to use circuit integrity cables for control circuits to ensure that the dampers will operate during a fire.

**(G) Class 2 and Class 3 Cable Voltage Ratings.** Class 2 cables shall have a voltage rating of not less than 150 volts. Class 3 cables shall have a voltage rating of not less than 300 volts.

**(H) Class 3 Single Conductors.** Class 3 single conductors used as other wiring within buildings shall not be smaller than 18 AWG and shall be Type CL3. Conductor types described in 725.49(B) that are also listed as Type CL3 shall be permitted.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

Section 725.179(H) clarifies that Class 3 single conductors must also be resistant to the spread of fire.

**(I) Plenum Signaling Raceways.** Plenum signaling raceways shall be listed as having adequate fire-resistant and low smoke-producing characteristics.

Section 725.179(I) recognizes listed nonmetallic signaling raceways for use in plenums. Similar raceways are currently recognized for optical fiber and communications cables in Articles 770 and 800, respectively. Raceways listed for plenums must pass fire tests similar to those required of cables listed for plenums.

**(J) Riser Signaling Raceways.** Riser signaling raceways shall be listed as having adequate fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the raceways pass the requirements of the Test for Flame Propagation (Riser) in UL 2024, *Standard for Optical Fiber Cable Raceway*.

Section 725.179(J) recognizes listed nonmetallic signaling raceways for use in risers. Similar raceways are currently recognized for optical fiber and communications cables in Articles 770 and 800, respectively. Raceways listed for risers must pass fire tests similar to those required of cables listed for risers.

**(K) General-Purpose Signaling Raceways.** General-purpose signaling raceways shall be listed as being resistant to the spread of fire.

Informational Note: One method of defining resistance to the spread of fire is that the raceways pass the requirements of the Vertical-Tray Flame Test (General use) in UL 2024, *Standard for Optical Fiber Cable Raceway*.

Section 725.179(K) recognizes listed nonmetallic signaling raceways for use in general-purpose applications. Similar raceways are currently recognized for optical fiber and communications cables in Articles 770 and 800, respectively. Raceways listed for general-purpose applications must pass fire tests similar to those required of cables listed for general-purpose applications.

**(L) Marking.** Cables shall be marked in accordance with 310.120(A)(2), (A)(3), (A)(4), and (A)(5) and Table 725.179. Voltage ratings shall not be marked on the cables.

Informational Note: Voltage markings on cables may be misinterpreted to suggest that the cables may be suitable for Class 1 electric light and power applications.

*Exception: Voltage markings shall be permitted where the cable has multiple listings and a voltage marking is required for one or more of the listings.*

**TABLE 725.179 Cable Marking**

Cable Marking	Type
CL3P	Class 3 plenum cable
CL2P	Class 2 plenum cable
CL3R	Class 3 riser cable
CL2R	Class 2 riser cable
PLTC	Power-limited tray cable
CL3	Class 3 cable
CL2	Class 2 cable
CL3X	Class 3 cable, limited use
CL2X	Class 2 cable, limited use

Informational Note: Class 2 and Class 3 cable types are listed in descending order of fire resistance rating, and Class 3 cables are listed above Class 2 cables because Class 3 cables can substitute for Class 2 cables.

## ARTICLE 727

### Instrumentation Tray Cable: Type ITC

#### Contents

- 727.1 Scope
- 727.2 Definition
- 727.3 Other Articles
- 727.4 Uses Permitted
- 727.5 Uses Not Permitted
- 727.6 Construction
- 727.7 Marking
- 727.8 Allowable Ampacity
- 727.9 Overcurrent Protection
- 727.10 Bends

#### 727.1 Scope

This article covers the use, installation, and construction specifications of instrumentation tray cable for application to instrumentation and control circuits operating at 150 volts or less and 5 amperes or less.

Article 727 permits an alternate wiring method for circuits that do not exceed 5 amperes and 150 volts. Instrument tray cable is particularly suited for instrumentation circuits in industrial establishments where qualified persons perform service and maintenance.

#### 727.2 Definition

**Type ITC Instrumentation Tray Cable.** A factory assembly of two or more insulated conductors, with or without a grounding conductor(s), enclosed in a nonmetallic sheath.

#### 727.3 Other Articles

In addition to the provisions of this article, installation of Type ITC cable shall comply with other applicable articles of this *Code*.

#### 727.4 Uses Permitted

Type ITC cable shall be permitted to be used as follows in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons service the installation:

- (1) In cable trays.
- (2) In raceways.
- (3) In hazardous locations as permitted in 501.10, 502.10, 503.10, 504.20, 504.30, 504.80, and 505.15.
- (4) Enclosed in a smooth metallic sheath, continuous corrugated metallic sheath, or interlocking tape armor

applied over the nonmetallic sheath in accordance with 727.6. The cable shall be supported and secured at intervals not exceeding 1.8 m (6 ft).

- (5) Cable, without a metallic sheath or armor, that complies with the crush and impact requirements of Type MC cable and is identified for such use with the marking *ITC-ER* shall be permitted to be installed exposed. The cable shall be continuously supported and protected against physical damage using mechanical protection such as dedicated struts, angles, or channels. The cable shall be secured at intervals not exceeding 1.8 m (6 ft).
- (6) As aerial cable on a messenger.
- (7) Direct buried where identified for the use.
- (8) Under raised floors in rooms containing industrial process control equipment and rack rooms where arranged to prevent damage to the cable.
- (9) Under raised floors in information technology equipment rooms in accordance with 645.5(E)(5)(c).

### 727.5 Uses Not Permitted

Type ITC cable shall not be installed on circuits operating at more than 150 volts or more than 5 amperes.

Installation of Type ITC cable with other cables shall be subject to the stated provisions of the specific articles for the other cables. Where the governing articles do not contain stated provisions for installation with Type ITC cable, the installation of Type ITC cable with the other cables shall not be permitted.

Type ITC cable shall not be installed with power, lighting, Class 1 circuits that are not power limited, or non-power-limited circuits.

*Exception No. 1: Where terminated within equipment or junction boxes and separations are maintained by insulating barriers or other means.*

*Exception No. 2: Where a metallic sheath or armor is applied over the nonmetallic sheath of the Type ITC cable.*

### 727.6 Construction

The insulated conductors of Type ITC cable shall be in sizes 22 AWG through 12 AWG. The conductor material shall be copper or thermocouple alloy. Insulation on the conductors shall be rated for 300 volts. Shielding shall be permitted.

The cable shall be listed as being resistant to the spread of fire. The outer jacket shall be sunlight and moisture resistant.

Where a smooth metallic sheath, continuous corrugated metallic sheath, or interlocking tape armor is applied over the nonmetallic sheath, an overall nonmetallic jacket shall not be required.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray

Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

### 727.7 Marking

The cable shall be marked in accordance with 310.120(A)(2), (A)(3), (A)(4), and (A)(5). Voltage ratings shall not be marked on the cable.

### 727.8 Allowable Ampacity

The allowable ampacity of the conductors shall be 5 amperes, except for 22 AWG conductors, which shall have an allowable ampacity of 3 amperes.

### 727.9 Overcurrent Protection

Overcurrent protection shall not exceed 5 amperes for 20 AWG and larger conductors, and 3 amperes for 22 AWG conductors.

### 727.10 Bends

Bends in Type ITC cables shall be made so as not to damage the cable.

## I. General

### 760.1 Scope

This article covers the installation of wiring and equipment of fire alarm systems including all circuits controlled and powered by the fire alarm system.

Informational Note No. 1: Fire alarm systems include fire detection and alarm notification, guard's tour, sprinkler waterflow, and sprinkler supervisory systems. Circuits controlled and powered by the fire alarm system include circuits for the control of building systems safety functions, elevator capture, elevator shutdown, door release, smoke doors and damper control, fire doors and damper control and fan shutdown, but only where these circuits are powered by and controlled by the fire alarm system. For further information on the installation and monitoring for integrity requirements for fire alarm systems, refer to the *NFPA 72-2010, National Fire Alarm and Signaling Code*.

Informational Note No. 2: Class 1, 2, and 3 circuits are defined in Article 725.

Article 760 covers only circuits that are powered and controlled by the fire alarm system, including fire safety features such as smoke door control, damper control, fan shutdown, and elevator recall. Circuits powered and controlled by other building systems such as heating, ventilating, and air conditioning (HVAC); security; lighting controls; and time recording are covered by Article 725.

Article 760 covers the wiring between the devices and equipment required by *NFPA 72, National Fire Alarm and Signaling Code*. *NFPA 72* provides the requirements for the selection, installation, performance, use, and testing and maintenance of fire alarm system components. The provision for whether a specific occupancy is required to have a fire alarm system is found in *NFPA 101, Life Safety Code*, or other local codes.

Examples of fire alarm equipment and devices are shown in Exhibits 760.1 and 760.2. The installation of these system components is covered by *NFPA 72*, but the circuit wiring associated with these components must be installed in accordance with the requirements of Article 760. Single- and multiple-station smoke alarms, such as those commonly installed in dwelling units, are supplied through 120-volt branch circuits rather than through a non-power-limited or power-limited fire alarm signaling circuit that is powered and controlled by a fire alarm control panel. Branch circuits supplying power to single- and multiple-station smoke alarms are not subject to the requirements of Article 760.

*NFPA 72* requires that all wiring, cable, and equipment be in accordance with *NFPA 70, National Electrical Code*, and specifically with Article 760. Additionally, *NFPA 72* requires all equipment to be listed for its intended purpose.

*NFPA 1221, Standard for the Installation, Maintenance, and Use of Emergency Services Communications*

**EXHIBIT 760.1** Typical fire alarm control unit. (Courtesy of the International Association of Electrical Inspectors)

**EXHIBIT 760.2** Typical spot-type smoke detector.

*Systems*, covers the installation, performance, operation, and maintenance of public emergency services' communications systems and facilities. These facilities include public reporting, dispatching, telephone, and two-way and microwave radio systems, all of which fulfill two principal functions: the receipt of fire alarms or other emergency calls from the public and the retransmission of these alarms and emergency calls to fire companies and other appropriate agencies.

### 760.2 Definitions

**Abandoned Fire Alarm Cable.** Installed fire alarm cable that is not terminated at equipment other than a connector and not identified for future use with a tag.

This definition is for use with 760.25, which requires removal of accessible abandoned fire alarm cable. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, it can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 770, 800, 820, and 830.

**Fire Alarm Circuit.** The portion of the wiring system between the load side of the overcurrent device or the power-limited supply and the connected equipment of all circuits powered and controlled by the fire alarm system. Fire alarm circuits are classified as either non–power-limited or power-limited.

**Fire Alarm Circuit Integrity (CI) Cable.** Cable used in fire alarm systems to ensure continued operation of critical circuits during a specified time under fire conditions.

**Non–Power-Limited Fire Alarm Circuit (NPLFA).** A fire alarm circuit powered by a source that complies with 760.41 and 760.43.

**Power-Limited Fire Alarm Circuit (PLFA).** A fire alarm circuit powered by a source that complies with 760.121.

### 760.3 Other Articles

Circuits and equipment shall comply with 760.3(A) through (K). Only those sections of Article 300 referenced in this article shall apply to fire alarm systems.

**(A) Spread of Fire or Products of Combustion.** See 300.21.

**(B) Ducts, Plenums, and Other Air-Handling Spaces.** Section 300.22, where installed in ducts or plenums or other spaces used for environmental air.

*Exception: As permitted in 760.53(B)(1) and (B)(2) and 760.154(A).*

See the commentary following 300.22(B) and (C) for more information on wiring installed in ducts, plenums, or other air-handling spaces.

**(C) Hazardous (Classified) Locations.** Articles 500 through 516 and Article 517, Part IV, where installed in hazardous (classified) locations.

**(D) Corrosive, Damp, or Wet Locations.** Sections 110.11, 300.6, and 310.10(G), where installed in corrosive, damp, or wet locations.

Section 760.3(D) requires cables and equipment used in wet or damp locations, high ambient temperature areas, or cor-

rosive locations to be identified as suitable for the particular use. Underground installations are considered wet locations.

**(E) Building Control Circuits.** Article 725, where building control circuits (e.g., elevator capture, fan shutdown) are associated with the fire alarm system.

**(F) Optical Fiber Cables.** Where optical fiber cables are utilized for fire alarm circuits, the cables shall be installed in accordance with Article 770.

**(G) Installation of Conductors with Other Systems.** Installations shall comply with 300.8.

**(H) Raceways or Sleeves Exposed to Different Temperatures.** Installations shall comply with 300.7(A).

Section 760.3(H) addresses installations where raceways or sleeves are exposed to different temperatures. Condensation often forms in conduit exposed to nonconditioned and conditioned spaces. Section 760.3(H) brings the requirements of 300.7(A) into Article 760.

**(I) Vertical Support for Fire Rated Cables and Conductors.** Vertical installations of circuit integrity (CI) cables and conductors installed in a raceway or conductors and cables of electrical circuit protective systems shall be installed in accordance with 300.19.

Support requirements for fire-rated cable are critical and contained in 300.19(B). The strength of cables and conductors decrease with heat and may break if not properly supported. Support of vertical runs of fire-rated cables helps ensure continued performance if the cable is exposed directly to a fire or to high temperatures caused by a fire.

**(J) Number and Size of Cables and Conductors in Raceway.** Installations shall comply with 300.17.

Section 760.3(J) references the requirements of 300.17 for the number and size of conductors in raceways. Compliance with the raceway fill requirement protects conductors against abrasion or other physical damage resulting from too many conductors being pulled through a raceway. Because of the critical life safety function of the fire alarm system conductors, protecting the conductors against damage increases overall system reliability. In addition, system modifications are facilitated by providing the ability to install and withdraw conductors without causing damage to the conductors

that remain in the raceway. This requirement applies to non-power-limited and power-limited fire alarm circuit conductors.

**(K) Bushing.** A bushing shall be installed where cables emerge from raceway used for mechanical support or protection in accordance with 300.15(C).

Conduits and other raceways are often used for mechanical support or protection of cables. A bushing is needed to protect cables from damage.

### 760.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of conductors and cables that prevents removal of panels, including suspended ceiling panels.

An excess accumulation of wires and cables can limit access to equipment by preventing the removal of access panels. See Exhibit 760.3.

**EXHIBIT 760.3** Incorrect installation of conductors and cables (upper diagram), which can prevent access to equipment or cables. Correct method is shown in lower diagram.

### 760.24 Mechanical Execution of Work

Fire alarm circuits shall be installed in a neat workmanlike manner. Cables and conductors installed exposed on the sur-

face of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be supported by straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also comply with 300.4(D).

Section 760.24 provides definitive requirements for workmanship. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable should be carefully evaluated to ensure that activities and processes within the building do not cause damage to the cable.

The reference to 300.4(D) calls attention to the hazards to which cables are exposed where they are installed on framing members. Such cables are required to be installed in a manner that protects them from nail or screw penetration. This section permits attachment to baseboards and non-load-bearing walls, which are not structural components.

### 760.25 Abandoned Cables

The accessible portion of abandoned fire alarm cables shall be removed. Where cables are identified for future use with a tag, the tag shall be of sufficient durability to withstand the environment involved.

Section 760.25 requires the removal of accessible abandoned fire alarm cable. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, it can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 770, 800, 820, and 830. See the definition of *abandoned fire alarm cable* in 760.2.

### 760.30 Fire Alarm Circuit Identification

Fire alarm circuits shall be identified at terminal and junction locations in a manner that helps to prevent unintentional signals on fire alarm system circuit(s) during testing and servicing of other systems.

### 760.32 Fire Alarm Circuits Extending Beyond One Building

Power-limited fire alarm circuits that extend beyond one building and run outdoors either shall meet the installation requirements of Parts II, III, and IV of Article 800 or shall meet the installation requirements of Part I of Article 300. Non-power-limited fire alarm circuits that extend beyond one building and run outdoors shall meet the installation re-

quirements of Part I of Article 300 and the applicable sections of Part I of Article 225.

### 760.35 Fire Alarm Circuit Requirements

Fire alarm circuits shall comply with 760.35(A) and (B).

**(A) Non-Power-Limited Fire Alarm (NPLFA) Circuits.** See Parts I and II.

**(B) Power-Limited Fire Alarm (PLFA) Circuits.** See Parts I and III.

Exact power source limitations for power-limited fire alarm circuits used by testing laboratories are found in Chapter 9, Tables 12(A) and 12(B). Table 12(A) covers alternating-current source limitations, and Table 12(B) covers direct-current source limitations.

## II. Non-Power-Limited Fire Alarm (NPLFA) Circuits

### 760.41 NPLFA Circuit Power Source Requirements

**(A) Power Source.** The power source of non-power-limited fire alarm circuits shall comply with Chapters 1 through 4, and the output voltage shall be not more than 600 volts, nominal. The fire alarm circuit disconnect shall be permitted to be secured in the “on” position.

The last sentence of 760.41(A) permits the fire alarm circuit disconnect to be secured in the “on” position. This provides correlation with *NFPA 72, National Fire Alarm and Signaling Code*, which requires the circuit disconnecting means to be accessible only to authorized personnel. By limiting access, there is a decreased chance that the power to the fire alarm system is turned off.

**(B) Branch Circuit.** The branch circuit supplying the fire alarm equipment(s) shall supply no other loads. The location of the branch-circuit overcurrent protective device shall be permanently identified at the fire alarm control unit. The circuit disconnecting means shall have red identification, shall be accessible only to qualified personnel, and shall be identified as “FIRE ALARM CIRCUIT.” The red identification shall not damage the overcurrent protective devices or obscure the manufacturer’s markings. This branch circuit shall not be supplied through ground-fault circuit interrupters or arc-fault circuit-interrupters.

Informational Note: See 210.8(A)(5), Exception, for receptacles in dwelling-unit unfinished basements that supply power for fire alarm systems.

The requirements of 760.41(B) correlate with the requirements of *NFPA 72*. *NFPA 72* requires that the power to the fire alarm system be supplied from a branch circuit dedicated to the fire alarm system. The dedicated circuit may be used to power other control units and power supplies that are part of the system, but this power circuit cannot be used to power other equipment, such as phone switches, music-on-hold, fax machines, computer stations, and other equipment that is not directly associated with the fire alarm system functions. Further, *NFPA 72* requires the location of the branch circuit disconnecting means to be permanently identified at the control unit. The circuit disconnecting means is required to be identified as “FIRE ALARM CIRCUIT” and have a red marking.

Exhibit 760.4 illustrates a plug-in power supply for a fire alarm control unit. The other half of the duplex receptacle shown is permitted only to supply other fire alarm related equipment.

**EXHIBIT 760.4** Duplex receptacle supplied by circuit dedicated to fire alarm equipment. (Courtesy of Merton Bunker)

In order to minimize interruption of the normal ac power, 760.41(B) prohibits supplying non-power-limited fire alarm equipment with a branch circuit having the enhanced level of shock protection afforded by a ground-fault

circuit interrupter or arcing fault protection afforded by an arc-fault circuit interrupter. The branch circuit is required to have overcurrent protection in accordance with the general provisions of Articles 210 and 240, is required to supply only fire alarm equipment, and is subject to the requirements of 210.12(A), Exception No. 3, if the outlet supplying the fire alarm equipment is installed in an area of a dwelling unit that is subject to the AFCI protection requirements of 210.12(A).

The AFCI protection requirements in Article 210 apply to outlets supplying single- or multiple-station smoke alarms where the smoke alarm outlet is located in an area covered by the requirements of 210.12(A). Single- and multiple-station smoke alarms are supplied by a branch circuit covered by the requirements of Article 210, not through a non-power-limited fire alarm circuit powered by the fire alarm control panel. In new construction, single- and multiple-station smoke alarms are required by *NFPA 72, National Fire Alarm and Signaling Code*, to have a backup battery that will supply power in the event that the branch circuit power is interrupted due to the operation of an AFCI device.

### 760.43 NPLFA Circuit Overcurrent Protection

Overcurrent protection for conductors 14 AWG and larger shall be provided in accordance with the conductor ampacity without applying the ampacity adjustment and correction factors of 310.15 to the ampacity calculation. Overcurrent protection shall not exceed 7 amperes for 18 AWG conductors and 10 amperes for 16 AWG conductors.

*Exception:* Where other articles of this Code permit or require other overcurrent protection.

### 760.45 NPLFA Circuit Overcurrent Device Location

Overcurrent devices shall be located at the point where the conductor to be protected receives its supply.

*Exception No. 1:* Where the overcurrent device protecting the larger conductor also protects the smaller conductor.

*Exception No. 2:* Transformer secondary conductors. Non-power-limited fire alarm circuit conductors supplied by the secondary of a single-phase transformer that has only a 2-wire (single-voltage) secondary shall be permitted to be protected by overcurrent protection provided by the primary (supply) side of the transformer, provided the protection is in accordance with 450.3 and does not exceed the value determined by multiplying the secondary conductor ampacity by the secondary-to-primary transformer voltage ratio. Transformer secondary conductors other than 2-wire shall not be considered to be protected by the primary overcurrent protection.

*Exception No. 3:* Electronic power source output conductors. Non-power-limited circuit conductors supplied by the output of a single-phase, listed electronic power source, other than a transformer, having only a 2-wire (single-voltage) output for connection to non-power-limited circuits shall be permitted to be protected by overcurrent protection provided on the input side of the electronic power source, provided this protection does not exceed the value determined by multiplying the non-power-limited circuit conductor ampacity by the output-to-input voltage ratio. Electronic power source outputs, other than 2-wire (single voltage), connected to non-power-limited circuits shall not be considered to be protected by overcurrent protection on the input of the electronic power source.

**Informational Note:** A single-phase, listed electronic power supply whose output supplies a 2-wire (single-voltage) circuit is an example of a non-power-limited power source that meets the requirements of 760.41.

Non-power-limited electronic power supplies that do not supply energy directly through the use of transformers are covered by Exception No. 3 to 760.45, which permits overcurrent protection for the non-power-limited circuit conductors to be installed on the input side of the electronic power source rather than on the output side for 2-wire circuits only.

### 760.46 NPLFA Circuit Wiring

Installation of non-power-limited fire alarm circuits shall be in accordance with 110.3(B), 300.7, 300.11, 300.15, 300.17, 300.19(B), and other appropriate articles of Chapter 3.

*Exception No. 1:* As provided in 760.48 through 760.53.

*Exception No. 2:* Where other articles of this Code require other methods.

Section 760.46 requires that the appropriate wiring methods in Chapter 3 be used for non-power-limited circuits. However, 760.46, Exception No. 1, permits special non-power-limited cable types to be used in place of Chapter 3 wiring methods.

Section 760.46 requires that devices be mounted in accordance with Chapter 3. Section 300.11(A) requires devices and equipment to be securely mounted. Section 300.15(B) is referenced to require non-power-limited circuit terminations to be made in a box or conduit body. However, 300.15(E) permits devices with integral terminal enclosures and mounting brackets to be used without a box. Devices must be mounted on a box or conduit body where the instructions or listing require the use of a box. Fire alarm system components such as manual fire alarm boxes are

frequently tested. Therefore, secure mounting of the back box is necessary to ensure that the manual fire alarm device will remain in place. (See Exhibit 760.5.)

**EXHIBIT 760.5** Typical manual fire alarm box. (Courtesy of the Protectowire Fire Systems)

#### 760.48 Conductors of Different Circuits in Same Cable, Enclosure, or Raceway

**(A) Class 1 with NPLFA Circuits.** Class 1 and non-power-limited fire alarm circuits shall be permitted to occupy the same cable, enclosure, or raceway without regard to whether the individual circuits are alternating current or direct current, provided all conductors are insulated for the maximum voltage of any conductor in the enclosure or raceway.

**(B) Fire Alarm with Power-Supply Circuits.** Power-supply and fire alarm circuit conductors shall be permitted in the same cable, enclosure, or raceway only where connected to the same equipment.

#### 760.49 NPLFA Circuit Conductors

**(A) Sizes and Use.** Only copper conductors shall be permitted to be used for fire alarm systems. Size 18 AWG and 16 AWG conductors shall be permitted to be used, provided they supply loads that do not exceed the ampacities given in Table 402.5 and are installed in a raceway, an approved enclosure, or a listed cable. Conductors larger than 16 AWG shall not supply loads greater than the ampacities given in 310.15, as applicable.

The minimum size of conductors permitted to be used on non-power-limited fire protective signaling circuits is 18 AWG. The load must not exceed the conductor ampacities specified in Table 402.5.

*NFPA 72, National Fire Alarm and Signaling Code*, requires fire alarm device and appliance voltages to be between 85 and 110 percent of nominal rated voltage. Calculations should be made to ensure that all devices or appliances will be operating within these limits at full circuit load. Where future circuit extensions are anticipated, larger conductors should be considered. Some manufacturers specify maximum circuit loop resistances. The equipment specifications should be consulted to ensure that maximum allowable loop resistances are not exceeded.

**(B) Insulation.** Insulation on conductors shall be rated for 600 volts. Conductors larger than 16 AWG shall comply with Article 310. Conductors 18 AWG and 16 AWG shall be Type KF-2, KFF-2, PAFF, PTFF, PF, PFF, PGF, PGFF, RFH-2, RFHH-2, RFHH-3, SF-2, SFF-2, TF, TFF, TFN, TFFN, ZF, or ZFF. Conductors with other types and thickness of insulation shall be permitted if listed for non-power-limited fire alarm circuit use.

Informational Note: For application provisions, see Table 402.3.

**(C) Conductor Materials.** Conductors shall be solid or stranded copper.

*Exception to (B) and (C): Wire Types PAF and PTF shall be permitted only for high-temperature applications between 90°C (194°F) and 250°C (482°F).*

#### 760.51 Number of Conductors in Cable Trays and Raceways, and Ampacity Adjustment Factors

**(A) NPLFA Circuits and Class 1 Circuits.** Where only non-power-limited fire alarm circuit and Class 1 circuit conductors are in a raceway, the number of conductors shall be determined in accordance with 300.17. The ampacity adjustment factors given in 310.15(B)(3)(a) shall apply if such conductors carry continuous load in excess of 10 percent of the ampacity of each conductor.

**(B) Power-Supply Conductors and Fire Alarm Circuit Conductors.** Where power-supply conductors and fire alarm circuit conductors are permitted in a raceway in accordance with 760.48, the number of conductors shall be determined in accordance with 300.17. The ampacity adjustment factors given in 310.15(B)(3)(a) shall apply as follows:

(1) To all conductors where the fire alarm circuit conductors carry continuous loads in excess of 10 percent of

the ampacity of each conductor and where the total number of conductors is more than three

- (2) To the power-supply conductors only, where the fire alarm circuit conductors do not carry continuous loads in excess of 10 percent of the ampacity of each conductor and where the number of power-supply conductors is more than three

**(C) Cable Trays.** Where fire alarm circuit conductors are installed in cable trays, they shall comply with 392.22 and 392.80(A).

### 760.53 Multiconductor NPLFA Cables

Multiconductor non-power-limited fire alarm cables that meet the requirements of 760.176 shall be permitted to be used on fire alarm circuits operating at 150 volts or less and shall be installed in accordance with 760.53(A) and (B).

**(A) NPLFA Wiring Method.** Multiconductor non-power-limited fire alarm circuit cables shall be installed in accordance with 760.53(A)(1), (A)(2), and (A)(3).

**(1) In Raceways, Exposed on Ceilings or Sidewalls, or Fished in Concealed Spaces.** Cable splices or terminations shall be made in listed fittings, boxes, enclosures, fire alarm devices, or utilization equipment. Where installed exposed, cables shall be adequately supported and installed in such a way that maximum protection against physical damage is afforded by building construction such as baseboards, door frames, ledges, and so forth. Where located within 2.1 m (7 ft) of the floor, cables shall be securely fastened in an approved manner at intervals of not more than 450 mm (18 in.).

**(2) Passing Through a Floor or Wall.** Cables shall be installed in metal raceway or rigid nonmetallic conduit where passing through a floor or wall to a height of 2.1 m (7 ft) above the floor, unless adequate protection can be afforded by building construction such as detailed in 760.53(A)(1), or unless an equivalent solid guard is provided.

**(3) In Hoistways.** Cables shall be installed in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit, or electrical metallic tubing where installed in hoistways.

*Exception:* As provided for in 620.21 for elevators and similar equipment.

**(B) Applications of Listed NPLFA Cables.** The use of non-power-limited fire alarm circuit cables shall comply with 760.53(B)(1) through (B)(4).

**(1) Ducts.** Multiconductor non-power-limited fire alarm circuit cables, Types NPLFP, NPLFR, and NPLF, shall not be installed exposed in ducts.

Informational Note: See 300.22(B).

Wiring methods for non-power-limited circuits in ducts and plenums must be in accordance with the Chapter 3 wiring methods covered by 300.22(B). Cables marked NPLFP may not be installed in ducts or plenums. They are permitted in other spaces for environmental air. See 760.53(B)(2). The higher possible voltages and currents of non-power-limited fire alarm circuits preclude the use of the listed cables inside plenums.

**(2) Other Spaces Used for Environmental Air.** Cables installed in other spaces used for environmental air shall be Type NPLFP.

*Exception No. 1: Types NPLFR and NPLF cables installed in compliance with 300.22(C).*

*Exception No. 2: Other wiring methods in accordance with 300.22(C) and conductors in compliance with 760.49(C).*

Other spaces used for environmental air are covered by 300.22(C) and the related informational note. Spaces over suspended ceilings used as an environmental air-handling return are considered by the Code as "other spaces used for environmental air." Non-power-limited cables used in other spaces used for environmental air must be marked NPLFP. [See 760.176(C).]

*Exception No. 3: Type NPLFP-CI cable shall be permitted to be installed to provide a 2-hour circuit integrity rated cable.*

**(3) Riser.** Cables installed in vertical runs and penetrating more than one floor or cables installed in vertical runs in a shaft shall be Type NPLFR. Floor penetrations requiring Type NPLFR shall contain only cables suitable for riser or plenum use.

*Exception No. 1: Type NPLF or other cables that are specified in Chapter 3 and are in compliance with 760.49(C) and encased in metal raceway.*

*Exception No. 2: Type NPLF cables located in a fireproof shaft having firestops at each floor.*

Informational Note: See 300.21 for firestop requirements for floor penetrations.

*Exception No. 3: Type NPLF-CI cable shall be permitted to be installed to provide a 2-hour circuit integrity rated cable.*

**(4) Other Wiring Within Buildings.** Cables installed in building locations other than the locations covered in 760.53(B)(1), (B)(2), and (B)(3) shall be Type NPLF.

*Exception No. 1: Chapter 3 wiring methods with conductors in compliance with 760.49(C).*

*Exception No. 2: Type NPLFP or Type NPLFR cables shall be permitted.*

*Exception No. 3: Type NPLFR-CI cable shall be permitted to be installed to provide a 2-hour circuit integrity rated cable.*

### III. Power-Limited Fire Alarm (PLFA) Circuits

#### 760.121 Power Sources for PLFA Circuits

**(A) Power Source.** The power source for a power-limited fire alarm circuit shall be as specified in 760.121(A)(1), (A)(2), or (A)(3).

Informational Note No. 1: Tables 12(A) and 12(B) in Chapter 9 provide the listing requirements for power-limited fire alarm circuit sources.

Informational Note No. 2: See 210.8(A)(5), Exception, for receptacles in dwelling-unit unfinished basements that supply power for fire alarm systems.

- (1) A listed PLFA or Class 3 transformer.
- (2) A listed PLFA or Class 3 power supply.
- (3) Listed equipment marked to identify the PLFA power source.

Informational Note: Examples of listed equipment are a fire alarm control panel with integral power source; a circuit card listed for use as a PLFA source, where used as part of a listed assembly; a current-limiting impedance, listed for the purpose or part of a listed product, used in conjunction with a non-power-limited transformer or a stored energy source, for example, storage battery, to limit the output current.

**(B) Branch Circuit.** The branch circuit supplying the fire alarm equipment(s) shall supply no other loads. The location of the branch-circuit overcurrent protective device shall be permanently identified at the fire alarm control unit. The circuit disconnecting means shall have red identification, shall be accessible only to qualified personnel, and shall be identified as "FIRE ALARM CIRCUIT." The red identification shall not damage the overcurrent protective devices or obscure the manufacturer's markings. This branch circuit shall not be supplied through ground-fault circuit interrupters or arc-fault circuit interrupters.

For more information on power source and branch-circuit requirements for fire alarm systems, see the commentary following 760.41(A) and (B). The requirements covering branch circuits for non-power-limited circuits and for power-limited circuits are the same.

#### 760.124 Circuit Marking

The equipment supplying PLFA circuits shall be durably marked where plainly visible to indicate each circuit that is a power-limited fire alarm circuit.

Informational Note: See 760.130(A), Exception No. 3, where a power-limited circuit is to be reclassified as a non-power-limited circuit.

#### 760.127 Wiring Methods on Supply Side of the PLFA Power Source

Conductors and equipment on the supply side of the power source shall be installed in accordance with the appropriate requirements of Part II and Chapters 1 through 4. Transformers or other devices supplied from power-supply conductors shall be protected by an overcurrent device rated not over 20 amperes.

*Exception: The input leads of a transformer or other power source supplying power-limited fire alarm circuits shall be permitted to be smaller than 14 AWG, but not smaller than 18 AWG, if they are not over 300 mm (12 in.) long and if they have insulation that complies with 760.49(B).*

#### 760.130 Wiring Methods and Materials on Load Side of the PLFA Power Source

Fire alarm circuits on the load side of the power source shall be permitted to be installed using wiring methods and materials in accordance with 760.130(A), (B), or a combination of (A) and (B).

Section 760.130 permits individual power-limited circuits to be installed using Chapter 3 wiring methods, non-power-limited fire alarm circuit wiring methods, power-limited circuit wiring methods, or a combination. If it is desirable to run power-limited circuits in the same cable or raceway with non-power-limited circuits, the power-limited circuits may be reclassified as permitted by 760.130(A), Exception No. 3. Also note the information contained in the informational note that follows 760.130(A), Exception No. 3, regarding circuit classification.

**(A) NPLFA Wiring Methods and Materials.** Installation shall be in accordance with 760.46, and conductors shall be solid or stranded copper.

*Exception No. 1: The ampacity adjustment factors given in 310.15(B)(3)(a) shall not apply.*

*Exception No. 2: Conductors and multiconductor cables described in and installed in accordance with 760.49 and 760.53 shall be permitted.*

*Exception No. 3: Power-limited circuits shall be permitted to be reclassified and installed as non-power-limited circuits if the power-limited fire alarm circuit markings required by 760.124 are eliminated and the entire circuit is installed using the wiring methods and materials in accordance with Part II, Non-Power-Limited Fire Alarm Circuits.*

Informational Note: Power-limited circuits reclassified and installed as non-power-limited circuits are no longer power-limited circuits, regardless of the continued connection to a power-limited source.

Section 760.130(A) permits any of the wiring methods in Chapter 3 to be used for power-limited circuits. In addition, 760.130(A), Exception No. 3, allows power-limited circuits to be reclassified and installed in accordance with the requirements for non-power-limited circuits. Where installed as non-power-limited circuits, the power-limited marking must be removed from equipment, overcurrent protection must be provided in accordance with 760.43, and reclassified circuits must maintain separation from power-limited circuits, in accordance with 760.48 and 760.133.

**(B) PLFA Wiring Methods and Materials.** Power-limited fire alarm conductors and cables described in 760.179 shall be installed as detailed in 760.130(B)(1), (B)(2), or (B)(3) of this section and 300.7. Devices shall be installed in accordance with 110.3(B), 300.11(A), and 300.15.

Section 760.130(B) requires mechanical protection at splices and termination points. Because failure of a circuit often occurs at splices or termination points, this requirement offers more protection and strain relief for these cable connections.

**(1) In Raceways, Exposed on Ceilings or Sidewalls, or Fished in Concealed Spaces.** Cable splices or terminations shall be made in listed fittings, boxes, enclosures, fire alarm devices, or utilization equipment. Where installed exposed, cables shall be adequately supported and installed in such a way that maximum protection against physical damage is afforded by building construction such as baseboards, door frames, ledges, and so forth. Where located within 2.1 m (7 ft) of the floor, cables shall be securely fastened in an approved manner at intervals of not more than 450 mm (18 in.).

**(2) Passing Through a Floor or Wall.** Cables shall be installed in metal raceways or rigid nonmetallic conduit where passing through a floor or wall to a height of 2.1 m (7 ft) above the floor, unless adequate protection can be afforded by building construction such as detailed in 760.130(B)(1), or unless an equivalent solid guard is provided.

**(3) In Hoistways.** Cables shall be installed in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, or electrical metallic tubing where installed in hoistways.

*Exception: As provided for in 620.21 for elevators and similar equipment.*

### 760.133 Installation of Conductors and Equipment in Cables, Compartments, Cable Trays, Enclosures, Manholes, Outlet Boxes, Device Boxes, and Raceways for Power-Limited Circuits

Conductors and equipment for power-limited fire alarm circuits shall be installed in accordance with 760.136 through 760.143.

### 760.136 Separation from Electric Light, Power, Class 1, NPLFA, and Medium-Power Network-Powered Broadband Communications Circuit Conductors

**(A) General.** Power-limited fire alarm circuit cables and conductors shall not be placed in any cable, cable tray, compartment, enclosure, manhole, outlet box, device box, raceway, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm circuits, and medium-power network-powered broadband communications circuits unless permitted by 760.136(B) through (G).

Jackets of listed power-limited fire alarm cables do not have sufficient construction specifications to permit them to be installed with electric light, power, Class 1, non-power-limited fire alarm circuits, and medium-power network-powered broadband communications cables. Failure of the cable insulation due to a fault could lead to hazardous voltages being imposed on the power-limited fire alarm circuit conductors.

**(B) Separated by Barriers.** Power-limited fire alarm circuit cables shall be permitted to be installed together with Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits where they are separated by a barrier.

**(C) Raceways Within Enclosures.** In enclosures, power-limited fire alarm circuits shall be permitted to be installed

in a raceway within the enclosure to separate them from Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuits.

**(D) Associated Systems Within Enclosures.** Power-limited fire alarm conductors in compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with electric light, power, Class 1, non–power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to power-limited fire alarm circuits, and comply with either of the following conditions:

- (1) The electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuit conductors are routed to maintain a minimum of 6 mm (0.25 in.) separation from the conductors and cables of power-limited fire alarm circuits.
- (2) The circuit conductors operate at 150 volts or less to ground and also comply with one of the following:
  - a. The fire alarm power-limited circuits are installed using Type FPL, FPLR, FPLP, or permitted substitute cables, provided these power-limited cable conductors extending beyond the jacket are separated by a minimum of 6 mm (0.25 in.) or by a nonconductive sleeve or nonconductive barrier from all other conductors.
  - b. The power-limited fire alarm circuit conductors are installed as non–power-limited circuits in accordance with 760.46.

**(E) Enclosures with Single Opening.** Power-limited fire alarm circuit conductors entering compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to power-limited fire alarm circuits or to other circuits controlled by the fire alarm system to which the other conductors in the enclosure are connected. Where power-limited fire alarm circuit conductors must enter an enclosure that is provided with a single opening, they shall be permitted to enter through a single fitting (such as a tee), provided the conductors are separated from the conductors of the other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing.

**(F) In Hoistways.** In hoistways, power-limited fire alarm circuit conductors shall be installed in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit, or electrical metallic

tubing. For elevators or similar equipment, these conductors shall be permitted to be installed as provided in 620.21.

**(G) Other Applications.** For other applications, power-limited fire alarm circuit conductors shall be separated by at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, non–power-limited fire alarm, or medium-power network-powered broadband communications circuits unless one of the following conditions is met:

- (1) Either (a) all of the electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuit conductors or (b) all of the power-limited fire alarm circuit conductors are in a raceway or in metal-sheathed, metal-clad, nonmetallic-sheathed, or Type UF cables.
- (2) All of the electric light, power, Class 1, non–power-limited fire alarm, and medium-power network-powered broadband communications circuit conductors are permanently separated from all of the power-limited fire alarm circuit conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the conductors.

### **760.139 Installation of Conductors of Different PLFA Circuits, Class 2, Class 3, and Communications Circuits in the Same Cable, Enclosure, Cable Tray, or Raceway**

**(A) Two or More PLFA Circuits.** Cable and conductors of two or more power-limited fire alarm circuits, communications circuits, or Class 3 circuits shall be permitted within the same cable, enclosure, cable tray, or raceway.

**(B) Class 2 Circuits with PLFA Circuits.** Conductors of one or more Class 2 circuits shall be permitted within the same cable, enclosure, cable tray, or raceway with conductors of power-limited fire alarm circuits, provided that the insulation of the Class 2 circuit conductors in the cable, enclosure, or raceway is at least that required by the power-limited fire alarm circuits.

**(C) Low-Power Network-Powered Broadband Communications Cables and PLFA Cables.** Low-power network-powered broadband communications circuits shall be permitted in the same enclosure, cable tray, or raceway with PLFA cables.

**(D) Audio System Circuits and PLFA Circuits.** Audio system circuits described in 640.9(C) and installed using Class 2 or Class 3 wiring methods in compliance with 725.133 and 725.154 shall not be permitted to be installed in the same cable, cable tray, or raceway with power-limited conductors or cables.

Section 760.139(D) prohibits audio circuits that are installed as Class 2 or Class 3 circuits from being installed in the same cable or raceway with power-limited fire alarm wiring. A fault between audio amplifier circuits and power-limited fire alarm circuits has the potential to impair the fire alarm system.

### 760.142 Conductor Size

Conductors of 26 AWG shall be permitted only where spliced with a connector listed as suitable for 26 AWG to 24 AWG or larger conductors that are terminated on equipment or where the 26 AWG conductors are terminated on equipment listed as suitable for 26 AWG conductors. Single conductors shall not be smaller than 18 AWG.

Due to a signaling method called *multiplexing* used with digitally addressable fire alarm systems, power-limited fire alarm cable is permitted to contain circuit conductors as small as 26 AWG, provided they are used as specified by 760.142 and as permitted by the listing or installation instructions of the specified fire alarm equipment.

### 760.143 Support of Conductors

Power-limited fire alarm circuit conductors shall not be strapped, taped, or attached by any means to the exterior of any conduit or other raceway as a means of support.

See the commentary following 760.24 for more information on the support of conductors.

### 760.145 Current-Carrying Continuous Line-Type Fire Detectors

**(A) Application.** Listed continuous line-type fire detectors, including insulated copper tubing of pneumatically operated detectors, employed for both detection and carrying signaling currents shall be permitted to be used in power-limited circuits.

**(B) Installation.** Continuous line-type fire detectors shall be installed in accordance with 760.124 through 760.130 and 760.133.

### 760.154 Applications of Listed PLFA Cables

PLFA cables shall comply with the requirements described in either 760.154(A), (B), or (C) or where cable substitutions are made as shown in 760.154(D).

**(A) Plenum.** Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type FPLP. Types

FPLP, FPLR, and FPL cables installed in compliance with 300.22 shall be permitted. Type FPLP-CI cable shall be permitted to be installed to provide a 2-hour circuit integrity rated cable.

**(B) Riser.** Cables installed in risers shall be as described in either (1), (2), or (3):

- (1) Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type FPLR. Floor penetrations requiring Type FPLR shall contain only cables suitable for riser or plenum use. Type FPLR-CI cable shall be permitted to be installed to provide a 2-hour circuit integrity rated cable.
- (2) Other cables shall be installed in metal raceways or located in a fireproof shaft having firestops at each floor.
- (3) Type FPL cable shall be permitted in one- and two-family dwellings.

Informational Note: See 300.21 for firestop requirements for floor penetrations.

**(C) Other Wiring Within Buildings.** Cables installed in building locations other than those covered in 760.154(A) or (B) shall be as described in either (C)(1), (C)(2), (C)(3), or (C)(4). Type FPL-CI cable shall be permitted to be installed as described in either (C)(1), (C)(2), (C)(3), or (C)(4) to provide a 2-hour circuit integrity rated cable.

Section 760.154(C) permits the use of circuit integrity cable for applications where survivability of fire alarm circuits is needed during a fire. Such circuits could be essential to communicating evacuation or relocation instructions to building occupants under fire or other emergency conditions.

**(1) General.** Type FPL shall be permitted.

**(2) In Raceways.** Cables shall be permitted to be installed in raceways.

**(3) Nonconcealed Spaces.** Cables specified in Chapter 3 and meeting the requirements of 760.179(A) and (B) shall be permitted to be installed in nonconcealed spaces where the exposed length of cable does not exceed 3 m (10 ft).

**(4) Portable Fire Alarm System.** A portable fire alarm system provided to protect a stage or set when not in use shall be permitted to use wiring methods in accordance with 530.12.

**(D) Fire Alarm Cable Substitutions.** The substitutions for fire alarm cables listed in Table 760.154(D) and illustrated

TABLE 760.154(D) Cable Substitutions

Cable Type	References	Permitted Substitutions
FPLP	760.154(A)	CMP
FPLR	760.154(B)	CMP, FPLP, CMR
FPL	760.154(C)	CMP, FPLP, CMR, FPLR, CMG, CM

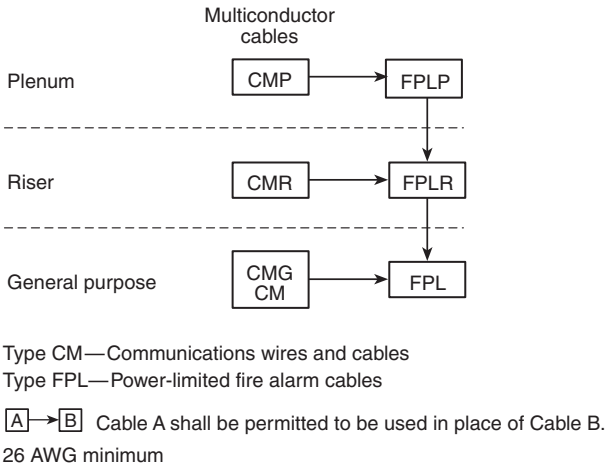

FIGURE 760.154(D) Cable Substitution Hierarchy.

in Figure 760.154(D) shall be permitted. Where substitute cables are installed, the wiring requirements of Article 760, Parts I and III, shall apply.

Informational Note: For information on communications cables (CMP, CMR, CMG, CM), see 800.179.

IV. Listing Requirements

760.176 Listing and Marking of NPLFA Cables

Non-power-limited fire alarm cables installed as wiring within buildings shall be listed in accordance with 760.176(A) and (B) and as being resistant to the spread of fire in accordance with 760.176(C) through (F), and shall be marked in accordance with 760.176(G). Cable used in a wet location shall be listed for use in wet locations or have a moisture-impervious metal sheath.

(A) **NPLFA Conductor Materials.** Conductors shall be 18 AWG or larger solid or stranded copper.

(B) **Insulated Conductors.** Insulated conductors shall be rated for 600 volts. Insulated conductors 14 AWG and larger shall be one of the types listed in Table 310.104(A) or one that is identified for this use. Insulated conductors 18 AWG and 16 AWG shall be in accordance with 760.49.

(C) **Type NPLFP.** Type NPLFP non-power-limited fire alarm cable for use in other space used for environmental air shall be listed as being suitable for use in other space used for environmental air as described in 300.22(C) and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

See the commentary following the informational note to 725.179(A) for more information on this test and the commentary following 760.53(B)(2), Exception No. 2, which discusses other spaces used for environmental air.

(D) **Type NPLFR.** Type NPLFR non-power-limited fire alarm riser cable shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass ANSI/UL 1666-2002, *Test for Flame Propagation Height of Electrical and Optical-Fiber Cables Installed Vertically in Shafts*.

See the commentary following the informational note to 725.179(B) for more information on this test.

(E) **Type NPLF.** Type NPLF non-power-limited fire alarm cable shall be listed as being suitable for general-purpose fire alarm use, with the exception of risers, ducts, plenums, and other space used for environmental air, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

For further information on the fire test method for Type NPLF cables used as other wiring within buildings, see the commentary following the informational note to 725.179(C).

**(F) Fire Alarm Circuit Integrity (CI) Cable or Electrical Circuit Protective System.** Cables used for survivability of critical circuits shall be listed as circuit integrity (CI) cable. Cables specified in 760.176(C), (D), and (E), and used for circuit integrity shall have the additional classification using the suffix “-CI.” Cables that are part of a listed electrical circuit protective system shall be considered to meet the requirements of survivability.

Informational Note No. 1: Fire alarm circuit integrity (CI) cable and electrical circuit protective systems may be used for fire alarm circuits to comply with the survivability requirements of *NFPA 72-2010, National Fire Alarm and Signaling Code*, 6.9.4.3 and 6.9.4.6, that the circuit maintain its electrical function during fire conditions for a defined period of time.

Informational Note No. 2: One method of defining circuit integrity (CI) cable is by establishing a minimum 2-hour fire resistance rating for the cable when tested in accordance with UL 2196-1995, *Standard for Tests of Fire Resistive Cables*.

Circuit integrity (CI) cable is intended to meet the performance requirements for survivability required by *NFPA 72, National Fire Alarm and Signaling Code*. This type of cable is designed to retain vital electrical performance during and immediately after fire exposure. Circuit integrity cable is considered a 2-hour-rated cable assembly and is an alternative to fire-rated mineral-insulated cable (Type MI).

**(G) NPLFA Cable Markings.** Multiconductor non-power-limited fire alarm cables shall be marked in accordance with Table 760.176(G). Non-power-limited fire alarm

TABLE 760.176(G) NPLFA Cable Markings

Cable Marking	Type	Reference
NPLFP	Non-power-limited fire alarm circuit cable for use in “other space used for environmental air”	760.176(C) and (G)
NPLFR	Non-power-limited fire alarm circuit riser cable	760.176(D) and (G)
NPLF	Non-power-limited fire alarm circuit cable	760.176(E) and (G)

Note: Cables identified in 760.176(C), (D), and (E) and meeting the requirements for circuit integrity shall have the additional classification using the suffix “CI” (for example, NPLFP-CI, NPLFR-CI, and NPLF-CI).

circuit cables shall be permitted to be marked with a maximum usage voltage rating of 150 volts. Cables that are listed for circuit integrity shall be identified with the suffix “CI” as defined in 760.176(F).

Informational Note: Cable types are listed in descending order of fire resistance rating.

760.179 Listing and Marking of PLFA Cables and Insulated Continuous Line-Type Fire Detectors

**PLFA** cables installed as wiring within buildings shall be listed as being resistant to the spread of fire and other criteria in accordance with 760.179(A) through (H) and shall be marked in accordance with 760.179(I). Insulated continuous line-type fire detectors shall be listed in accordance with 760.179(J). Cable used in a wet location shall be listed for use in wet locations or have a moisture-impervious metal sheath.

**(A) Conductor Materials.** Conductors shall be solid or stranded copper.

Some line-type fire detectors may not be made exclusively of copper but are listed for the application nevertheless.

**(B) Conductor Size.** The size of conductors in a multiconductor cable shall not be smaller than 26 AWG. Single conductors shall not be smaller than 18 AWG.

**(C) Ratings.** The cable shall have a voltage rating of not less than 300 volts.

**(D) Type FPLP.** Type FPLP power-limited fire alarm plenum cable shall be listed as being suitable for use in ducts, plenums, and other space used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

For further information on the fire test method for Type FPLP cables, see the commentary following the informational note to 725.179(A).

**(E) Type FPLR.** Type FPLR power-limited fire alarm riser cable shall be listed as being suitable for use in a vertical run

in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2002, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

For further information on the fire test method for Type FPLR cables, see the commentary following the informational note to 725.179(B).

**(F) Type FPL.** Type FPL power-limited fire alarm cable shall be listed as being suitable for general-purpose fire alarm use, with the exception of risers, ducts, plenums, and other spaces used for environmental air, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

For further information on the fire test method for FPL cables, see the commentary following the informational note to 725.179(C).

**(G) Fire Alarm Circuit Integrity (CI) Cable or Electrical Circuit Protective System.** Cables used for survivability of critical circuits shall be listed as circuit integrity (CI) cable. Cables specified in 760.179(D), (E), (F), and (H) and used for circuit integrity shall have the additional classification using the suffix “-CI.” Cables that are part of a listed electrical circuit protective system shall be considered to meet the requirements of survivability.

Informational Note No. 1: Fire alarm circuit integrity (CI) cable and electrical circuit protective systems may be used for fire alarm circuits to comply with the survivability requirements of NFPA 72-2010, *National Fire Alarm and Signaling Code*, 6.9.4.3 and 6.9.4.6, that the circuit maintain its electrical function during fire conditions for a defined period of time.

Informational Note No. 2: One method of defining circuit integrity (CI) cable is by establishing a minimum 2-hour fire resistance rating for the cable when tested in accordance with UL 2196-1995, *Standard for Tests of Fire Resistive Cables*.

In coordination with certain requirements in NFPA 72, *National Fire Alarm and Signaling Code*, 760.179(G) requires listed circuit integrity (CI) cable for critical circuits of the fire alarm system, which must operate under severe conditions such as attack by fire. Informational Note No. 2 to 760.179(G) references cables tested in accordance with UL 2196, *Standard for Tests of Fire Resistive Cables*, to provide the 2-hour fire-rated circuit integrity cable recognized by NFPA 72. The construction of typical CI cable is illustrated in Exhibit 760.6.

**EXHIBIT 760.6** Circuit integrity cable. (Courtesy of RSCC Wire & Cable, LLC)

**(H) Coaxial Cables.** Coaxial cables shall be permitted to use 30 percent conductivity copper-covered steel center conductor wire and shall be listed as Type FPLP, FPLR, or FPL cable.

**(I) Cable Marking.** The cable shall be marked in accordance with Table 760.179(I). The voltage rating shall not be marked on the cable. Cables that are listed for circuit integrity shall be identified with the suffix CI as defined in 760.179(G).

Informational Note: Voltage ratings on cables may be misinterpreted to suggest that the cables may be suitable for Class 1, electric light, and power applications.

*Exception: Voltage markings shall be permitted where the cable has multiple listings and voltage marking is required for one or more of the listings.*

**TABLE 760.179(I) Cable Markings**

Cable Marking	Type
FPLP	Power-limited fire alarm plenum cable
FPLR	Power-limited fire alarm riser cable
FPL	Power-limited fire alarm cable

Note: Cables identified in 760.179(D), (E), and (F) as meeting the requirements for circuit integrity shall have the additional classification using the suffix “CI” (for example, FPLP-CI, FPLR-CI, and FPL-CI).

**(J) Insulated Continuous Line-Type Fire Detectors.** Insulated continuous line-type fire detectors shall be rated in accordance with 760.179(C), listed as being resistant to the spread of fire in accordance with 760.179(D) through (F), marked in accordance with 760.179(I), and the jacket compound shall have a high degree of abrasion resistance.

**Informational Note:** The general term *grounding conductor* as previously used in this article is replaced by either the term *bonding conductor* or the term *grounding electrode conductor* (GEC), where applicable, to more accurately reflect the application and function of the conductor.

This informational note explains the revision of the term *grounding conductor* to *bonding conductor* and *grounding electrode conductor* throughout Article 770.

This informational note and Figures 800(a) and 800(b) explain how the new, more precise terms (*bonding conductor* and *grounding electrode conductor*) are implemented in the requirements that formerly used the term *grounding conductor*. These terms are new to Article 770, but have had long-standing use in other *Code* articles. See Article 100 for their definitions.

## I. General

### 770.1 Scope

The provisions of this article apply to the installation of optical fiber cables, raceways, and cable routing assemblies. This article does not cover the construction of optical fiber cables and raceways.

Article 770 covers the installation of optical fiber cables, raceways, and cable routing assemblies. It provides applications and listing requirements for these raceways. UL lists these raceways to UL 2024, *Standard for Safety of Optical Fiber and Communication Cable Raceway*. UL lists optical fiber/communications cable routing assemblies to UL 2024A, *Outline of Investigation for Optical Fiber and Communication Cable Routing Assemblies*. Routing assemblies are U-shaped wiring troughs that may or may not have covers. (If they always had covers, effectively they would be raceways.) The significant difference between optical fiber or communications cable routing assemblies and optical fiber raceways is that the routing assemblies are larger and open, and therefore may present a greater fire load.

Article 770 permits the orderly development and use of optical fiber technology in conjunction with electrical conductors for communications, signaling, and control circuits in lieu of metallic conductors. The most common optical fiber cable used in buildings is nonconductive.

Because they are not affected by electrical noise, optical fiber cables may be desirable in some circumstances to transmit data or other communications where electrical noise is a problem. Optical fiber cables may be nonconductive, or they may be composite, containing electrical conductors. See Exhibits 770.1 and 770.2.

### 770.2 Definitions

See Article 100. For purposes of this article, the following additional definitions apply.

**Abandoned Optical Fiber Cable.** Installed optical fiber cable that is not terminated at equipment other than a connector and not identified for future use with a tag.

Informational Note: See Article 100 for a definition of *Equipment*.

**EXHIBIT 770.1** An example of a nonconductive optical fiber cable.

**EXHIBIT 770.2** An example of a composite optical fiber cable. This cable also meets the requirements of Article 330 and is referred to as Type MC cable. (Courtesy of AFC Cable Systems, Inc.)

This definition is for use with 770.25, which requires removal of accessible abandoned optical fiber cable. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, it can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 800, 820, and 830.

**Cable Routing Assembly.** A single channel or connected multiple channels, as well as associated fittings, forming a structural system that is used to support, route and protect

high densities of wires and cables, typically communications wires and cables, optical fiber and data (Class 2 and Class 3) cables associated with information technology and communications equipment.

The definition uses the word “channel” in order to distinguish a cable routing assembly from a cable tray.

**Cable Sheath.** A covering over the optical fiber assembly that includes one or more jackets and may include one or more metallic members or strength members.

**Composite Optical Fiber Cable.** A cable containing optical fibers and current-carrying electrical conductors.

**Conductive Optical Fiber Cable.** A factory assembly of one or more optical fibers having an overall covering and containing non-current-carrying conductive member(s) such as metallic strength member(s), metallic vapor barrier(s), metallic armor or metallic sheath.

**Exposed (to Accidental Contact).** A conductive optical fiber cable in such a position that, in case of failure of supports or insulation, contact between the cable’s non-current-carrying conductive members and an electrical circuit may result.

Informational Note: See Article 100 for two other definitions of *Exposed*.

**Nonconductive Optical Fiber Cable.** A factory assembly of one or more optical fibers having an overall covering and containing no electrically conductive materials.

**Optical Fiber Cable.** A factory assembly of one or more optical fibers, having an overall covering, that transmits light for control, signaling, and communications.

**Optical Fiber Raceway.** An enclosed channel of nonmetallic materials designed for holding optical fiber cables in plenum, riser, and general-purpose applications.

**Point of Entrance.** The point within a building at which the cable emerges from an external wall, from a concrete floor slab, or from a rigid metal conduit (Type RMC) or an intermediate metal conduit (Type IMC) connected by a grounding conductor to an electrode in accordance with 770.100(B).

### 770.3 Other Articles

Installations of optical fiber cables and raceways shall comply with 770.3(A) and (B). Only those sections of Chapter 2 and Article 300 referenced in this article shall apply to optical fiber cables and raceways.

**(A) Hazardous (Classified) Locations.** Listed optical fiber cables shall be permitted to be installed in hazardous (classified) locations. The cables shall be sealed in accordance with the requirements of 501.15, 502.15, 505.16, or 506.16, as applicable.

Several sections in Article 770 reference hazardous (classified) locations. The suitability of equipment and wiring in hazardous (classified) locations is covered in Articles 500 through 516.

**(B) Composite Cables.** Composite optical fiber cables shall be classified as electrical cables in accordance with the type of electrical conductors. They shall be constructed, listed, and marked in accordance with the appropriate article for each type of electrical cable.

### 770.12 Innerduct for Optical Fiber Cables

Listed plenum optical fiber raceway, listed riser optical fiber raceway, or listed general-purpose optical fiber raceway selected in accordance with the provisions of 770.154 shall be permitted to be installed as innerduct in any type of listed raceway permitted in Chapter 3.

### 770.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of optical fiber cables that prevents removal of panels, including suspended ceiling panels.

See the commentary following 725.21 for information on safe access to electrical equipment behind panels.

### 770.24 Mechanical Execution of Work

Optical fiber cables shall be installed in a neat and workmanlike manner. Cables installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be secured by hardware including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with 300.4(D) and 300.11.

Informational Note No. 1: Accepted industry practices are described in ANSI/NECA/BICSI 568-2001, *Standard for Installing Commercial Building Telecommunications Cabling*, ANSI/NECA/FOA 301-2004, *Standard for Installing and Testing Fiber Optic Cables*, and other ANSI-approved installation standards.

Section 770.24 makes it clear that the *Code* requires optical fiber cables to be installed in a neat and workmanlike manner. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable should be carefully evaluated to ensure that activities and processes within the building do not cause damage to the cable.

The reference to 300.4(D) calls attention to the hazard to which cables are exposed where they are installed on framing members. Such cables are required to be installed in a manner that protects them from nail or screw penetration.

Informational Note No. 2: See NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, for discrete combustible components installed in accordance with 300.22(B) and (C).

Informational Note No. 2 addresses new requirements in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, that have an influence on installations covered in 770.24 of this *Code*. Fulfillment of the requirements of 770.24 affords a level of installation quality, cable support by suitable and appropriate hardware, and conformance with 300.4(D) and 300.11. However, it is not the intent of 770.24 to require that products in this section of the *Code* be listed, which would result in additional requirements not included in NFPA 90A. The implication of requiring listing in this section of the *Code* would impose the full scope of requirements in UL 1565, *Positioning Devices*, for cable ties and UL 2239, *Hardware for the Support of Conduit, Tubing, and Cable*, for other support hardware.

The NFPA 90A requirements are focused on smoke and heat generated from a fire in an air-handling plenum. NFPA 90A provides for discrete combustible components installed in air-handling spaces in accordance with 300.22(C) and (D) in this *Code*. When such is the case, NFPA 90A requires fixtures and other electrical equipment with combustible enclosures, including their assemblies and accessories, cable ties and other discrete products to be permitted in the ceiling cavity plenum where listed as having a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a peak heat release rate of 100 kW or less when tested in accordance with UL 2043, *Standard for Safety Fire Test for Heat and Visible Smoke Release for Discrete Products and Their Accessories Installed in Air-Handling Spaces*. Similar requirements in NFPA 90A apply for discrete combustible products installed in a raised floor plenum.

None of these requirements pertain to noncombustible products. There are many metallic products, including me-

tallic cable ties, used to support power, data, and communications conduits and cables and there has been no substantiation offered that these be required to be listed.

### 770.25 Abandoned Cables

The accessible portion of abandoned optical fiber cables shall be removed. Where cables are identified for future use with a tag, the tag shall be of sufficient durability to withstand the environment involved.

Section 770.25 requires the removal of accessible abandoned optical fiber cable. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, it can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 800, 820, and 830. See the definition of *abandoned optical fiber cable* in 770.2.

### 770.26 Spread of Fire or Products of Combustion

Installations of optical fiber cables and raceways in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations of optical fiber cables and raceways through fire-resistant-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

Informational Note: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made. Building codes also contain restrictions on membrane penetrations on opposite sides of a fire-resistance-rated wall assembly. An example is the 600-mm (24-in.) minimum horizontal separation that usually applies between boxes installed on opposite sides of the wall. Assistance in complying with 770.26 can be found in building codes, fire resistance directories, and product listings.

## II. Cables Outside and Entering Buildings

### 770.48 Unlisted Cables and Raceways Entering Buildings

**(A) Conductive and Nonconductive Cables.** Unlisted conductive and nonconductive outside plant optical fiber cables shall be permitted to be installed in building spaces, other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the

building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure.

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, typically are used as enclosures for splicing or terminating optical fiber cables.

Informational Note No. 2: See 770.2 for the definition of *Point of Entrance*.

**(B) Nonconductive Cables in Raceway.** Unlisted nonconductive outside plant optical fiber cables shall be permitted to enter the building from the outside and run in raceway systems installed in compliance with any of the following articles in Chapter 3: Article 342, Intermediate Metal Conduit: Type IMC; Article 344, Rigid Metal Conduit: Type RMC; Article 352, Rigid Polyvinyl Chloride Conduit: Type PVC; and Article 358, Electrical Metallic Tubing: Type EMT.

### III. Protection

#### 770.93 Grounding or Interruption of Non-Current-Carrying Metallic Members of Optical Fiber Cables

Optical fiber cables entering the building or terminating on the outside of the building shall comply with 770.93(A) or (B).

**(A) Entering Buildings.** In installations where an optical fiber cable is exposed to contact with electric light or power conductors and the cable enters the building, the non-current-carrying metallic members shall be either grounded as specified in 770.100, or interrupted by an insulating joint or equivalent device. The grounding or interruption shall be as close as practicable to the point of entrance.

**(B) Terminating On the Outside of Buildings.** In installations where an optical fiber cable is exposed to contact with electric light or power conductors and the cable is terminated on the outside of the building, the non-current-carrying metallic members shall be either grounded as specified in 770.100, or interrupted by an insulating joint or equivalent device. The grounding or interruption shall be as close as practicable to the point of termination of the cable.

### IV. Grounding Methods

#### 770.100 Entrance Cable Bonding and Grounding

Where required, the non-current-carrying metallic members of optical fiber cables entering buildings shall be bonded or grounded as specified in 770.100(A) through (D).

#### (A) Bonding Conductor or Grounding Electrode Conductor.

**(1) Insulation.** The bonding conductor or grounding electrode conductor shall be listed and shall be permitted to be insulated, covered, or bare.

**(2) Material.** The bonding conductor or grounding electrode conductor shall be copper or other corrosion-resistant conductive material, stranded or solid.

**(3) Size.** The bonding conductor or grounding electrode conductor shall not be smaller than 14 AWG. It shall have a current-carrying capacity not less than that of the grounded metallic member(s). The bonding conductor or grounding electrode conductor shall not be required to exceed 6 AWG.

**(4) Run in Straight Line.** The bonding conductor or grounding electrode conductor shall be run in as straight a line as practicable.

**(5) Physical Damage.** Where necessary, the bonding conductor and grounding electrode conductor shall be guarded from physical damage. Where these conductors are installed in a metal raceway, both ends of the raceway shall be bonded to the contained conductors or to the same terminal or electrode to which the conductor(s) is (are) connected.

**(B) Electrode.** The bonding conductor and grounding electrode conductor shall be connected in accordance with 770.100(B)(1), (B)(2), or (B)(3).

**(1) In Buildings or Structures with an Intersystem Bonding Termination.** If the building or structure served has an intersystem bonding termination as required by 250.94, the bonding conductor or grounding electrode conductor shall be connected to the intersystem bonding termination.

Informational Note: See Article 100 for the definition of *Intersystem Bonding Termination*.

**(2) In Buildings or Structures with Grounding Means.** If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on the following:

- (1) The building or structure grounding electrode system as covered in 250.50
- (2) The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52
- (3) The power service accessible means external to enclosures as covered in 250.94

- (4) The nonflexible metallic power service raceway
- (5) The service equipment enclosure
- (6) The grounding electrode conductor or the grounding electrode conductor metal enclosure of the power service, or
- (7) The grounding conductor or the grounding electrode of a building or structure disconnecting means that is grounded to an electrode as covered in 250.32

**(3) In Buildings or Structures Without Intersystem Bonding Termination or Grounding Means.** If the building or structure served has no intersystem bonding termination or grounding means, as described in 770.100(B)(2), the grounding electrode conductor shall be connected to either of the following:

- (1) To any one of the individual electrodes described in 250.52(A)(1), (A)(2), (A)(3), or (A)(4).
- (2) If the building or structure served has no grounding means, as described in 770.100(B)(2) or (B)(3)(1), to any one of the individual electrodes described in 250.52(A)(7) and (A)(8) or to a ground rod or pipe not less than 1.5 m (5 ft) in length and 12.7 mm (½ in.) in diameter, driven, where practicable, into permanently damp earth and separated from lightning conductors as covered in 800.53 and at least 1.8 m (6 ft) from electrodes of other systems. Steam or hot water pipes or air terminal conductors (lightning-rod conductors) shall not be employed as electrodes for non-current-carrying metallic members.

**(C) Electrode Connection.** Connections to grounding electrodes shall comply with 250.70.

**(D) Bonding of Electrodes.** A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the grounding electrode and power grounding electrode system at the building or structure served where separate electrodes are used.

*Exception: At mobile homes as covered in 770.106.*

Informational Note No. 1: See 250.60 for use of air terminals (lightning rods).

Informational Note No. 2: Bonding together of all separate electrodes limits potential differences between them and between their associated wiring systems.

Refer to the informational note following the Article 770 title for clarification of the use of the terms *grounding electrode conductor* and *bonding conductor*.

## 770.106 Grounding and Bonding of Entrance Cables at Mobile Homes

**(A) Grounding.** Grounding shall comply with 770.106(A)(1) and (A)(2).

- (1) Where there is no mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the non-current-carrying metallic members of optical fiber cables entering the mobile home shall be grounded in accordance with 770.100(B)(3).
- (2) Where there is no mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the non-current-carrying metallic members of optical fiber cables entering the mobile home shall be grounded in accordance with 770.100(B)(3).

**(B) Bonding.** The grounding electrode shall be bonded to the metal frame or available grounding terminal of the mobile home with a copper conductor not smaller than 12 AWG under either of the following conditions:

- (1) Where there is no mobile home service equipment or disconnecting means as in 770.106(A)
- (2) Where the mobile home is supplied by cord and plug

Refer to the informational note following the Article 770 title for clarification of the use of the terms *grounding electrode conductor* and *bonding conductor*.

## V. Installation Methods Within Buildings

### 770.110 Raceways for Optical Fiber Cables

**(A) Types of Raceways.** Optical fiber cables shall be permitted to be installed in any raceway that complies with either (A)(1) or (A)(2).

**(1) Raceways Recognized in Chapter 3.** Optical fiber cables shall be permitted to be installed in any raceway included in Chapter 3. The raceways shall be installed in accordance with the requirements of Chapter 3.

**(2) Other Permitted Raceways.** Optical fiber cables shall be permitted to be installed in listed plenum optical fiber raceway, listed plenum communications raceway, listed riser optical fiber raceway, listed riser communications raceway, listed general-purpose optical fiber raceway, or listed general-purpose communications raceway selected in accordance with the provisions of 770.113, and installed in

accordance with 362.24 through 362.56, where the requirements applicable to electrical nonmetallic tubing apply.

**(B) Raceway Fill for Optical Fiber Cables.** Raceway fill for optical fiber cables shall comply with either (B)(1) or (B)(2).

**(1) Without Electric Light or Power Conductors.** Where optical fiber cables are installed in raceway without electric light or power conductors, the raceway fill requirements of Chapters 3 and 9 shall not apply.

**(2) Nonconductive Optical Fiber Cables with Electric Light or Power Conductors.** Where nonconductive optical fiber cables are installed with electric light or power conductors in a raceway, the raceway fill requirements of Chapters 3 and 9 shall apply.

Conduit fill requirements apply where optical fiber cables are installed in a raceway with electrical conductors. Chapter 3 provides the raceway fill requirements that will direct the user of the *Code* to Chapter 9 for the cylindrical raceway fill tables.

### 770.113 Installation of Optical Fiber Cables and Raceways, and Cable Routing Assemblies

Installation of optical fiber cables and raceways, and cable routing assemblies shall comply with 770.113(A) through (J). Installation of raceways shall also comply with 770.12 and 770.110.

**(A) Listing.** Optical fiber cables and raceways, and cable routing assemblies installed in buildings shall be listed.

*Exception: Optical fiber cables that comply with 770.48 shall not be required to be listed.*

**(B) Fabricated Ducts Used for Environmental Air.** The following cables shall be permitted in ducts, as described in 300.22(B) if they are directly associated with the air distribution system:

- (1) Up to 1.22 m (4 ft) of Types OFNP and OFCP cables
- (2) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in raceways that are installed in compliance with 300.22(B)

Informational Note: For information on fire protection of wiring installed in fabricated ducts see 4.3.4.1 and 4.3.11.3.3 in NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(C) Other Spaces Used For Environmental Air (Plenums).** The following cables and raceways shall be permitted

in other spaces used for environmental air as described in 300.22(C):

- (1) Types OFNP and OFCP cables
- (2) Plenum optical fiber raceway
- (3) Types OFNP and OFCP cables installed in plenum optical fiber raceway or plenum communications raceway
- (4) Types OFNP and OFCP cables and plenum optical fiber raceways supported by open metallic cable trays or cable tray systems
- (5) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in raceways that are installed in compliance with 300.22(C)
- (6) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables and plenum optical fiber raceways, riser optical fiber raceways and general-purpose optical fiber raceways supported by solid bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air see 4.3.11.2, 4.3.11.4, and 4.3.11.5 of NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(D) Risers — Cables, Raceways and Cable Routing Assemblies in Vertical Runs.** The following cables, raceways and cable routing assemblies shall be permitted in vertical runs penetrating one or more floors and in vertical runs in a shaft:

- (1) Types OFNP, OFCP, OFNR, and OFCR cables
- (2) Plenum and riser optical fiber raceways
- (3) Riser cable routing assemblies
- (4) Types OFNP, OFCP, OFNR, and OFCR cables installed in:
  - a. Plenum optical fiber raceway
  - b. Plenum communications raceway
  - c. Riser optical fiber raceway
  - d. Riser communications raceway
  - e. Riser cable routing assembly

Informational Note: See 770.26 for firestop requirements for floor penetrations.

**(E) Risers — Cables and Raceways in Metal Raceways.** The following cables and raceways shall be permitted in metal raceways in a riser having firestops at each floor:

- (1) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables
- (2) Plenum, riser, and general-purpose optical fiber raceways
- (3) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in:

- a. Plenum optical fiber raceway
- b. Plenum communications raceway
- c. Riser optical fiber raceway
- d. Riser communications raceway
- e. General-purpose optical fiber raceway
- f. General-purpose communications raceway

Informational Note: See 770.26 for firestop requirements for floor penetrations.

**(F) Risers — Cables, Raceways, and Cable Routing Assemblies in Fireproof Shafts.** The following cables, raceways, and cable routing assemblies shall be permitted to be installed in fireproof riser shafts having firestops at each floor:

- (1) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables
- (2) Plenum, riser, and general-purpose optical fiber raceways
- (3) Riser and general-purpose cable routing assemblies
- (4) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in:
  - a. Plenum optical fiber raceway
  - b. Plenum communications raceway
  - c. Riser optical fiber raceway
  - d. Riser communications raceway
  - e. General-purpose optical fiber raceway
  - f. General-purpose communications raceway
  - g. Riser cable routing assembly
  - h. General-purpose cable routing assembly

Informational Note: See 770.26 for firestop requirements for floor penetrations.

**(G) Risers — One- and Two-Family Dwellings.** The following cables, raceways, and cable routing assemblies shall be permitted in one- and two-family dwellings:

- (1) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables
- (2) Plenum, riser, and general-purpose optical fiber raceways
- (3) Riser and general-purpose cable routing assemblies
- (4) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in:
  - a. Plenum optical fiber raceway
  - b. Plenum communications raceway
  - c. Riser optical fiber raceway
  - d. Riser communications raceway
  - e. General-purpose optical fiber raceway
  - f. General-purpose communications raceway
  - g. Riser cable routing assembly
  - h. General-purpose cable routing assembly

**(H) Cable Trays.** The following cables and raceways shall be permitted to be supported by cable trays:

- (1) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables
- (2) Plenum, riser, and general-purpose optical fiber raceways
- (3) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in:
  - a. Plenum optical fiber raceway
  - b. Plenum communications raceway
  - c. Riser optical fiber raceway
  - d. Riser communications raceway
  - e. General-purpose optical fiber raceway
  - f. General-purpose communications raceway

**(I) Distributing Frames and Cross-Connect Arrays.** The following cables, raceways, and cable routing assemblies shall be permitted to be installed in distributing frames and cross-connect arrays:

- (1) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables
- (2) Plenum, riser, and general-purpose optical fiber raceways
- (3) Riser or general-purpose cable routing assemblies
- (4) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in:
  - a. Plenum optical fiber raceway
  - b. Plenum communications raceway
  - c. Riser optical fiber raceway
  - d. Riser communications raceway
  - e. General-purpose optical fiber raceway
  - f. General-purpose communications raceway
  - g. Riser cable routing assembly
  - h. General-purpose cable routing assembly

**(J) Other Building Locations.** The following cables, raceways, and cable routing assemblies shall be permitted to be installed in building locations other than the locations covered in 770.113(B) through (I):

- (1) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables
- (2) Plenum, riser, and general-purpose optical fiber raceways
- (3) Riser and general-purpose cable routing assemblies
- (4) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in:
  - a. Plenum optical fiber raceway
  - b. Plenum communications raceway
  - c. Riser optical fiber raceway
  - d. Riser communications raceway
  - e. General-purpose optical fiber raceway
  - f. General-purpose communications raceway
  - g. Riser cable routing assembly
  - h. General-purpose cable routing assembly

- (5) Types OFNP, OFCP, OFNR, OFCR, OFNG, OFCG, OFN, and OFC cables installed in a raceway of a type recognized in Chapter 3

### 770.114 Grounding

Non-current-carrying conductive members of optical fiber cables shall be bonded to a grounded equipment rack or enclosure, or grounded in accordance with the grounding methods specified by 770.100(B)(2).

## 770.133 Installation of Optical Fibers and Electrical Conductors

### (A) With Conductors for Electric Light, Power, Class 1, Non-Power-Limited Fire Alarm, or Medium Power Network-Powered Broadband Communications Circuits.

When optical fibers are within the same composite cable for electric light, power, Class 1, non-power-limited fire alarm, or medium-power network-powered broadband communications circuits operating at 600 volts or less, they shall be permitted to be installed only where the functions of the optical fibers and the electrical conductors are associated.

Nonconductive optical fiber cables shall be permitted to occupy the same cable tray or raceway with conductors for electric light, power, Class 1, non-power-limited fire alarm, Type ITC, or medium-power network-powered broadband communications circuits, operating at 600 volts or less. Conductive optical fiber cables shall not be permitted to occupy the same cable tray or raceway with conductors for electric light, power, Class 1, non-power-limited fire alarm, Type ITC, or medium-power network-powered broadband communications circuits.

Optical fibers in composite optical fiber cables containing only current-carrying conductors for electric light, power, Class 1 circuits rated 600 volts or less shall be permitted to occupy the same cabinet, cable tray, outlet box, panel, raceway, or other termination enclosure with conductors for electric light, power, or Class 1 circuits operating at 600 volts or less.

Nonconductive optical fiber cables shall not be permitted to occupy the same cabinet, outlet box, panel, or similar enclosure housing the electrical terminations of an electric light, power, Class 1, non-power-limited fire alarm, or medium-power network-powered broadband communications circuit.

*Exception No. 1: Occupancy of the same cabinet, outlet box, panel, or similar enclosure shall be permitted where nonconductive optical fiber cable is functionally associated with the electric light, power, Class 1, non-power-limited fire alarm, or medium-power network-powered broadband communications circuit.*

*Exception No. 2: Occupancy of the same cabinet, outlet box, panel, or similar enclosure shall be permitted where*

*nonconductive optical fiber cables are installed in factory- or field-assembled control centers.*

*Exception No. 3: In industrial establishments only, where conditions of maintenance and supervision ensure that only qualified persons service the installation, nonconductive optical fiber cables shall be permitted with circuits exceeding 600 volts.*

*Exception No. 4: In industrial establishments only, where conditions of maintenance and supervision ensure that only qualified persons service the installation, optical fibers in composite optical fiber cables containing current-carrying conductors operating over 600 volts shall be permitted to be installed.*

*Exception No. 5: Where all of the conductors of electric light, power, Class 1, nonpower-limited fire alarm, and medium-power network-powered broadband communications circuits are separated from all of the optical fiber cables by a permanent barrier or listed divider.*

**(B) With Communications Cables.** Optical fibers shall be permitted in the same cable, and conductive and nonconductive optical fiber cables shall be permitted in the same cable tray, enclosure, raceway, or cable routing assembly, with conductors of any of the following:

- 
- (1) Communications circuits in compliance with Parts I and IV of Article 800
- (2) Community antenna television and radio distribution systems in compliance with Parts I and IV of Article 820
- (3) Low-power network-powered broadband communications circuits in compliance with Parts I and IV of Article 830

**(C) With Other Circuits.** Optical fibers shall be permitted in the same cable, and conductive and nonconductive optical fiber cables shall be permitted in the same cable tray, enclosure, or raceway, with conductors of any of the following:

- (1) Class 2 and Class 3 remote-control, signaling, and power-limited circuits in compliance with Parts I and III of Article 725
- (2) Power-limited fire alarm systems in compliance with Parts I and III of Article 760

**(D) Support of Cables.** Raceways shall be used for their intended purpose. Optical fiber cables shall not be strapped, taped, or attached by any means to the exterior of any conduit or raceway as a means of support.

*Exception: Overhead (aerial) spans of optical fiber cables shall be permitted to be attached to the exterior of a race-*

way-type mast intended for the attachment and support of such cables.

### 770.154 Applications of Listed Optical Fiber Cables and Raceways, and Cable Routing Assemblies

Permitted and nonpermitted applications of listed optical fiber cables and raceways, and cable routing assembly types

shall be as indicated in Table 770.154(a). The permitted applications shall be subject to the installation requirements of 770.110 and 770.113. The substitutions for optical fiber cables in Table 770.154(b) and illustrated in Figure 770.154 shall be permitted.

Table 770.154(a) summarizes the applications for the cable, raceway, and cable routing assemblies covered in Article

**TABLE 770.154(a) Applications of Listed Optical Fiber Cables and Raceways, and Cable Routing Assemblies in Buildings**

Applications		Cable, Raceway, and Cable Routing Assembly Type							
		OFNP, OFCP	OFNR, OFCR	OFNG, OFCG, OFN, OFC	Riser Cable Routing Assemblies	General-purpose Cable Routing Assemblies	Plenum Optical Fiber Raceway	Riser Optical Fiber Raceway	General-Purpose Optical Fiber Raceway
In fabricated ducts as described in 300.22(B)	In fabricated ducts	Y*	N	N	N	N	N	N	N
	In metal raceway that complies with 300.22(B)	Y*	Y*	Y*	N	N	Y*	Y*	Y*
In other spaces used for environmental air as described in 300.22(C)	In other spaces used for environmental air	Y*	N	N	N	N	Y*	N	N
	In metal raceway that complies with 300.22(C)	Y*	Y*	Y*	N	N	Y*	Y*	Y*
	In plenum optical fiber and communications raceways	Y*	N	N	N	N

TABLE 770.154(a) Continued

Applications		Cable, Raceway, and Cable Routing Assembly Type						
		OFNP, OFCP	OFNR, OFCR	OFNG, OFCG, OFN, OFC	Riser Cable Routing Assemblies	General-purpose Cable Routing Assemblies	Plenum Optical Fiber Raceway	Riser Optical Fiber Raceway
In riser optical fiber and communications raceway, and riser cable routing assemblies		Y*	Y*	Y*	N	N		
	In general-purpose optical fiber and communications raceway, and general-purpose cable routing assemblies	Y*	Y*	Y*	N	N		

Note: An “N” in the table indicates that the cable type is not permitted to be installed in the application. A “Y\*” indicates that the cable is permitted to be installed in the application, subject to the limitations described in 770.110 and 770.113.

Informational Note 1: Part V of Article 770 covers installation methods within buildings. This table covers the applications of listed optical fiber cables and raceways, and cable routing assemblies in buildings. The definition of point of entrance is in 770.2. Optical fiber entrance cables that have not emerged from the rigid metal conduit or intermediate metal conduit are not considered to be in the building.

Informational Note No. 2: For information on the restrictions to the installation of optical fiber cables in fabricated ducts see 770.113(B).

TABLE 770.154(b) Cable Substitutions

Cable Type	Permitted Substitutions
OFNP	None
OFCP	OFNP
OFNR	OFNP
OFCR	OFNP, OFCP, OFNR
OFNG, OFN	OFNP, OFNR
OFNG, OFN	OFNP, OFCP, OFNR, OFCR, OFNG, OFN

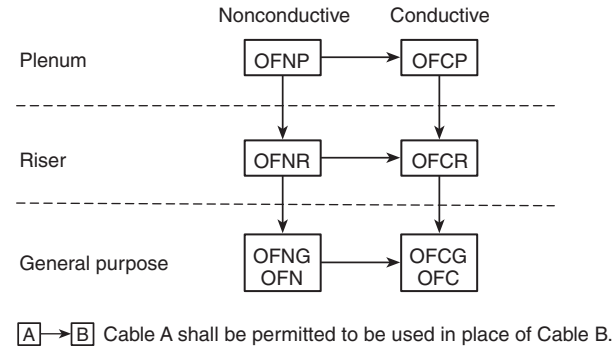

FIGURE 770.154 Cable Substitution Hierarchy.

(A) **Types OFNP and OFCP.** Types OFNP and OFCP nonconductive and conductive optical fiber plenum cables shall be listed as being suitable for use in ducts, plenums, and other space used for environmental air and shall also be listed as having adequate fire resistant and low smoke producing characteristics.

Informational Note: One method of defining a cable that is low smoke producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

For further information on the fire test method for optical fiber plenum cables, see the commentary following the informational note to 725.179(A).

770. Note that the permitted applications are a summary and are subject to the installation requirements of 770.110 and 770.113.

VI. Listing Requirements

770.179 Optical Fiber Cables

Optical fiber cables shall be listed in accordance with 770.179(A) through (E) and shall be marked in accordance with Table 770.179. Optical fiber cables shall have a temperature rating of not less than 60°C (140°F).

The last sentence of 770.179 requires that optical fiber cables have a temperature rating of not less than 140°F to correlate with requirements for communications wires and cables that are addressed in 800.179.

**(B) Types OFNR and OFCR.** Types OFNR and OFCR nonconductive and conductive optical fiber riser cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having the fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2002, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

For further information on the fire test method for optical fiber riser cables, see the commentary following the informational note to 725.179(B).

**(C) Types OFNG and OFCG.** Types OFNG and OFCG nonconductive and conductive general-purpose optical fiber cables shall be listed as being suitable for general-purpose use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

For further information on the fire test method for optical fiber cables used as other wiring within buildings, see the commentary following the informational note to 725.179(C).

**(D) Types OFN and OFC.** Types OFN and OFC nonconductive and conductive optical fiber cables shall be listed as being suitable for general-purpose use, with the exception of risers, plenums, and other spaces used for environmental air, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

Informational Note: Cable types are listed in descending order of fire resistance rating. Within each fire resistance

rating, nonconductive cable is listed first because it may substitute for the conductive cable.

**(E) Optical Fiber Circuit Integrity (CI) Cables.** Cables suitable for use in systems to ensure survivability of critical circuits and pathways during a specified time under fire conditions shall be additionally listed as circuit integrity (CI) cable. Cables identified in 770.179(A) through (D) that meet the requirements for circuit integrity shall have the additional classification using the suffix “CI.”

Informational Note: One method of defining circuit integrity (CI) cable is by establishing a minimum 2-hour fire resistance rating for the cable when tested in accordance with UL 2196-2001, *Standard for Tests of Fire Resistive Cable*.

Section 770.179(E) provides correlation with *NFPA 72, National Fire Alarm and Signaling Code*, Chapter 12, Circuits and Pathways. For further information on the fire test method for optical fiber circuit integrity cables, see the commentary following the informational note to 725.179(F).

**TABLE 770.179 Cable Markings**

Cable Marking	Type
OFNP	Nonconductive optical fiber plenum cable
OFCP	Conductive optical fiber plenum cable
OFNR	Nonconductive optical fiber riser cable
OFCR	Conductive optical fiber riser cable
OFNG	Nonconductive optical fiber general-purpose cable
OFCG	Conductive optical fiber general-purpose cable
OFN	Nonconductive optical fiber general-purpose cable
OFC	Conductive optical fiber general-purpose cable

## 770.182 Optical Fiber Raceways and Cable Routing Assemblies

Optical fiber raceways and cable routing assemblies shall be listed in accordance with 770.182(A) through (C).

Refer to the commentary in 770.2 following the definition of *cable routing assembly*.

**(A) Plenum Optical Fiber Raceway.** Plenum optical fiber raceways shall be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining that an optical fiber raceway is a low smoke producing raceway and a fire-resistant raceway is that the raceway exhibits a maximum

peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with the plenum test in UL 2024, *Standard for Optical Fiber Cable Raceway*.

**(B) Riser Optical Fiber Raceways and Cable Routing Assemblies.** Riser optical fiber raceways and riser cable routing assemblies shall be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

**Informational Note:** One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the raceways and cable routing assemblies pass the requirements of the test for flame propagation (riser) in UL 2024, *Standard for Optical Fiber Cable Raceway*, or UL 2024A, *Outline of Investigation for Cable Routing Assemblies*, as applicable.

**(C) General-Purpose Optical Fiber Cable Raceways and Cable Routing Assemblies.** General-purpose optical fiber cable raceways and cable routing assemblies shall be listed as being resistant to the spread of fire.

**Informational Note:** One method of defining resistance to the spread of fire is that the raceways and cable routing assemblies pass the requirements of the Vertical-Tray Flame Test (General Use) in UL 2024, *Standard for Optical Fiber Cable Raceway*, or UL 2024A, *Outline of Investigation for Cable Routing Assemblies*, as applicable.

The optical fiber raceways covered in 770.182 are listed raceways used in plenum, riser, or general-purpose applications. This listing includes raceways and fittings for installations of nonconductive optical fiber cables in accordance with Article 770. These raceways are not suitable for installation of current-carrying conductors, cords, or cables, nor are these raceways suitable for installations of hybrid cables that contain optical fiber members and current-carrying conductors. Typical optical fiber raceways are shown in Exhibit 770.3.

#### Plenum Raceway

A raceway marked “plenum” is suitable for use in ducts, plenums, or other spaces used for environmental air in accordance with 770.154 where used to enclose optical fiber cables marked OFNP. This plenum raceway exhibits a maximum peak optical density of 0.5, a maximum average optical density of 0.15, and a maximum flame-spread distance of 5 ft when tested in accordance with the plenum test in UL 2024, *Standard for Optical Fiber Cable Raceway*. This raceway is identified by a marking on the surface of the raceway or on a marker tape indicating “plenum.” A raceway marked “plenum” is also suitable for installation in risers where used

**EXHIBIT 770.3** Typical optical fiber raceways. (Courtesy of the International Association of Electrical Inspectors)

to enclose optical fiber cables marked OFNP or OFNR and for general-purpose use where used to enclose optical fiber cables marked OFNP, OFNR, OFNG, or OFN.

#### Riser Raceway

A raceway marked “riser” is suitable for installation in risers in accordance with 770.154 where used to enclose optical fiber cable marked OFNP or OFNR. This raceway has fire-resistant characteristics capable of preventing the carrying of fire from floor to floor. Riser raceway meets the flame propagation test requirements in UL 2024, *Standard for Optical Fiber Cable Raceway*. This raceway is identified by a marking on the surface of the raceway or on a marker tape indicating “riser.” A raceway marked “riser” is also suitable for general-purpose use when used to enclose optical fiber cable marked OFNP, OFNR, OFNG, or OFN.

#### General-Purpose Raceway

A raceway marked “general purpose” is suitable for installation in general-purpose areas in accordance with 770.154 where used to enclose optical fiber cable marked OFNP, OFNR, OFNG, or OFN. General-purpose raceway has fire-resistant characteristics that are capable of preventing the spread of fire as determined by the Vertical-Tray Flame Test in UL 2024, *Standard for Optical Fiber Raceway*.

Pliable raceway is raceway that can be bent by hand without the use of tools. The smallest radius of the curve of the inner edge of any bend to which the raceway may be bent without cracking either on the outer surface or internally is not less than 2½ times the outside diameter of the raceway.

Informational Note: The general term *grounding conductor* as previously used in this article is replaced by either the term *bonding conductor* or the term *grounding electrode conductor* (GEC), where applicable, to more accurately reflect the application and function of the conductor. See Informational Note Figure 800(a) and Figure 800(b).

This informational note explains the revision of the term *grounding conductor* to *bonding conductor* and *grounding electrode conductor* throughout Article 800.

This informational note and Figures 800(a) and 800(b) explain how the new, more precise terms (*bonding conductor* and *grounding electrode conductor*) are implemented in the requirements that formerly used the term *grounding conductor*. These terms are new to Article 800 but have had

**INFORMATIONAL NOTE FIGURE 800(a)** Example of the Use of the Term *Bonding Conductor* Used in a Communications Installation.

**INFORMATIONAL NOTE FIGURE 800(b)** Example of the Use of the Term *Grounding Electrode Conductor* Used in a Communications Installation.

long-standing use in other *Code* articles. See Article 100 for their definitions.

## I. General

### 800.1 Scope

This article covers communications circuits and equipment.

Informational Note No. 1: See 90.2(B)(4) for installations of communications circuits and equipment that are not covered.

Informational Note No. 2: For further information for remote-control, signaling, and power-limited circuits, see Article 725.

Informational Note No. 3: For further information for fire alarm systems, see Article 760.

Section 90.3, covering the structure of the *NEC*, specifies that Chapter 8 (comprised of Articles 800, 810, 820, 830, and 840) covers communications systems and is not subject to the requirements of Chapters 1 through 7, other than where a requirement from these chapters is specifically cited by a Chapter 8 requirement. As an example, 800.24 references 300.4(D) and 300.11, 800.44(A)(3) references 225.14(D), and 800.90(C) references 500.5 and 505.5.

Although information technology equipment systems are often used for or with communications systems, Article 800 does not cover wiring of this equipment. Instead, Article 645 provides requirements for wiring contained solely within an information technology equipment (computer) room. (See 645.4 for a description of the type of information technology equipment room to which Article 645 applies.) Article 725 provides requirements for wiring that extends beyond a computer room and also covers wiring of local area networks within buildings. Article 760 covers wiring requirements for fire alarm systems.

In some cases, telephone system wiring is also used for data transmission, which is covered by Article 800. Telephone company central offices are exempt from the requirements of Article 800 by 90.2(B)(4). The arrangement of the requirements in Article 800 is similar to those of Articles 725, 760, 770, 820, 830, and 840. *Communications equipment* (see Article 100 for definition), such as the private automatic branch exchange shown in Exhibit 800.1, and all of the premises wiring for a *communications circuit* (see 800.2 for definition), are subject to the requirements of Article 800.

## 800.2 Definitions

See Article 100. For the purposes of this article, the following additional definitions apply.

**Abandoned Communications Cable.** Installed communications cable that is not terminated at both ends at a connector or other equipment and not identified for future use with a tag.

The definition of *abandoned communications cable* applies to 800.25, which requires removal of accessible abandoned communications cable. Abandoned cable increases fire loading unnecessarily and, where installed in plenums, can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 770, 820, and 830.

Informational Note: See Article 100 for a definition of *Equipment*.

**Block.** A square or portion of a city, town, or village enclosed by streets and including the alleys so enclosed, but not any street.

**EXHIBIT 800.1** A private automatic branch exchange, one part of telecommunications equipment.

**Cable.** A factory assembly of two or more conductors having an overall covering.

**Cable Sheath.** A covering over the conductor assembly that may include one or more metallic members, strength members, or jackets.

**Communications Circuit.** The circuit that extends voice, audio, video, data, interactive services, telegraph (except radio), outside wiring for fire alarm and burglar alarm from the communications utility to the customer's communications equipment up to and including terminal equipment such as a telephone, fax machine, or answering machine.

**Communications Circuit Integrity (CI) Cable.** Cable used in communications systems to ensure continued operation of critical circuits during a specified time under fire conditions.

The definition of *communications circuit integrity (CI) cable* applies to a term used in 800.179(G). CI cables are used to maintain communications throughout the entire time of an

emergency. Such cable is intended to ensure the survivability of certain critical communications circuits during a building fire.

**Communications Raceway.** An enclosed channel of non-metallic materials designed for holding communications wires and cables in plenum, riser, and general-purpose applications.

**Exposed (to Accidental Contact).** A circuit that is in such a position that, in case of failure of supports or insulation, contact with another circuit may result.

Informational Note: See Article 100 for two other definitions of *Exposed*.

**Point of Entrance.** The point within a building at which the wire or cable emerges from an external wall, from a concrete floor slab, or from a rigid metal conduit (Type RMC) or an intermediate metal conduit (Type IMC) connected by a bonding conductor or grounding electrode in accordance with 800.100(B).

**Premises.** The land and buildings of a user located on the user side of the utility-user network point of demarcation.

**Wire.** A factory assembly of one or more insulated conductors without an overall covering.

See Article 100 for the definitions of *conductor*, *equipment*, and *raceway*.

### 800.3 Other Articles

**(A) Hazardous (Classified) Locations.** Communications circuits and equipment installed in a location that is classified in accordance with 500.5 and 505.5 shall comply with the applicable requirements of Chapter 5.

Section 800.3(A) alerts users that communications circuits installed in locations classified in accordance with 500.5 and 505.5 must conform to the requirements of Chapter 5 covering installations in hazardous (classified) locations.

**(B) Wiring in Ducts for Dust, Loose Stock, or Vapor Removal.** The requirements of 300.22(A) shall apply.

**(C) Equipment in Other Space Used for Environmental Air.** The requirements of 300.22(C) shall apply.

**(D) Network-Powered Broadband Communications Systems.** Article 830 shall apply to network-powered broadband communications systems.

**(E) Premises-Powered Broadband Communications Systems.** Article 840 shall apply to premises-powered broadband communications systems.

**(F) Optical Fiber Cable.** Where optical fiber cable is used, either in whole or in part, to provide a communications circuit within a building, Article 770 shall apply to the installation of the optical fiber portion of the communications circuit.

**(G) Cable Routing Assemblies.** The definition in 770.2, the applications in 770.154, and installation rules in 770.113 shall apply to Article 800.

### 800.18 Installation of Equipment

Equipment electrically connected to a communications network shall be listed in accordance with 800.170. Installation of equipment shall also comply with 110.3(B).

*Exception: This listing requirement shall not apply to test equipment that is intended for temporary connection to a telecommunications network by qualified persons during the course of installation, maintenance, or repair of telecommunications equipment or systems.*

UL 1863, *Communication Circuit Accessories*, and UL 60950, *Safety of Information Technology Equipment, Part 1: General Requirements*, are two safety standards that contain requirements for determining whether equipment connected to a telecommunications network is suitable for the intended purpose. Listed equipment that is connected to the telecommunications network and evaluated according to other U.S. safety standards is also subject to telecommunications requirements appropriate for the equipment. Examples of this equipment include information technology equipment, audio-video equipment, and signaling equipment connected to a central station. The appropriate requirements contained within the applicable safety standard are extracted from UL 1863, UL 60950, or both.

### 800.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of communications wires and cables that prevents removal of panels, including suspended ceiling panels.

An excess accumulation of wires and cables can limit access to equipment by preventing the removal of access panels. (See Exhibit 800.2.)

**EXHIBIT 800.2** Incorrect installation of conductors and cables (upper diagram), which can prevent access to equipment or cables. Correct method is shown in the lower diagram.

### 800.24 Mechanical Execution of Work

Communications circuits and equipment shall be installed in a neat and workmanlike manner. Cables installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be secured by hardware, including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11.

Section 800.24 provides definitive requirements for workmanship. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable must be carefully evaluated to ensure that activities and processes within the building do not damage the cable. Although this requirement does not contain specific supporting and securing intervals, it does reference 300.11 as a general rule on securing equipment and cables, and 300.4(D) for protection of cables installed parallel to framing methods. The equipment illustrated in Exhibit 800.3 is used by installers of telecommunications systems to organize cables and make connections in a neat and workmanlike manner.

Informational Note No. 1: Accepted industry practices are described in ANSI/NECA/BICSI 568-2006, *Standard for*

**EXHIBIT 800.3** Two examples of punch blocks used on a private automatic branch exchange.

*Installing Commercial Building Telecommunications Cabling*; ANSI/TIA/EIA-568-B.1-2004 — Part 1, General Requirements Commercial Building Telecommunications Cabling Standard; ANSI/TIA-569-B-2004, *Commercial Building Standard for Telecommunications Pathways and Spaces*; ANSI/TIA-570-B, *Residential Telecommunications Infrastructure*, and other ANSI-approved installation standards.

Informational Note No. 2: See NFPA 90A-2009, *Standard for Installation of Air-Conditioning and Ventilating Systems*, for discrete combustible components installed in accordance with 300.22(B) and (C).

### 800.25 Abandoned Cables

The accessible portion of abandoned communications cables shall be removed. Where cables are identified for future use with a tag, the tag shall be of sufficient durability to withstand the environment involved.

This section requires the removal of abandoned communications cable that is accessible. See Article 100 for the definition of *accessible*. This requirement covers the portions of cable installations that are not permanently closed in by the building structure or finish or are capable of being removed without damaging the building structure or finish. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 770, 820, 830, and 840. (See the definition of *abandoned communications cable* in 800.2.)

## 800.26 Spread of Fire or Products of Combustion

Installations of communications cables and communications raceways in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations of communications cables and communications raceways through fire-resistant walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

**Informational Note:** Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made. Building codes also contain restrictions on membrane penetrations on opposite sides of a fire resistance-rated wall assembly. An example is the 600 mm (24 in.) minimum horizontal separation that usually applies between boxes installed on opposite sides of the wall. Assistance in complying with 800.26 can be found in building codes, fire resistance directories, and product listings.

## II. Wires and Cables Outside and Entering Buildings

### 800.44 Overhead (Aerial) Communications Wires and Cables

Overhead (aerial) communications wires and cables entering buildings shall comply with 800.44(A) and (B).

**(A) On Poles and In-Span.** Where communications wires and cables and electric light or power conductors are supported by the same pole or are run parallel to each other in-span, the conditions described in 800.44(A)(1) through (A)(4) shall be met.

**(1) Relative Location.** Where practicable, the communications wires and cables shall be located below the electric light or power conductors.

**(2) Attachment to Cross-Arms.** Communications wires and cables shall not be attached to a cross-arm that carries electric light or power conductors.

**(3) Climbing Space.** The climbing space through communications wires and cables shall comply with the requirements of 225.14(D).

**(4) Clearance.** Supply service drops of 0–750 volts running above and parallel to communications service drops shall have a minimum separation of 300 mm (12 in.) at any point in the span, including the point of and at their attachment to the building, provided the nongrounded conductors are insulated and that a clearance of not less than 1.0 m (40 in.) is maintained between the two services at the pole.

**(B) Above Roofs.** Communications wires and cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

*Exception No. 1: Auxiliary buildings, such as garages and the like.*

*Exception No. 2: A reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (a) not more than 1.2 m (4 ft) of communications service-drop conductors pass above the roof overhang and (b) they are terminated at a through- or above-the-roof raceway or approved support.*

*Exception No. 3: Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.*

**Informational Note:** For additional information regarding overhead (aerial) wires and cables, see ANSI C2-2007, *National Electric Safety Code*, Part 2, Safety Rules for Overhead Lines.

### 800.47 Underground Communications Wires and Cables Entering Buildings

Underground communications wires and cables entering buildings shall comply with 800.47(A) and (B). The requirements of 310.10(C) shall not apply to communications wires and cables.

**(A) With Electric Light or Power Conductors.** Underground communications wires and cables in a raceway, handhole enclosure, or manhole containing electric light, power, Class 1, or non-power-limited fire alarm circuit conductors shall be in a section separated from such conductors by means of brick, concrete, or tile partitions or by means of a suitable barrier.

**(B) Underground Block Distribution.** Where the entire street circuit is run underground and the circuit within the

block is placed so as to be free from the likelihood of accidental contact with electric light or power circuits of over 300 volts to ground, the insulation requirements of 800.50(A) and (C) shall not apply, insulating supports shall not be required for the conductors, and bushings shall not be required where the conductors enter the building.

### 800.48 Unlisted Cables Entering Buildings

Unlisted outside plant communications cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated in an enclosure or on a listed primary protector.

Informational Note No. 1: Splice cases or terminal boxes, both metallic and plastic types, are typically used as enclosures for splicing or terminating telephone cables.

Informational Note No. 2: This section limits the length of unlisted outside plant cable to 15 m (50 ft), while 800.90(B) requires that the primary protector be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, the outside plant cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the entrance point.

Informational Note No. 3: See 800.2 for the definition of *Point of Entrance*.

### 800.50 Circuits Requiring Primary Protectors

Circuits that require primary protectors as provided in 800.90 shall comply with 800.50(A), (B), and (C).

**(A) Insulation, Wires, and Cables.** Communications wires and cables without a metallic shield, running from the last outdoor support to the primary protector, shall be listed in accordance with 800.173.

**(B) On Buildings.** Communications wires and cables in accordance with 800.50(A) shall be separated at least 100 mm (4 in.) from electric light or power conductors not in a raceway or cable or be permanently separated from conductors of the other systems by a continuous and firmly fixed nonconductor in addition to the insulation on the wires, such as porcelain tubes or flexible tubing. Communications wires and cables in accordance with 800.50(A) exposed to accidental contact with electric light and power conductors operating at over 300 volts to ground and attached to buildings shall be separated from woodwork by being supported on glass, porcelain, or other insulating material.

*Exception: Separation from woodwork shall not be required where fuses are omitted as provided for in 800.90(A)*

*(1), or where conductors are used to extend circuits to a building from a cable having a grounded metal sheath.*

**(C) Entering Buildings.** Where a primary protector is installed inside the building, the communications wires and cables shall enter the building either through a noncombustible, nonabsorbent insulating bushing or through a metal raceway. The insulating bushing shall not be required where the entering communications wires and cables (1) are in metal-sheathed cable, (2) pass through masonry, (3) meet the requirements of 800.50(A) and fuses are omitted as provided in 800.90(A)(1), or (4) meet the requirements of 800.50(A) and are used to extend circuits to a building from a cable having a grounded metallic sheath. Raceways or bushings shall slope upward from the outside or, where this cannot be done, drip loops shall be formed in the communications wires and cables immediately before they enter the building.

Raceways shall be equipped with an approved service head. More than one communications wire and cable shall be permitted to enter through a single raceway or bushing. Conduits or other metal raceways located ahead of the primary protector shall be grounded.

### 800.53 Lightning Conductors

Where practicable, a separation of at least 1.8 m (6 ft) shall be maintained between communications wires and cables on buildings and lightning conductors.

## III. Protection

### 800.90 Protective Devices

**(A) Application.** A listed primary protector shall be provided on each circuit run partly or entirely in aerial wire or aerial cable not confined within a block. Also, a listed primary protector shall be provided on each circuit, aerial or underground, located within the block containing the building served so as to be exposed to accidental contact with electric light or power conductors operating at over 300 volts to ground. In addition, where there exists a lightning exposure, each interbuilding circuit on a premises shall be protected by a listed primary protector at each end of the interbuilding circuit. Installation of primary protectors shall also comply with 110.3(B).

Informational Note No. 1: On a circuit not exposed to accidental contact with power conductors, providing a listed primary protector in accordance with this article helps protect against other hazards, such as lightning and above-normal voltages induced by fault currents on power circuits in proximity to the communications circuit.

Informational Note No. 2: Interbuilding circuits are considered to have a lightning exposure unless one or more of the following conditions exist:

- (1) Circuits in large metropolitan areas where buildings are close together and sufficiently high to intercept lightning.

- (2) Interbuilding cable runs of 42 m (140 ft) or less, directly buried or in underground conduit, where a continuous metallic cable shield or a continuous metallic conduit containing the cable is connected to each building grounding electrode system.
- (3) Areas having an average of five or fewer thunderstorm days per year and earth resistivity of less than 100 ohm-meters. Such areas are found along the Pacific coast.

Telephone utility companies ordinarily provide primary protectors if telephone lines are exposed to lightning. Installers of private networks that include interbuilding cable should also install primary protectors where cables are exposed to lightning. Generally, cable is not considered to be exposed to lightning unless one or more of the conditions in Informational Note No. 2 exist. A primary protector is required at each end of an interbuilding communications circuit where lightning exposure exists.

**(1) Fuseless Primary Protectors.** Fuseless-type primary protectors shall be permitted under any of the conditions given in (A)(1)(a) through (A)(1)(e).

(a) Where conductors enter a building through a cable with grounded metallic sheath member(s) and where the conductors in the cable safely fuse on all currents greater than the current-carrying capacity of the primary protector and of the primary protector bonding conductor or grounding electrode conductor

(b) Where insulated conductors in accordance with 800.50(A) are used to extend circuits to a building from a cable with an effectively grounded metallic sheath member(s) and where the conductors in the cable or cable stub, or the connections between the insulated conductors and the plant exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground, safely fuse on all currents greater than the current-carrying capacity of the primary protector, or the associated insulated conductors and of the primary protector bonding conductor or grounding electrode conductor

(c) Where insulated conductors in accordance with 800.50(A) or (B) are used to extend circuits to a building from other than a cable with metallic sheath member(s), where (1) the primary protector is listed as being suitable for this purpose for application with circuits extending from other than a cable with metallic sheath members, and (2) the connections of the insulated conductors to the plant exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground or the conductors of the plant exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground safely fuse on all currents greater than the current-carrying capacity of the primary protector, or associated in-

ulated conductors and of the primary protector bonding conductor or grounding electrode conductor

(d) Where insulated conductors in accordance with 800.50(A) are used to extend circuits aerially to a building from a buried or underground circuit that is unexposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground

(e) Where insulated conductors in accordance with 800.50(A) are used to extend circuits to a building from cable with an effectively grounded metallic sheath member(s), and where (1) the combination of the primary protector and insulated conductors is listed as being suitable for this purpose for application with circuits extending from a cable with an effectively grounded metallic sheath member(s), and (2) the insulated conductors safely fuse on all currents greater than the current-carrying capacity of the primary protector and of the primary protector bonding conductor or grounding electrode conductor

Informational Note: Section 9 of ANSI C2-2007, *National Electrical Safety Code*, provides an example of methods of protective grounding that can achieve effective grounding of communications cable sheaths for cables from which communications circuits are extended.

**(2) Fused Primary Protectors.** Where the requirements listed under 800.90(A)(1)(a) through (A)(1)(e) are not met, fused-type primary protectors shall be used. Fused-type primary protectors shall consist of an arrester connected between each line conductor and ground, a fuse in series with each line conductor, and an appropriate mounting arrangement. Primary protector terminals shall be marked to indicate line, instrument, and ground, as applicable.

**(B) Location.** The primary protector shall be located in, on, or immediately adjacent to the structure or building served and as close as practicable to the point of entrance.

Informational Note: See 800.2 for the definition of *Point of Entrance*.

For purposes of this section, primary protectors located at mobile home service equipment within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, or at a mobile home disconnecting means connected to an electrode by a grounding electrode conductor in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, shall be considered to meet the requirements of this section.

Informational Note: Selecting a primary protector location to achieve the shortest practicable primary protector grounding electrode conductor helps limit potential differences between communications circuits and other metallic systems.

Exhibit 800.4 shows an example of a primary protector unit typically installed in commercial buildings.

**EXHIBIT 800.4** A primary protector unit installed in a commercial building. This unit is the interface to the outside plant cable.

**(C) Hazardous (Classified) Locations.** The primary protector shall not be located in any hazardous (classified) locations, as defined in 500.5 and 505.5, or in the vicinity of easily ignitable material.

*Exception:* As permitted in 501.150, 502.150, and 503.150.

**(D) Secondary Protectors.** Where a secondary protector is installed in series with the indoor communications wire and cable between the primary protector and the equipment, it shall be listed for the purpose in accordance with 800.170(B).

**Informational Note:** Secondary protectors on circuits exposed to accidental contact with electric light or power conductors operating at greater than 300 volts to ground are not intended for use without primary protectors.

## 800.93 Grounding or Interruption of Metallic Sheath Members of Communications Cables

Communications cables entering the building or terminating on the outside of the building shall comply with 800.93(A) or (B).

**(A) Entering Buildings.** In installations where the communications cable enters a building, the metallic sheath members of the cable shall be either grounded as specified in 800.100 or interrupted by an insulating joint or equivalent device. The grounding or interruption shall be as close as practicable to the point of entrance.

**(B) Terminating on the Outside of Buildings.** In installations where the communications cable is terminated on the outside of the building, the metallic sheath members of the cable shall be either grounded as specified in 800.100 or interrupted by an insulating joint or equivalent device. The grounding or interruption shall be as close as practicable to the point of termination of the cable.

**Informational Note:** See 800.2 for a definition of *Point of Entrance*.

## IV. Grounding Methods

### 800.100 Cable and Primary Protector Bonding and Grounding

The primary protector and the metallic member(s) of the cable sheath shall be bonded or grounded as specified in 800.100(A) through (D).

#### (A) Bonding Conductor or Grounding Electrode Conductor.

**(1) Insulation.** The bonding conductor or grounding electrode conductor shall be listed and shall be permitted to be insulated, covered, or bare.

**(2) Material.** The bonding conductor or grounding electrode conductor shall be copper or other corrosion-resistant conductive material, stranded or solid.

**(3) Size.** The bonding conductor or grounding electrode conductor shall not be smaller than 14 AWG. It shall have a current-carrying capacity not less than the grounded metallic sheath member(s) and protected conductor(s) of the communications cable. The bonding conductor or grounding electrode conductor shall not be required to exceed 6 AWG.

**(4) Length.** The primary protector bonding conductor or grounding electrode conductor shall be as short as practicable. In one- and two-family dwellings, the primary protector

bonding conductor or grounding electrode conductor shall be as short as practicable, not to exceed 6.0 m (20 ft) in length.

Informational Note: Similar bonding conductor or grounding electrode conductor length limitations applied at apartment buildings and commercial buildings help to reduce voltages that may be developed between the building's power and communications systems during lightning events.

*Exception: In one- and two-family dwellings where it is not practicable to achieve an overall maximum primary protector bonding conductor or grounding electrode conductor length of 6.0 m (20 ft), a separate communications ground rod meeting the minimum dimensional criteria of 800.100(B)(3)(2) shall be driven, the primary protector shall be connected to the communications ground rod in accordance with 800.100(C), and the communications ground rod shall be connected to the power grounding electrode system in accordance with 800.100(D).*

For one- and two-family dwellings, 800.100(A)(4) restricts the length of the primary protector bonding conductor to 20 ft. This restricted conductor length reduces the impedance of the bonding conductor, resulting in a lower potential difference between the communications system conductors and equipment and the electrical conductors and equipment in the building. The low impedance bonding connection reduces the fire hazard and shock hazard to persons in the event that electric utility power lines come in contact with communications conductors. Section 800.100(D) requires bonding of communications and power grounding electrodes at the same building or structure.

The informational note to 800.100(A)(4) provides guidance for the treatment of the cable and primary protector grounding conductor length at apartment and commercial buildings that is consistent with the 20-ft rule for one- and two-family dwellings. However, a specific length is not specified in the *Code* because such a limitation may not be practical in some installations.

**(5) Run in Straight Line.** The bonding conductor or grounding electrode conductor shall be run in as straight a line as practicable.

**(6) Physical Protection.** Bonding conductors and grounding electrode conductors shall be protected where exposed to physical damage. Where the bonding conductor or grounding electrode conductor is installed in a metal raceway, both ends of the raceway shall be bonded to the contained conductor or to the same terminal or electrode to which the bonding conductor or grounding electrode conductor is connected.

**(B) Electrode.** The bonding conductor or grounding electrode conductor shall be connected in accordance with 800.100(B)(1), (B)(2), or (B)(3).

**(1) In Buildings or Structures with an Intersystem Bonding Termination.** If the building or structure served has an intersystem bonding termination as required by 250.94, the bonding conductor shall be connected to the intersystem bonding termination.

Informational Note: See Article 100 for the definition of *Intersystem Bonding Termination*.

**(2) In Buildings or Structures with Grounding Means.** If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on one of the following:

- (1) The building or structure grounding electrode system as covered in 250.50
- (2) The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52

For more information on the use of a metal water piping system as a grounding electrode, see the commentary following 250.52(A)(1).

- (3) The power service accessible means external to enclosures as covered in 250.94 *Exception*
- (4) The nonflexible metallic power service raceway
- (5) The service equipment enclosure
- (6) The grounding electrode conductor or the grounding electrode conductor metal enclosure of the power service, or
- (7) The grounding electrode conductor or the grounding electrode of a building or structure disconnecting means that is grounded to an electrode as covered in 250.32

A bonding device intended to provide a termination point for the grounding electrode conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on non-removable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is nonremovable.

For purposes of this section, the mobile home service equipment or the mobile home disconnecting means, as described in 800.90(B), shall be considered accessible.

**(3) In Buildings or Structures Without an Intersystem Bonding Termination or Grounding Means.** If the building or structure served has no intersystem bonding termination or grounding means, as described in 800.100(B)(2), the

grounding electrode conductor shall be connected to either of the following:

- (1) To any one of the individual electrodes described in 250.52(A)(1), (A)(2), (A)(3), or (A)(4)
- (2) If the building or structure served has no intersystem bonding termination or has no grounding means, as described in 800.100(B)(2) or (B)(3)(1), to any one of the individual grounding electrodes described in 250.52(A)(7) and (A)(8) or to a ground rod or pipe not less than 1.5 m (5 ft) in length and 12.7 mm (½ in.) in diameter, driven, where practicable, into permanently damp earth and separated from lightning conductors as covered in 800.53 and at least 1.8 m (6 ft) from electrodes of other systems. Steam or hot water pipes or air terminal conductors (lightning-rod conductors) shall not be employed as electrodes for protectors and grounded metallic members.

**(C) Electrode Connection.** Connections to grounding electrodes shall comply with 250.70.

**(D) Bonding of Electrodes.** A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the communications grounding electrode and power grounding electrode system at the building or structure served where separate electrodes are used.

*Exception: At mobile homes as covered in 800.106.*

Informational Note No. 1: See 250.60 for use of air terminals (lightning rods).

Informational Note No. 2: Bonding together of all separate electrodes limits potential differences between them and between their associated wiring systems.

## 800.106 Primary Protector Grounding and Bonding at Mobile Homes

**(A) Grounding.** Grounding shall comply with 800.106(A)(1) and (A)(2).

- (1) Where there is no mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the primary protector shall be connected to a grounding electrode conductor or grounding electrode in accordance with 800.100(B)(3).
- (2) Where there is no mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the primary protector shall be connected to a grounding electrode in accordance with 800.100(B)(3).

**(B) Bonding.** The primary protector grounding terminal or grounding electrode shall be connected to the metal frame or available grounding terminal of the mobile home with a copper conductor not smaller than 12 AWG under either of the

following conditions:

- (1) Where there is no mobile home service equipment or disconnecting means as in 800.106(A)
- (2) Where the mobile home is supplied by cord and plug

## V. Installation Methods Within Buildings

Data circuits between computers are classified as Class 2 circuits. In a typical office environment consisting of a group of computers connected to a local area network, data wiring is as prevalent as telephone wiring. One common way to minimize the amount of cabling is to run the telephone and data circuits in the same cable. Section 725.139(D) requires that a listed communications cable be used for this purpose.

### 800.110 Raceways for Communications Wires and Cables

**(A) Types of Raceways.** Communications wires and cables shall be permitted to be installed in any raceway that complies with either (A)(1) or (A)(2).

**(1) Raceways Recognized in Chapter 3.** Communications wires and cables shall be permitted to be installed in any raceway included in Chapter 3. The raceways shall be installed in accordance with the requirements of Chapter 3.

**(2) Other Permitted Raceways.** Communications wires and cables shall be permitted to be installed in listed plenum communications raceway, listed riser communications raceway, or listed general-purpose communications raceway selected in accordance with the provisions of 800.113, and installed in accordance with 362.24 through 362.56, where the requirements applicable to electrical nonmetallic tubing apply.

**(B) Raceway Fill for Communications Wires and Cables.** The raceway fill requirements of Chapters 3 and 9 shall not apply to communications wires and cables.

### 800.113 Installation of Communications Wires, Cables and Raceways

Installation of communications wires, cables, and raceways shall comply with 800.113(A) through (L). Installation of raceways shall also comply with 800.110.

**(A) Listing.** Communications wires, cables, and raceways installed in buildings shall be listed.

*Exception: Communications cables that comply with 800.48 shall not be required to be listed.*

**(B) Fabricated Ducts Used for Environmental Air.** The following wires and cables shall be permitted in ducts used for environmental air as described in 300.22(B) if they are directly associated with the air distribution system:

- (1) Up to 1.22 m (4 ft) of Type CMP cable
- (2) Types CMP, CMR, CMG, CM, and CMX cables and communications wires installed in raceways that are installed in compliance with 300.22(B)

Informational Note: For information on fire protection of wiring installed in fabricated ducts see 4.3.4.1 and 4.3.11.3.3 in NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(C) Other Spaces Used for Environmental Air (Plenums).** The following wires, cables, and raceways shall be permitted in other spaces used for environmental air as described in 300.22(C):

- (1) Type CMP cable
- (2) Plenum communications raceway
- (3) Type CMP cable installed in plenum communications raceway
- (4) Type CMP cables and plenum communications raceways supported by open metallic cable trays or cable tray systems
- (5) Types CMP, CMR, CMG, CM, and CMX cables and communications wires installed in raceways that are installed in compliance with 300.22(C)
- (6) Types CMP, CMR, CMG, CM, and CMX cables and plenum communications raceways, riser communications raceways and general-purpose communications raceways supported by solid bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air see 4.3.11.2, 4.3.11.4, and 4.3.11.5 of NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(D) Risers — Cables and Raceways in Vertical Runs.** The following cables and raceways shall be permitted in vertical runs penetrating one or more floors and in vertical runs in a shaft:

- (1) Types CMP and CMR cables
- (2) Plenum and riser communications raceways
- (3) Types CMP and CMR cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. Riser cable routing assembly

Informational Note: See 800.26 for firestop requirements for floor penetrations.

**(E) Risers — Cables and Raceways in Metal Raceways.** The following cables and raceways shall be permitted in metal raceways in a riser having firestops at each floor:

- (1) Types CMP, CMR, CMG, CM, and CMX cables
- (2) Plenum, riser, and general-purpose communications raceways
- (3) Types CMP, CMR, CMG, CM, and CMX cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway

Informational Note: See 800.26 for firestop requirements for floor penetrations.

**(F) Risers — Cables and Raceways in Fireproof Shafts.** The following cables and raceways shall be permitted to be installed in fireproof riser shafts having firestops at each floor:

- (1) Types CMP, CMR, CMG, CM, and CMX cables
- (2) Plenum, riser, and general-purpose communications raceways
- (3) Types CMP, CMR, CMG, and CM cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

Informational Note: See 800.26 for firestop requirements for floor penetrations.

**(G) Risers — One- and Two-Family Dwellings.** The following cables and raceways shall be permitted in one- and two-family dwellings:

- (1) Types CMP, CMR, CMG, and CM cables
- (2) Type CMX cable less than 6 mm (0.25 in.) in diameter
- (3) Plenum, riser, and general-purpose communications raceways
- (4) Types CMP, CMR, CMG, and CM cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

**(H) Cable Trays.** The following wires, cables, and raceways shall be permitted to be supported by cable trays:

- (1) Types CMP, CMR, CMG, and CM cables
- (2) Plenum, riser, and general-purpose communications raceways

- (3) Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
- Plenum communications raceway
  - Riser communications raceway
  - General-purpose communications raceway

**(I) Distributing Frames and Cross-Connect Arrays.**

The following wires, cables, and raceways shall be permitted to be installed in distributing frames and cross-connect arrays:

- Types CMP, CMR, CMG, and CM cables and communications wires
- Plenum, riser, and general-purpose communications raceways
- Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
  - Plenum communications raceway
  - Riser communications raceway
  - General-purpose communications raceway
  - Riser cable routing assembly
  - General-purpose cable routing assembly

**(J) Other Building Locations.** The following wires, cables, and raceways shall be permitted to be installed in building locations other than the locations covered in 800.113(B) through (I):

- Types CMP, CMR, CMG, and CM cables
- A maximum of 3 m (10 ft) of exposed Type CMX in nonconcealed spaces
- Plenum, riser, and general-purpose communications raceways
- Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
  - Plenum communications raceway
  - Riser communications raceway
  - General-purpose communications raceway
- Types CMP, CMR, CMG, and CM cables installed in:
  - Riser cable routing assembly
  - General-purpose cable routing assembly
- Communications wires and Types CMP, CMR, CMG, CM, and CMX cables installed in a raceway of a type recognized in Chapter 3
- Type CMUC undercarpet communications wires and cables installed under carpet

**(K) Multifamily Dwellings.** The following cables, raceways, and wiring assemblies shall be permitted to be installed in multifamily dwellings in locations other than the locations covered in 800.113(B) through (G):

- Types CMP, CMR, CMG, and CM cables
- Type CMX cable less than 6 mm (0.25 in.) in diameter in nonconcealed spaces
- Plenum, riser, and general-purpose communications raceways
- Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
  - Plenum communications raceway
  - Riser communications raceway
  - General-purpose communications raceway
- Types CMP, CMR, CMG, and CM cables installed in:
  - Riser cable routing assembly
  - General-purpose cable routing assembly
- Communications wires and Types CMP, CMR, CMG, CM, and CMX cables installed in a raceway of a type recognized in Chapter 3
- Type CMUC undercarpet communications wires and cables installed under carpet

**(L) One- and Two-Family Dwellings.** The following cables and raceways shall be permitted to be installed in one- and two-family dwellings in locations other than the locations covered in 800.113(B) through (F):

- Types CMP, CMR, CMG, and CM cables
- Type CMX cable less than 6 mm (0.25 in.) in diameter
- Plenum, riser, and general-purpose communications raceways
- Communications wires and Types CMP, CMR, CMG, and CM cables installed in:
  - Plenum communications raceway
  - Riser communications raceway
  - General-purpose communications raceway
- Types CMP, CMR, CMG, and CM cables installed in:
  - Riser cable routing assembly
  - General-purpose cable routing assembly
- Communication wires and Types CMP, CMR, CMG, CM, and CMX cables installed in a raceway of a type recognized in Chapter 3
- Type CMUC undercarpet communications wires and cables installed under carpet
- Hybrid power and communications cable listed in accordance with 800.179(I)

### 800.133 Installation of Communications Wires, Cables, and Equipment

Communications wires and cables from the protector to the equipment or, where no protector is required, communications wires and cables attached to the outside or inside of the building shall comply with 800.133(A) through (C).

**(A) Separation from Other Conductors.****(1) In Raceways, Cable Trays, Boxes, Cables, and Enclosures.**

(a) *Optical Fiber and Communications Cables.* Communications cables shall be permitted in the same raceway, cable tray, enclosure, or cable routing assembly with cables of any of the following:

- (1) Nonconductive and conductive optical fiber cables in compliance with Parts I and IV of Article 770
- (2) Community antenna television and radio distribution systems in compliance with Parts I and IV of Article 820
- (3) Low-power network-powered broadband communications circuits in compliance with Parts I and IV of Article 830

(b) *Other Circuits.* Communications cables shall be permitted in the same raceway, cable tray, or enclosure with cables of any of the following:

- (1) Class 2 and Class 3 remote-control, signaling, and power-limited circuits in compliance with Parts I and III of Article 725
- (2) Power-limited fire alarm systems in compliance with Parts I and III of Article 760

(c) *Class 2 and Class 3 Circuits.* Class 1 circuits shall not be run in the same cable with communications circuits. Class 2 and Class 3 circuit conductors shall be permitted in the same cable with communications circuits, in which case the Class 2 and Class 3 circuits shall be classified as communications circuits and shall meet the requirements of this article. The cables shall be listed as communications cables.

*Exception:* Cables constructed of individually listed Class 2, Class 3, and communications cables under a common jacket shall not be required to be classified as communications cable. The fire-resistance rating of the composite cable shall be determined by the performance of the composite cable.

(d) *Electric Light, Power, Class 1, Non-Power-Limited Fire Alarm, and Medium-Power Network-Powered Broadband Communications Circuits in Raceways, Compartments, and Boxes.* Communications conductors shall not be placed in any raceway, compartment, outlet box, junction box, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm, or medium-power network-powered broadband communications circuits.

*Exception No. 1:* Where all of the conductors of electric light, power, Class 1, non-power-limited fire alarm, and

medium-power network-powered broadband communications circuits are separated from all of the conductors of communications circuits by a permanent barrier or listed divider.

This exception recognizes the use of a listed field-installed divider to separate the communications circuits from the power circuits.

*Exception No. 2:* Power conductors in outlet boxes, junction boxes, or similar fittings or compartments where such conductors are introduced solely for power supply to communications equipment. The power circuit conductors shall be routed within the enclosure to maintain a minimum of 6 mm (0.25 in.) separation from the communications circuit conductors.

*Exception No. 3:* As permitted by 620.36.

**(2) Other Applications.** Communications wires and cables shall be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, non-power-limited fire alarm, or medium-power network-powered broadband communications circuits.

*Exception No. 1:* Where either (1) all of the conductors of the electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits are in a raceway or in metal-sheathed, metal-clad, nonmetallic-sheathed, Type AC, or Type UF cables, or (2) all of the conductors of communications circuits are encased in raceway.

*Exception No. 2:* Where the communications wires and cables are permanently separated from the conductors of electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the wire.

**(B) Support of Communications Wires and Cables.** Raceways shall be used for their intended purpose. Communications wires and cables shall not be strapped, taped, or attached by any means to the exterior of any raceway as a means of support.

Section 800.24 requires that communications cable be supported by the building structure in such a manner that the cable will not be damaged by ordinary building use.

*Exception: Overhead (aerial) spans of communications wires and cables shall be permitted to be attached to the exterior of a raceway-type mast intended for the attachment and support of such wires and cables.*

In some instances, the only way to achieve the proper clearance above roadways, driveways, or structures is by use of a mast. The exception to 800.133(B) permits overhead spans of communications cable to be attached to the exterior of a raceway-type mast only if the mast is installed to support communications cable. Section 230.28 prohibits the attachment of communications cable to a service mast.

### 800.154 Applications of Listed Communications Wires, Cables, and Raceways

Permitted and nonpermitted applications of listed communications wires, cables, and raceways shall be as indicated in Table 800.154(a). The permitted applications shall be subject to the installation requirements of 800.110 and 800.113. The substitutions for communications cables listed in Table 800.154(b) and illustrated in Figure 800.154 shall be permitted.

Note that the length of unlisted outside-plant cable permitted in a building depends on the location of the primary protector, in accordance with 800.48 and 800.90(B).

**TABLE 800.154(a) Applications of Listed Communications Wires, Cables, and Raceways in Buildings**

	In general-purpose communications raceways and general-purpose cable routing assemblies	Y*	Y*	Y*	N	N	N	Y*			

Note: An “N” in the table indicates that the cable type is not permitted to be installed in the application. A “Y\*” indicates that the cable is permitted to be installed in the application, subject to the limitations described in 800.110 and 800.113.

Informational Note 1: Part V of Article 800 covers installation methods within buildings. This table covers the applications of listed communications wires, cables and raceways in buildings. The definition of point of entrance is in 800.2. Communications entrance cables that have not emerged from the rigid metal conduit or intermediate metal conduit are not considered to be in the building.

Informational Note No. 2: For information on the restrictions to the installation of communications cables in fabricated ducts see 800.113(B).

Cable Type	Permitted Substitutions
CMR	CMP
CMG, CM	CMP, CMR
CMX	CMP, CMR, CMG, CM

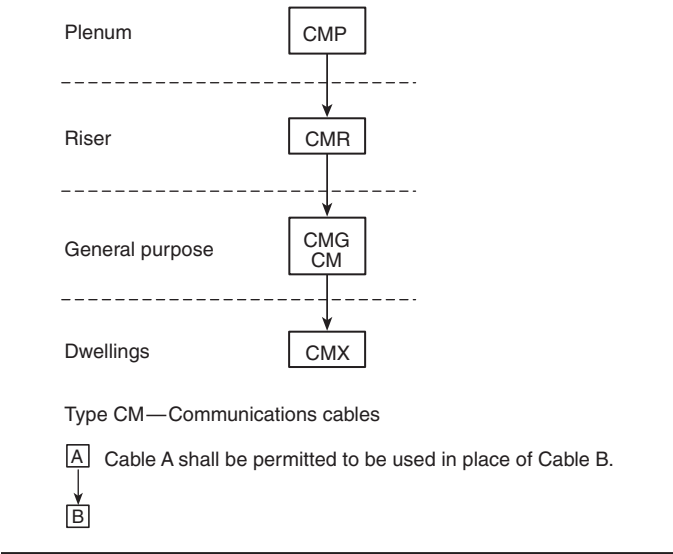

FIGURE 800.154 Cable Substitution Hierarchy.

Exhibit 800.5 illustrates applications of listed communications cables.

Table 800.154(a) provides a summary of applications for the wire, cable, and raceway types covered in Article 800. Note that the permitted applications are a summary and are subject to the installation requirements of 800.110 and 800.113.

800.156 Dwelling Unit Communications Outlet

For new construction, a minimum of one communications outlet shall be installed within the dwelling in a readily accessible area and cabled to the service provider demarcation point.

This requirement applies to all dwelling units, including those in two-family and multifamily dwellings (see the definitions of *dwelling* and *dwelling unit* in Article 100). The location of the communications outlet within a dwelling is not specified, but cable must be installed between the outlet location and the point at which the communication services provider installs its equipment or the point at which it connects to owner-supplied equipment. Although the use of cellular or PCS telephones is extremely common today and an increasing number of dwelling unit owners or occupants

EXHIBIT 800.5 Applications of listed communications cables within various locations of a building.

may use that type of communication service exclusively, having at least one wired communications outlet in every dwelling facilitates connection of dial-up devices used in home fire detection and security systems. Exhibit 800.6 illustrates the provisions for a communications outlet provided during the “rough-in” phase of a dwelling’s electrical installation.

**EXHIBIT 800.6** Communications outlet provision installed at “rough-in.” (Courtesy of the International Association of Electrical Inspectors)

## VI. Listing Requirements

### 800.170 Equipment

Communications equipment shall be listed as being suitable for electrical connection to a communications network.

Informational Note: One way to determine applicable requirements is to refer to UL 60950-1-2003, *Standard for Safety of Information Technology Equipment*; UL 1459-1995, *Standard for Safety, Telephone Equipment*; or UL 1863-2004, *Standard for Safety, Communications Circuit Accessories*. For information on listing requirements for communications raceways, see UL 2024-2004, *Standard for Optical Fiber and Communication Cable Raceways*.

**(A) Primary Protectors.** The primary protector shall consist of an arrester connected between each line conductor and ground in an appropriate mounting. Primary protector terminals shall be marked to indicate line and ground as applicable.

Informational Note: One way to determine applicable requirements for a listed primary protector is to refer to ANSI/UL 497-1995, *Standard for Protectors for Paired Conductor Communications Circuits*.

**(B) Secondary Protectors.** The secondary protector shall be listed as suitable to provide means to safely limit currents to less than the current-carrying capacity of listed indoor communications wire and cable, listed telephone set line cords, and listed communications terminal equipment having ports for external wire line communications circuits. Any overvoltage protection, arresters, or grounding connection shall be connected on the equipment terminals side of the secondary protector current-limiting means.

Informational Note: One way to determine applicable requirements for a listed secondary protector is to refer to UL 497A-1996, *Standard for Secondary Protectors for Communications Circuits*.

### 800.173 Drop Wire and Cable

Communications wires and cables without a metallic shield, running from the last outdoor support to the primary protector, shall be listed as being suitable for the purpose and shall have current-carrying capacity as specified in 800.90(A)(1)(b) or (A)(1)(c).

### 800.179 Communications Wires and Cables

Communications wires and cables shall be listed in accordance with 800.179(A) through (I) and marked in accordance with Table 800.179. Conductors in communications cables, other than in a coaxial cable, shall be copper.

Communications wires and cables shall have a voltage rating of not less than 300 volts. The insulation for the individual conductors, other than the outer conductor of a coaxial cable, shall be rated for 300 volts minimum. The cable voltage rating shall not be marked on the cable or on the undercarpet communications wire. Communications wires and cables shall have a temperature rating of not less than 60°C.

Section 800.179 requires a conductor insulation rating of 300 volts for the following reasons:

1. To coordinate with protector installation requirements (i.e., protectors are not required within a block unless the cable is exposed to over 300 volts)
2. To recognize the fact that primary protectors are designed to allow voltages below 300 to pass
3. To accommodate the voltages ordinarily found on a telephone line (48 volts dc plus ringing voltage up to 130 volts rms)
4. To permit communications cable to substitute for 300-volt power-limited fire-protective signaling cable

*Exception: Voltage markings shall be permitted where the cable has multiple listings and voltage marking is required for one or more of the listings.*

Informational Note No. 1: Voltage markings on cables may be misinterpreted to suggest that the cables may be suitable for Class 1, electric light, and power applications.

Informational Note No. 2: See 800.170 for listing requirement for equipment.

**TABLE 800.179 Cable Markings**

Cable Marking	Type
CMP	Communications plenum cable
CMR	Communications riser cable
CMG	Communications general-purpose cable
CM	Communications general-purpose cable
CMX	Communications cable, limited use
CMUC	Undercarpet communications wire and cable

Informational Note: Cable types are listed in descending order of fire resistance rating.

**(A) Type CMP.** Type CMP communications plenum cables shall be listed as being suitable for use in ducts, plenums, and other spaces used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

See the commentary following the informational note to 725.179(A).

**(B) Type CMR.** Type CMR communications riser cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2002, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

See the commentary following the informational note to 725.179(B).

**(C) Type CMG.** Type CMG general-purpose communications cables shall be listed as being suitable for general-purpose communications use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

See the commentary following the informational note to 725.179(C).

**(D) Type CM.** Type CM communications cables shall be listed as being suitable for general-purpose communications use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Flame Tray Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

See the commentary following the informational note to 725.179(D).

**(E) Type CMX.** Type CMX limited-use communications cables shall be listed as being suitable for use in dwellings and for use in raceway and shall also be listed as being resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical-wire) flame test in ANSI/UL 1581-2001, *Reference Standard for Electrical Wires, Cables and Flexible Cords*.

**(F) Type CMUC Undercarpet Wires and Cables.** Type CMUC undercarpet communications wires and cables shall be listed as being suitable for undercarpet use and shall also be listed as being resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical-wire) flame test in ANSI/UL 1581-1991,

*Reference Standard for Electrical Wires, Cables and Flexible Cords.*

**(G) Communications Circuit Integrity (CI) Cables.** Cables suitable for use in communications systems to ensure survivability of critical circuits during a specified time under fire conditions shall be listed as circuit integrity (CI) cable. Cables identified in 800.179(A) through (E) that meet the requirements for circuit integrity shall have the additional classification using the suffix “CI.”

Informational Note: One method of defining circuit integrity (CI) cable is by establishing a minimum 2-hour fire resistance rating for the cable when tested in accordance with UL 2196-1995, *Standard for Tests of Fire Resistive Cables*.

**(H) Communications Wires.** Communications wires, such as distributing frame wire and jumper wire, shall be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Flame Tray Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

**(I) Hybrid Power and Communications Cables.** Listed hybrid power and communications cables shall be permitted where the power cable is a listed Type NM or NM-B conforming to the provisions of Article 334, and the communications cable is a listed Type CM, the jackets on the listed NM or NM-B and listed CM cables are rated for 600 volts minimum, and the hybrid cable is listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Flame Tray Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

## 800.182 Communications Raceways and Cable Routing Assemblies

Communications raceways shall be listed in accordance with 800.182(A) through (C).

**(A) Plenum Communications Raceways.** Plenum communications raceways listed as plenum optical fiber raceways shall be permitted for use in ducts, plenums, and other spaces used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining that an optical fiber raceway is a low smoke producing raceway and a fire-resistant raceway is that the raceway exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with the plenum test in UL 2024-2004, *Standard for Optical Fiber Cable Raceway*.

**(B) Riser Communications Raceways and Cable Routing Assemblies.** Riser communications raceways and riser cable routing assemblies shall be listed as having adequate fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the raceways pass the requirements of the test for Flame Propagation (riser) in UL 2024-2004, *Standard for Optical Fiber Cable Raceway*, or UL 2024a-2008, *Outline of Investigation for Optical Fiber Cable Routing Assemblies*, as applicable.

**(C) General-Purpose Communications Raceways and Cable Routing Assemblies.** General-purpose communications raceways and cable routing assemblies shall be listed as being resistant to the spread of fire.

Informational Note: One method of defining resistance to the spread of fire is that the raceways pass the requirements of the Vertical-Tray Flame Test (General Use) in UL 2024-2004, *Standard for Optical Fiber Cable Raceway*, or UL 2024a-2008, *Outline of Investigation for Optical Fiber Cable Routing Assemblies*, as applicable.

The communications raceways covered in 800.182(A) through (C) are listed raceways used in plenum, riser, or general-purpose applications. This listing includes raceways and fittings for the installation of communications cable in accordance with Article 800. These raceways are not suitable for installation of wires, cords, or cabling with or without communications members.

A raceway marked “plenum” is suitable for use in ducts, plenums, or other spaces used for environmental air in accordance with 800.154 where used to enclose communications cable marked CMP. This raceway exhibits a maximum peak optical density of 0.5, a maximum average optical density of 0.15, and a maximum flame-spread distance of 5 ft when tested in accordance with UL 2024, *Standard for*

**Optical-Fiber Cable Raceway.** This raceway is identified by a marking on its surface or on a marker tape indicating “plenum.” A raceway marked “plenum” is also suitable for installation in risers when used to enclose communications cable marked CMP or CMR; for general-purpose use when used to enclose communications cable marked CMP, CMR, CMG, or CM; and for dwellings when used to enclose communications cable marked CMP, CMR, CMG, CM, or CMX.

A raceway marked “riser” is suitable for installation in risers in accordance with 800.154 when used to enclose communications cable marked CMP or CMR. This raceway has fire-resistant characteristics capable of preventing the carrying of fire from floor to floor, and it meets the test requirements of UL 2024, *Standard for Optical-Fiber Cable Raceway*. This raceway is identified by a marking on its surface or on a marker tape indicating “riser.” A raceway marked “riser” is also suitable for general-purpose use when used to enclose communications cable marked CMP, CMR, CMG, or CM, and for dwellings when used to enclose communications cable marked CMP, CMR, CMG, CM, or CMX.

A raceway marked “general purpose” is suitable for installation in general-purpose areas in accordance with 800.154 when used to enclose communications cable marked CMP, CMR, CMG, or CM, and for dwellings when used to enclose communications cable marked CMP, CMR, CMG, CM, or CMX.

Pliable raceway is raceway that can be bent by hand without the use of tools. The smallest radius of the curve of the inner edge of any bend to which the raceway can be bent without cracking either on the outer surface or internally is not less than 2½ times the outside diameter of the raceway.

Informational Note: The general term *grounding conductor* as previously used in this article is replaced by either the term *bonding conductor* or the term *grounding electrode conductor* (GEC), where applicable, to more accurately reflect the application and function of the conductor.

This informational note explains the revision of the term *grounding conductor* to *bonding conductor* and *grounding electrode conductor* throughout Article 810.

This informational note and Figures 800(a) and 800(b) explain how the new, more precise terms (*bonding conductor* and *grounding electrode conductor*) are implemented in the requirements that formerly used the term *grounding conductor*. The figures are located in Article 800, but the concepts depicted are applicable in Article 810.

## I. General

### 810.1 Scope

This article covers antenna systems for radio and television receiving equipment, amateur and citizen band radio transmitting and receiving equipment, and certain features of transmitter safety. This article covers antennas such as *wire-strung type*, multi-element, vertical rod, and dish and also covers the wiring and cabling that connects them to equipment. This article does not cover equipment and antennas used for coupling carrier current to power line conductors.

Article 810 covers wiring requirements for television and radio receiving equipment, specifically including digital satellite receiving equipment for television signals, and wiring for amateur radio equipment and citizens band (CB) radio equipment. Chapters 1 through 4 cover wiring for the power supply. Article 640 contains requirements for sound distribution systems. The interior wiring of coaxial cable is covered by Article 820.

In accordance with 90.3, the articles in Chapter 8 are not subject to the requirements contained in the other articles of the *Code* unless specifically referenced.

### 810.2 Definitions

For definitions applicable to this article, see Article 100.

### 810.3 Other Articles

Wiring from the source of power to and between devices connected to the interior wiring system shall comply with Chapters 1 through 4 other than as modified by Parts I and II of Article 640. Wiring for audio signal processing, amplification, and reproduction equipment shall comply with Article 640. Coaxial cables that connect antennas to equipment shall comply with Article 820.

### 810.4 Community Television Antenna

The antenna shall comply with this article. The distribution system shall comply with Article 820.

### 810.5 Radio Noise Suppressors

Radio interference eliminators, interference capacitors, or noise suppressors connected to power-supply leads shall be of a listed type. They shall not be exposed to physical damage.

## II. Receiving Equipment — Antenna Systems

### 810.11 Material

Antennas and lead-in conductors shall be of hard-drawn copper, bronze, aluminum alloy, copper-clad steel, or other high-strength, corrosion-resistant material.

*Exception: Soft-drawn or medium-drawn copper shall be permitted for lead-in conductors where the maximum span between points of support is less than 11 m (35 ft).*

### 810.12 Supports

Outdoor antennas and lead-in conductors shall be securely supported. The antennas or lead-in conductors shall not be attached to the electric service mast. They shall not be attached to poles or similar structures carrying open electric light or power wires or trolley wires of over 250 volts between conductors. Insulators supporting the antenna conductors shall have sufficient mechanical strength to safely support the conductors. Lead-in conductors shall be securely attached to the antennas.

### 810.13 Avoidance of Contacts with Conductors of Other Systems

Outdoor antennas and lead-in conductors from an antenna to a building shall not cross over open conductors of electric light or power circuits and shall be kept well away from all such circuits so as to avoid the possibility of accidental contact. Where proximity to open electric light or power service conductors of less than 250 volts between conductors cannot be avoided, the installation shall be such as to provide a clearance of at least 600 mm (2 ft).

Where practicable, antenna conductors shall be installed so as not to cross under open electric light or power conductors.

One of the leading causes of electric shock and electrocution, according to statistical reports, is the accidental contact of antennas, ladders, and other equipment with overhead light or power conductors. Extreme caution should be exercised during this type of installation, and periodic visual inspections should be conducted thereafter.

810.14 Splices

Splices and joints in antenna spans shall be made mechanically secure with approved splicing devices or by such other means as will not appreciably weaken the conductors.

Section 810.14 requires that splices and joints be made with approved connectors or other means that provide sufficient mechanical strength so that conductors are not weakened appreciably, a condition that could cause them to break and come into contact with higher-voltage conductors. Conductor spans from antennas of sufficient size and strength to maintain clearances and avoid possible contact with light or power conductors.

810.15 Grounding

Masts and metal structures supporting antennas shall be grounded in accordance with 810.21.

810.16 Size of Wire-Strung Antenna — Receiving Station

(A) **Size of Antenna Conductors.** Outdoor antenna conductors for receiving stations shall be of a size not less than given in Table 810.16(A).

TABLE 810.16(A) Size of Receiving Station Outdoor Antenna Conductors

Material	Minimum Size of Conductors (AWG) Where Maximum Open Span Length Is		
	Less Than 11 m (35 ft)	11 m to 45 m (35 ft to 150 ft)	Over 45 m (150 ft)
Aluminum alloy, hard-drawn copper	19	14	12
Copper-clad steel, bronze, or other high-strength material	20	17	14

(B) **Self-Supporting Antennas.** Outdoor antennas, such as vertical rods, dishes, or dipole structures, shall be of corrosion-resistant materials and of strength suitable to withstand ice and wind loading conditions and shall be located well away from overhead conductors of electric light and power circuits of over 150 volts to ground, so as to avoid the possibility of the antenna or structure falling into or making accidental contact with such circuits.

The requirements of 810.16(B) include dish-type (parabolic) antennas.

810.17 Size of Lead-in — Receiving Station

Lead-in conductors from outside antennas for receiving stations shall, for various maximum open span lengths, be of such size as to have a tensile strength at least as great as that of the conductors for antennas as specified in 810.16. Where the lead-in consists of two or more conductors that are twisted together, are enclosed in the same covering, or are concentric, the conductor size shall, for various maximum open span lengths, be such that the tensile strength of the combination is at least as great as that of the conductors for antennas as specified in 810.16.

810.18 Clearances — Receiving Stations

(A) **Outside of Buildings.** Lead-in conductors attached to buildings shall be installed so that they cannot swing closer than 600 mm (2 ft) to the conductors of circuits of 250 volts or less between conductors, or 3.0 m (10 ft) to the conductors of circuits of over 250 volts between conductors, except that in the case of circuits not over 150 volts between conductors, where all conductors involved are supported so as to ensure permanent separation, the clearance shall be permitted to be reduced but shall not be less than 100 mm (4 in.). The clearance between lead-in conductors and any conductor forming a part of a lightning protection system shall not be less than 1.8 m (6 ft). Underground conductors shall be separated at least 300 mm (12 in.) from conductors of any light or power circuits or Class 1 circuits.

*Exception: Where the electric light or power conductors, Class 1 conductors, or lead-in conductors are installed in raceways or metal cable armor.*

Informational Note No. 1: See 250.60 for use of air terminals. For further information, see NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*, which contains detailed information on grounding, bonding, and spacing from lightning protection systems.

Informational Note No. 2: Metal raceways, enclosures, frames, and other non-current-carrying metal parts of electrical equipment installed on a building equipped with a lightning protection system may require bonding or spacing from the lightning protection conductors in accordance with NFPA 780-2011, *Standard for the Installation of Lightning Protection Systems*. Separation from lightning protection conductors is typically 1.8 m (6 ft) through air or 900 mm (3 ft) through dense materials such as concrete, brick, or wood.

(B) **Antennas and Lead-ins — Indoors.** Indoor antennas and indoor lead-ins shall not be run nearer than 50 mm (2 in.) to conductors of other wiring systems in the premises.

*Exception No. 1: Where such other conductors are in metal raceways or cable armor.*

*Exception No. 2: Where permanently separated from such other conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing.*

**(C) In Boxes or Other Enclosures.** Indoor antennas and indoor lead-ins shall be permitted to occupy the same box or enclosure with conductors of other wiring systems where separated from such other conductors by an effective permanently installed barrier.

### 810.19 Electrical Supply Circuits Used in Lieu of Antenna — Receiving Stations

Where an electrical supply circuit is used in lieu of an antenna, the device by which the radio receiving set is connected to the supply circuit shall be listed.

The approved connecting device is usually a small, fixed capacitor connecting the antenna terminal of the receiver and one wire of the supply circuit. As is the case with most receivers, the capacitor should be designed for operation at not less than 300 volts. This voltage rating ensures a high degree of safety and minimizes the possibility of a breakdown in the capacitor, thereby avoiding a short circuit to ground through the antenna coil of the set.

### 810.20 Antenna Discharge Units — Receiving Stations

**(A) Where Required.** Each conductor of a lead-in from an outdoor antenna shall be provided with a listed antenna discharge unit.

*Exception: Where the lead-in conductors are enclosed in a continuous metallic shield that either is grounded with a conductor in accordance with 810.21 or is protected by an antenna discharge unit.*

An antenna discharge unit (lightning arrester) is not required if the lead-in conductors are enclosed in a continuous metal shield, such as rigid or intermediate metal conduit, electrical metallic tubing, or any metal raceway or metal-shielded cable that is effectively grounded. A lightning discharge will take the path of lower impedance and jump from the lead-in conductors to the metal raceway or shield rather than take the path through the antenna coil of the receiver.

**(B) Location.** Antenna discharge units shall be located outside the building or inside the building between the point of entrance of the lead-in and the radio set or transformers and as near as practicable to the entrance of the conductors to the

building. The antenna discharge unit shall not be located near combustible material or in a hazardous (classified) location as defined in Article 500.

**(C) Grounding.** The antenna discharge unit shall be grounded in accordance with 810.21.

### 810.21 Bonding Conductors and Grounding Electrode Conductors — Receiving Stations

Bonding conductors or grounding electrode conductors shall comply with 810.21(A) through (K).

**(A) Material.** The bonding conductor or grounding electrode conductor shall be of copper, aluminum, copper-clad steel, bronze, or similar corrosion-resistant material. Aluminum or copper-clad aluminum bonding conductors or grounding electrode conductors shall not be used where in direct contact with masonry or the earth or where subject to corrosive conditions. Where used outside, aluminum or copper-clad aluminum conductors shall not be installed within 450 mm (18 in.) of the earth.

**(B) Insulation.** Insulation on bonding conductors or grounding electrode conductors shall not be required.

**(C) Supports.** The bonding conductors and grounding electrode conductors shall be securely fastened in place and shall be permitted to be directly attached to the surface wired over without the use of insulating supports.

*Exception: Where proper support cannot be provided, the size of the bonding conductors and grounding electrode conductors shall be increased proportionately.*

**(D) Mechanical Protection.** The bonding conductors and grounding electrode conductor shall be protected where exposed to physical damage. Where the bonding conductor or grounding electrode conductor is run in a metal raceway, both ends of the raceway shall be bonded to the contained conductor or to the same terminal or electrode to which the conductor is connected.

If metal enclosures such as steel conduit are used to enclose the grounding electrode conductor, a connection between the grounding electrode conductor and the metal conduit must be provided at both ends of the conduit to provide an adequate low-impedance current path to ground.

**(E) Run in Straight Line.** The bonding conductor or grounding electrode conductor for an antenna mast or antenna discharge unit shall be run in as straight a line as practicable.

**(F) Electrode.** The bonding conductor or grounding electrode conductor shall be connected as required in (F)(1) through (F)(3).

**(1) In Buildings or Structures with an Intersystem Bonding Termination.** If the building or structure served has an intersystem bonding termination as required by 250.94, the bonding conductor shall be connected to the intersystem bonding termination.

Informational Note: See Article 100 for the definition of *Intersystem Bonding Termination*.

**(2) In Buildings or Structures with Grounding Means.** If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on the following:

- (1) The building or structure grounding electrode system as covered in 250.50
- (2) The grounded interior metal water piping systems, within 1.52 m (5 ft) from its point of entrance to the building, as covered in 250.52

For more information on the use of a metal water piping system, see the commentary following 250.52(A)(1).

- (3) The power service accessible means external to the building, as covered in 250.94
- (4) The nonflexible metallic power service raceway
- (5) The service equipment enclosure, or
- (6) The grounding electrode conductor or the grounding electrode conductor metal enclosures of the power service

A bonding device intended to provide a termination point for the bonding conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on non-removable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is non-removable.

**(3) In Buildings or Structures Without an Intersystem Bonding Termination or Grounding Means.** If the building or structure served has no intersystem bonding termination or grounding means as described in 810.21(F)(2), the grounding electrode conductor shall be connected to an electrode as described in 250.52.

**(G) Inside or Outside Building.** The bonding conductor or grounding electrode conductor shall be permitted to be run either inside or outside the building.

**(H) Size.** The bonding conductor or grounding electrode conductor shall not be smaller than 10 AWG copper, 8 AWG aluminum, or 17 AWG copper-clad steel or bronze.

**(I) Common Ground.** A single bonding conductor or grounding electrode conductor shall be permitted for both protective and operating purposes.

**(J) Bonding of Electrodes.** A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the radio and television equipment grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

The requirements for grounding are in accordance with Article 250. Antenna masts must be grounded to the same grounding electrode used for the building's electrical system, to ensure that all exposed, non-current-carrying metal parts are at the same potential. In many cases, masts are connected incorrectly to conveniently located vent pipes, metal gutters, or downspouts. Such a connection could create potential differences between lead-in conductors and various metal parts located in or on buildings, resulting in possible shock and fire hazards. An underground gas piping system is not permitted to be used as a grounding electrode.

The use of separate radio/television grounding electrodes is not required. However, where they are provided, 800.21(J) requires the radio/television system grounding electrode to be connected, via a bonding jumper, to the grounding electrode of the electrical distribution system of the building or structure.

**(K) Electrode Connection.** Connections to grounding electrodes shall comply with 250.70.

This requirement is similar to the requirements for grounding electrode conductors in Articles 800, 820, and 830.

### III. Amateur and Citizen Band Transmitting and Receiving Stations — Antenna Systems

#### 810.51 Other Sections

In addition to complying with Part III, antenna systems for amateur and citizen band transmitting and receiving stations shall also comply with 810.11 through 810.15.

Amateur radio and citizens band (CB) radio are two different noncommercial radio services. From the standpoint of the NEC, the installation requirements are similar.

### 810.52 Size of Antenna

Antenna conductors for transmitting and receiving stations shall be of a size not less than given in Table 810.52.

**TABLE 810.52 Size of Outdoor Antenna Conductors**

Material	Minimum Size of Conductors (AWG) Where Maximum Open Span Length Is	
	Less Than 45 m (150 ft)	Over 45 m (150 ft)
Hard-drawn copper	14	10
Copper-clad steel, bronze, or other high-strength material	14	12

### 810.53 Size of Lead-in Conductors

Lead-in conductors for transmitting stations shall, for various maximum span lengths, be of a size at least as great as that of conductors for antennas as specified in 810.52.

### 810.54 Clearance on Building

Antenna conductors for transmitting stations, attached to buildings, shall be firmly mounted at least 75 mm (3 in.) clear of the surface of the building on nonabsorbent insulating supports, such as treated pins or brackets equipped with insulators having not less than 75-mm (3-in.) creepage and airgap distances. Lead-in conductors attached to buildings shall also comply with these requirements.

*Exception: Where the lead-in conductors are enclosed in a continuous metallic shield that is grounded with a conductor in accordance with 810.58, they shall not be required to comply with these requirements. Where grounded, the metallic shield shall also be permitted to be used as a conductor.*

Section 810.54 specifies the minimum creepage and air gap distances for conductors attached to buildings. Creepage distance is measured from the conductor across the face of the supporting insulator to the building surface. Air gap distance is measured from the conductor (at its closest point) across the air space (not necessarily in a straight line) to the surface of the building. The exception covers coaxial cable with the shield permanently and effectively grounded.

### 810.55 Entrance to Building

Except where protected with a continuous metallic shield that is grounded with a conductor in accordance with 810.58, lead-in conductors for transmitting stations shall enter buildings by one of the following methods:

- (1) Through a rigid, noncombustible, nonabsorbent insulating tube or bushing
- (2) Through an opening provided for the purpose in which the entrance conductors are firmly secured so as to provide a clearance of at least 50 mm (2 in.)
- (3) Through a drilled window pane

### 810.56 Protection Against Accidental Contact

Lead-in conductors to radio transmitters shall be located or installed so as to make accidental contact with them difficult.

### 810.57 Antenna Discharge Units — Transmitting Stations

Each conductor of a lead-in for outdoor antennas shall be provided with an antenna discharge unit or other suitable means that drain static charges from the antenna system.

*Exception No. 1: Where the lead-in is protected by a continuous metallic shield that is grounded with a conductor in accordance with 810.58, an antenna discharge unit or other suitable means shall not be required.*

*Exception No. 2: Where the antenna is grounded with a conductor in accordance with 810.58, an antenna discharge unit or other suitable means shall not be required.*

If an antenna discharge unit is not installed at a transmitting station, protection against lightning may be provided by a switch that connects the lead-in conductors to ground during the times the station is not in operation.

### 810.58 Bonding Conductors and Grounding Electrode Conductors — Amateur and Citizen Band Transmitting and Receiving Stations

Bonding conductors and grounding electrode conductors shall comply with 810.58(A) through (C).

**(A) Other Sections.** All bonding conductors and grounding electrode conductors for amateur and citizen band transmitting and receiving stations shall comply with 810.21(A) through (K).

**(B) Size of Protective Bonding Conductor or Grounding Electrode Conductor.** The protective bonding conductor or grounding electrode conductor for transmitting stations shall be as large as the lead-in but not smaller than 10 AWG copper, bronze, or copper-clad steel.

**(C) Size of Operating Bonding Conductor or Grounding Electrode Conductor.** The operating bonding conductor or grounding electrode conductor for transmitting

stations shall not be less than 14 AWG copper or its equivalent.

## IV. Interior Installation — Transmitting Stations

### 810.70 Clearance from Other Conductors

All conductors inside the building shall be separated at least 100 mm (4 in.) from the conductors of any electric light, power, or signaling circuit.

*Exception No. 1: As provided in Article 640.*

*Exception No. 2: Where separated from other conductors by raceway or some firmly fixed nonconductor, such as porcelain tubes or flexible tubing.*

### 810.71 General

Transmitters shall comply with 810.71(A) through (C).

**(A) Enclosing.** The transmitter shall be enclosed in a metal frame or grille or separated from the operating space by a barrier or other equivalent means, all metallic parts of which are effectively connected to a **bonding or grounding electrode** conductor.

**(B) Grounding of Controls.** All external metal handles and controls accessible to the operating personnel shall be effectively connected to an equipment grounding conductor if the transmitter is powered by the premises wiring system or grounded with a conductor in accordance with 810.21.

**(C) Interlocks on Doors.** All access doors shall be provided with interlocks that disconnect all voltages of over 350 volts between conductors when any access door is opened.

Informational Note: The general term *grounding conductor* as previously used in this article is replaced by either the term *bonding conductor* or the term *grounding electrode conductor* (GEC), where applicable, to more accurately reflect the application and function of the conductor.

This informational note explains the revision of the term *grounding conductor* to *bonding conductor* and *grounding electrode conductor* throughout Article 820.

This informational note and Figures 800(a) and 800(b) explain how the new, more precise terms (*bonding conductor* and *grounding electrode conductor*) are implemented in the requirements that formerly used the term *grounding conductor*. These terms are new to Article 820 but have had long-standing use in other *Code* articles. See Article 100 for their definitions. The figures are located in Article 800, but the concepts depicted are applicable in Article 820.

## I. General

### 820.1 Scope

This article covers coaxial cable distribution of radio frequency signals typically employed in community antenna television (CATV) systems.

Informational Note: See 90.2(B)(4) for installations of CATV and radio distribution systems that are not covered.

Article 820 covers the installation of coaxial cable for the distribution of radio frequency (RF) signals associated with closed-circuit television, cable television, and security television cameras. This article also covers interior coaxial cable for radio and television receiving equipment. Article 830 covers network-powered broadband system installations.

### 820.2 Definitions

See Article 100. For the purposes of this article, the following additional definitions apply.

**Abandoned Coaxial Cable.** Installed coaxial cable that is not terminated at equipment other than a coaxial connector and not identified for future use with a tag.

The definition of *abandoned coaxial cable* applies to 820.25, which requires the removal of accessible abandoned coaxial cable. Abandoned cable increases fire loading unnecessarily and, where installed in plenums, can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 770, 800, and 830.

Informational Note: See Article 100 for a definition of *Equipment*.

**Coaxial Cable.** A cylindrical assembly composed of a conductor centered inside a metallic tube or shield, separated by a dielectric material, and usually covered by an insulating jacket.

**Exposed (to Accidental Contact).** A circuit in such a position that, in case of failure of supports and or insulation, contact with another circuit may result.

Informational Note: See Article 100 for two other definitions of *Exposed*.

**Point of Entrance.** The point within a building at which the coaxial cable emerges from an external wall, from a concrete floor slab, or from a rigid metal conduit (Type RMC) or an intermediate metal conduit (Type IMC) connected by a *bonding conductor* or *grounding electrode conductor* in accordance with 820.100(B).

**Premises.** The land and buildings of a user located on the user side of utility-user network point of demarcation.

### 820.3 Other Articles

Circuits and equipment shall comply with 820.3(A) through (G).

**(A) Hazardous (Classified) Locations.** CATV equipment installed in a location that is classified in accordance with 500.5 and 505.5 shall comply with the applicable requirements of Chapter 5.

**(B) Installation and Use.** The requirements of 110.3 shall apply.

**(C) Installations of Conductive and Nonconductive Optical Fiber Cables.** The requirements of Article 770 shall apply.

**(D) Communications Circuits.** The requirements of Article 800 shall apply.

**(E) Network-Powered Broadband Communications Systems.** The requirements of Article 830 shall apply.

**(F) Premises-Powered Broadband Communications Systems.** The requirements of Article 840 shall apply.

**(G) Alternate Wiring Methods.** The wiring methods of Article 830 shall be permitted to substitute for the wiring methods of Article 820.

Informational Note: Use of Article 830 wiring methods will facilitate the upgrading of Article 820 installations to network-powered broadband applications.

**(H) Cable Routing Assemblies.** The definition in 770.2, the applications in 770.154, and installation rules in 770.113 shall apply to Article 820.

### 820.15 Power Limitations

Coaxial cable shall be permitted to deliver power to equipment that is directly associated with the radio frequency distribution system if the voltage is not over 60 volts and if the current is supplied by a transformer or other device that has power-limiting characteristics.

Power shall be blocked from premises devices on the network that are not intended to be powered via the coaxial cable.

### 820.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of coaxial cables that prevents removal of panels, including suspended ceiling panels.

An excess accumulation of wires and cables can limit access to equipment by preventing the removal of access panels. (See Exhibit 820.1.)

### 820.24 Mechanical Execution of Work

Community television and radio distribution systems shall be installed in a neat and workmanlike manner. Coaxial cables installed exposed on the surface of ceiling and side-walls shall be supported by the building structure in such a manner that the cables will not be damaged by normal building use. Such cables shall be secured by hardware including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11.

**EXHIBIT 820.1** *Incorrect installation of conductors and cables (upper diagram), which can prevent access to equipment or cables. Correct method is shown in lower diagram.*

Section 820.24 provides definitive requirements for workmanship. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable must be carefully evaluated to ensure that activities and processes within the building do not damage the cable. Although this requirement does not contain specific supporting and securing intervals, it does reference 300.11 as a general rule on securing equipment and cables and 300.4(D) for protection of cables installed parallel to framing methods.

Informational Note No. 1: Accepted industry practices are described in ANSI/NECA/BICSI 568–2006, *Standard for Installing Commercial Building Telecommunications Cabling*; ANSI/TIA/EIA-568-B.1 2004 — *Part 1, General Requirements Commercial Building Telecommunications Cabling Standard*; ANSI/TIA-569-B 2004, *Commercial Building Standard for Telecommunications Pathways and Spaces*; ANSI/TIA-570-B, *Residential Telecommunications Infrastructure*, and other ANSI-approved installation standards.

Informational Note No. 2: See NFPA 90A-2009, *Standard for Installation of Air-Conditioning and Ventilating Systems*, for discrete combustible components installed in accordance with 300.22(B) and (C).

### 820.25 Abandoned Cables

The accessible portion of abandoned coaxial cables shall be removed. Where cables are identified for future use with a

tag, the tag shall be of sufficient durability to withstand the environment involved.

This section requires the removal of abandoned coaxial cable that is accessible. See Article 100 for the definition of *accessible*. Abandoned cable increases fire loading unnecessarily, and, where installed in plenums, can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 770, 800, and 830. (Also see the definition of *abandoned coaxial cable* in 820.2.)

## 820.26 Spread of Fire or Products of Combustion

Installations of coaxial cables and CATV raceways in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations of coaxial cables and CATV raceways through fire-resistant-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

**Informational Note:** Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made. Building codes also contain restrictions on membrane penetrations on opposite sides of a fire resistance-rated wall assembly. An example is the 600-mm (24-in.) minimum horizontal separation that usually applies between boxes installed on opposite sides of the wall. Assistance in complying with 820.26 can be found in building codes, fire resistance directories, and product listings.

## II. Coaxial Cables Outside and Entering Buildings

### 820.44 Overhead (Aerial) Coaxial Cables

Overhead (aerial) coaxial cables, prior to the point of grounding, as specified in 820.93, shall comply with 820.44(A) through (E).

**(A) On Poles and In-Span.** Where coaxial cables and electric light or power conductors are supported by the same pole or are run parallel to each other in-span, the conditions described in 820.44(A)(1) through (A)(4) shall be met.

**(1) Relative Location.** Where practicable, the coaxial cables shall be located below the electric light or power conductors.

**(2) Attachment to Cross-Arms.** Coaxial cables shall not be attached to cross-arm that carries electric light or power conductors.

**(3) Climbing Space.** The climbing space through coaxial cables shall comply with the requirements of 225.14(D).

**(4) Clearance.** Lead-in or overhead (aerial) -drop coaxial cables from a pole or other support, including the point of initial attachment to a building or structure, shall be kept away from electric light, power, Class 1, or non-power-limited fire alarm circuit conductors so as to avoid the possibility of accidental contact.

*Exception:* Where proximity to electric light, power, Class 1, or non-power-limited fire alarm circuit conductors cannot be avoided, the installation shall provide clearances of not less than 300 mm (12 in.) from electric light, power, Class 1, or non-power-limited fire alarm circuit conductors. The clearance requirement shall apply at all points along the drop, and it shall increase to 1.0 m (40 in.) at the pole.

**(B) Above Roofs.** Coaxial cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

*Exception No. 1:* Auxiliary buildings such as garages and the like.

*Exception No. 2:* A reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (1) not more than 1.2 m (4 ft) of communications service drop conductors pass above the roof overhang, and (2) they are terminated at a raceway mast or other approved support.

*Exception No. 3:* Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.

**(C) On Masts.** Overhead (aerial) coaxial cables shall be permitted to be attached to an above-the-roof raceway mast that does not enclose or support conductors of electric light or power circuits.

**(D) Between Buildings.** Coaxial cables extending between buildings or structures, and also the supports or attachment fixtures, shall be identified for the purpose and shall have sufficient strength to withstand the loads to which they might be subjected.

Wind and ice loads should be considered because they can damage cables and attachment points.

*Exception:* Where a coaxial cable does not have sufficient strength to be self-supporting, it shall be attached to a sup-

porting messenger cable that, together with the attachment fixtures or supports, shall be acceptable for the purpose and shall have sufficient strength to withstand the loads to which they may be subjected.

**(E) On Buildings.** Where attached to buildings, coaxial cables shall be securely fastened in such a manner that they will be separated from other conductors in accordance with 820.44(E)(1), (E)(2), and (E)(3).

**(1) Electric Light or Power.** The coaxial cable shall have a separation of at least 100 mm (4 in.) from electric light, power, Class 1, or non-power-limited fire alarm circuit conductors not in raceway or cable, or shall be permanently separated from conductors of the other system by a continuous and firmly fixed nonconductor in addition to the insulation on the wires.

**(2) Other Communications Systems.** Coaxial cable shall be installed so that there will be no unnecessary interference in the maintenance of the separate systems. In no case shall the conductors, cables, messenger strand, or equipment of one system cause abrasion to the conductors, cable, messenger strand, or equipment of any other system.

**(3) Lightning Conductors.** Where practicable, a separation of at least 1.8 m (6 ft) shall be maintained between any coaxial cable and lightning conductors.

Informational Note: For additional information regarding overhead (aerial) wires and cables, see ANSI C2-2007, *National Electric Safety Code*, Part 2, Safety Rules for Overhead Lines.

### 820.47 Underground Coaxial Cables Entering Buildings

Underground coaxial cables entering buildings shall comply with 820.47(A) and (B).

**(A) Underground Systems with Electric Light and Power Conductors.** Underground coaxial cables in a duct, pedestal, handhole enclosure, or manhole that contains electric light or power conductors or Class 1 circuits shall be in a section permanently separated from such conductors by means of a suitable barrier.

**(B) Direct-Buried Cables and Raceways.** Direct-buried coaxial cable shall be separated at least 300 mm (12 in.) from conductors of any light or power or Class 1 circuit.

*Exception No. 1: Where electric service conductors or coaxial cables are installed in raceways or have metal cable armor.*

*Exception No. 2: Where electric light or power branch-circuit or feeder conductors or Class 1 circuit conductors*

*are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables; or the coaxial cables have metal cable armor or are installed in a raceway.*

### 820.48 Unlisted Cables Entering Buildings

Unlisted outside plant coaxial cables shall be permitted to be installed in building spaces other than risers, ducts used for environmental air, plenums used for environmental air, and other spaces used for environmental air, where the length of the cable within the building, measured from its point of entrance, does not exceed 15 m (50 ft) and the cable enters the building from the outside and is terminated at a grounding block.

## III. Protection

### 820.93 Grounding of the Outer Conductive Shield of Coaxial Cables

Coaxial cables entering buildings or attached to buildings shall comply with 820.93(A) or (B). Where the outer conductive shield of a coaxial cable is grounded, no other protective devices shall be required. For purposes of this section, grounding located at mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, or at a mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, shall be considered to meet the requirements of this section.

Informational Note: Selecting a grounding location to achieve the shortest practicable bonding conductor or grounding electrode conductor helps limit potential differences between CATV and other metallic systems.

**(A) Entering Buildings.** In installations where the coaxial cable enters the building, the outer conductive shield shall be grounded in accordance with 820.100. The grounding shall be as close as practicable to the point of entrance.

**(B) Terminating Outside of the Building.** In installations where the coaxial cable is terminated outside of the building, the outer conductive shield shall be grounded in accordance with 820.100. The grounding shall be as close as practicable to the point of attachment or termination.

**(C) Location.** Where installed, a listed primary protector shall be applied on each community antenna and radio distribution (CATV) cable external to the premises. The listed primary protector shall be located as close as practicable to the entrance point of the cable on either side or integral to the ground block.

**(D) Hazardous (Classified) Locations.** Where a primary protector or equipment providing the primary protection

function is used, it shall not be located in any hazardous (classified) location as defined in 500.5 and 505.5 or in the vicinity of easily ignitable material.

*Exception:* As permitted in 501.150, 502.150, and 503.150.

## IV. Grounding Methods

### 820.100 Cable Bonding and Grounding

The shield of the coaxial cable shall be bonded or grounded as specified in 820.100(A) through (D).

*Exception:* For communications systems using coaxial cable confined within the premises and isolated from outside cable plant, the shield shall be permitted to be grounded by a connection to an equipment grounding conductor as described in 250.118. Connecting to an equipment grounding conductor through a grounded receptacle using a dedicated grounding conductor and permanently connected listed device shall be permitted. Use of a cord and plug for the connection to an equipment grounding conductor shall not be permitted.

#### (A) Bonding Conductor or Grounding Electrode Conductor.

**(1) Insulation.** The bonding conductor or grounding electrode conductor shall be listed and shall be permitted to be insulated, covered, or bare.

**(2) Material.** The bonding conductor or grounding electrode conductor shall be copper or other corrosion-resistant conductive material, stranded or solid.

**(3) Size.** The bonding conductor or grounding electrode conductor shall not be smaller than 14 AWG. It shall have a current-carrying capacity not less than the outer sheath of the coaxial cable. The bonding conductor or grounding electrode conductor shall not be required to exceed 6 AWG.

**(4) Length.** The grounding electrode conductor shall be as short as practicable. In one- and two-family dwellings, the bonding conductor or grounding electrode conductor shall be as short as practicable, not to exceed 6.0 m (20 ft) in length.

*Informational Note:* Similar bonding conductor or grounding electrode conductor length limitations applied at apartment buildings and commercial buildings help to reduce voltages that may be developed between the building's power and communications systems during lightning events.

*Exception:* In one- and two-family dwellings where it is not practicable to achieve an overall maximum bonding conductor or grounding electrode conductor length of 6.0 m (20 ft), a separate grounding electrode as specified in 250.52(A)(5),

(A)(6), or (A)(7) shall be used, the grounding electrode conductor shall be connected to the separate grounding electrode in accordance with 250.70, and the separate grounding electrode shall be connected to the power grounding electrode system in accordance with 820.100(D).

The 20-ft limitation on length results in a lower impedance, which in turn limits the potential difference between CATV systems and other systems during a lightning strike. Large potential differences between grounding conductors can result in increased damage if a lightning strike were to occur.

The informational note to 820.100(A)(4) provides guidance for the treatment of the cable and primary protector grounding conductor length at apartment and commercial buildings that is consistent with the 20-ft rule for one- and two-family dwellings. However, a specific length is not specified in the *Code*, because such a limitation may not be practical in some installations.

**(5) Run in Straight Line.** The bonding conductor or grounding electrode conductor shall be run in as straight a line as practicable.

**(6) Physical Protection.** Bonding conductors and grounding electrode conductors shall be protected where exposed to physical damage. Where the bonding conductor or grounding electrode conductor is installed in a metal raceway, both ends of the raceway shall be bonded to the contained conductor or to the same terminal or electrode to which the bonding conductor or grounding electrode conductor is connected.

**(B) Electrode.** The bonding conductor or grounding electrode conductor shall be connected in accordance with 820.100(B)(1), (B)(2), or (B)(3).

**(1) In Buildings or Structures with an Intersystem Bonding Termination.** If the building or structure served has an intersystem bonding termination as required by 250.94, the bonding conductor shall be connected to the intersystem bonding termination.

*Informational Note:* See Article 100 for the definition of *Intersystem Bonding Termination*.

**(2) In Buildings or Structures with Grounding Means.** If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on one of the following:

(1) The building or structure grounding electrode system as covered in 250.50

- (2) The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52

For more information on the use of a metal water piping system as a grounding electrode, see the commentary following 250.52(A)(1).

- (3) The power service accessible means external to enclosures as covered in 250.94, **Exception**
- (4) The **nonflexible** metallic power service raceway
- (5) The service equipment enclosure
- (6) The grounding electrode conductor or the grounding electrode conductor metal enclosure **of the power service**, or
- (7) The grounding **electrode** conductor or the grounding electrode of a building or structure disconnecting means that is connected to an electrode as covered in 250.32

A bonding device intended to provide a termination point for the grounding **electrode** conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on non-removable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is nonremovable.

For purposes of this section, the mobile home service equipment or the mobile home disconnecting means, as described in 820.93, shall be considered accessible.

**(3) In Buildings or Structures Without an Intersystem Bonding Termination or Grounding Means.** If the building or structure served has no intersystem bonding termination or grounding means, as described in 820.100(B)(2), the grounding electrode conductor shall be connected to either of the following:

- (1) To any one of the individual electrodes described in 250.52(A)(1), (A)(2), (A)(3), or **(A)(4)**
- (2) If the building or structure served has no intersystem bonding termination or grounding means, as described in 820.100(B)(2) or (B)(3)(1), to any one of the individual **grounding** electrodes described in 250.52(A)(5), (A)(7) and (A)(8).

**(C) Electrode Connection.** Connections to grounding electrodes shall comply with 250.70.

**(D) Bonding of Electrodes.** A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the community antenna television system's grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

*Exception: At mobile homes as covered in 820.106.*

Informational Note No. 1: See 250.60 for use of air terminals (lightning rods).

Informational Note No. 2: Bonding together of all separate electrodes limits potential differences between them and between their associated wiring systems.

Section 820.100(D) requires bonding of CATV and power grounding electrodes at the same building or structure. A common error made in grounding CATV systems is connecting the coaxial cable sheath to a rod-type grounding electrode driven by the CATV installer at a convenient location near the point of cable entry to the building, instead of bonding it to the electrical service grounding electrode system, service raceway, or other components that make up the grounding electrode system. A separate grounding electrode is permitted only if the building or structure has none of the grounding means described in 820.100(B)(1) or (B)(2), which is rare.

Section 250.94 requires that a bonding means with not less than three termination points that is accessible and external to the service equipment be provided for making the bonding and grounding connection for other systems. One of the following means is permitted for existing installations:

1. Exposed nonflexible metallic raceways
2. An exposed grounding electrode conductor
3. An approved means for the external connection of a conductor (A 6 AWG copper conductor with one end bonded to the service raceway or equipment with about 6 in. exposed is acceptable.)

Proper bonding of the CATV system coaxial cable sheath to the electrical power grounding electrode is needed to prevent potential fire and shock hazards. The earth cannot be used as an equipment grounding conductor or bonding conductor, because it does not have the required low-impedance path. (See 250.54.)

Both CATV systems and power systems are subject to current surges as a result of, for example, induced voltages from lightning in the vicinity of the usually extensive outside distribution systems. Surges also result from switching operations on power systems. If the grounded conductors and parts of the two systems are not bonded by a low-impedance path, such line surges can raise the potential difference between the two systems to many thousands of volts. This can result in arcing between the two systems — for example, wherever the coaxial cable jacket contacts a grounded part, such as a metal water pipe or metal structural member — inside the building.

If a person is the interface between the two systems and the bonding has not been done in accordance with the *Code*,

the high-voltage surge could result in electric shock. More common, however, is burnout of a television tuner, a part that is almost always an interface between the two systems. The tuner is connected to the power system ground through the grounded neutral of the power supply, even if the television set itself is not provided with an equipment grounding conductor.

Also see the commentary following 250.92(B) and 820.100(E).

**(E) Shield Protection Devices.** Grounding of a coaxial drop cable shield by means of a protective device that does not interrupt the grounding system within the premises shall be permitted.

Section 820.100(E) permits the use of a shield protection device that does not interrupt the grounding system within the premises. The electric utility supply, the CATV system, and the premises wiring are all grounded. When a ground fault occurs at the premises, the current tries to return to its source and follows the multiple paths through the different premises metal water piping systems or earth. Such ground faults can cause current on the CATV shield, whose primary function is to prevent RF leakage out of the cable. The fault current in the cable shield can cause the shield to burn open and also damage the cable insulation. A device that can safely conduct current at 60 Hz and block current at the higher frequencies can be connected between the cable shield and ground, thereby maintaining grounding integrity. An ordinary fuse, for example, would not be suitable.

### 820.103 Equipment Grounding

Unpowered equipment and enclosures or equipment powered by the coaxial cable shall be considered grounded where connected to the metallic cable shield.

### 820.106 Grounding and Bonding at Mobile Homes

**(A) Grounding.** Grounding shall comply with 820.106(A)(1) and (A)(2).

- (1) Where there is no mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the coaxial cable shield ground, or surge arrester ground, shall be connected to a grounding electrode conductor or grounding electrode in accordance with 820.100(B)(3).
- (2) Where there is no mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the coaxial cable shield ground, or surge arrester

ground, shall be connected to a grounding electrode in accordance with 820.100(B)(3).

**(B) Bonding.** The coaxial cable shield grounding terminal, surge arrester grounding terminal, or grounding electrode shall be connected to the metal frame or available grounding terminal of the mobile home with a copper conductor not smaller than 12 AWG under any of the following conditions:

- (1) Where there is no mobile home service equipment or disconnecting means as in 820.106(A)
- (2) Where the mobile home is supplied by cord and plug

## V. Installation Methods Within Buildings

### 820.110 Raceways for Coaxial Cables

**(A) Types of Raceways.** Coaxial cables shall be permitted to be installed in any raceway that complies with either (A)(1) or (A)(2).

**(1) Raceways Recognized in Chapter 3.** Coaxial cables shall be permitted to be installed in any raceway included in Chapter 3. The raceways shall be installed in accordance with the requirements of Chapter 3.

**(2) Other Permitted Raceways.** Coaxial cables shall be permitted to be installed in listed plenum communications raceway, listed riser communications raceway, or listed general-purpose communications raceway selected in accordance with the provisions of 820.113, and installed in accordance with 362.24 through 362.56, where the requirements applicable to electrical nonmetallic tubing apply.

**(B) Raceway Fill for Coaxial Cables.** The raceway fill requirements of Chapters 3 and 9 shall not apply to coaxial cables.

### 820.113 Installation of Coaxial Cables

Installation of coaxial cables shall comply with 820.113(A) through (K). Installation of raceways shall comply with 820.110.

**(A) Listing.** Coaxial cables installed in buildings shall be listed.

*Exception: Coaxial cables that comply with 820.48 shall not be required to be listed.*

**(B) Fabricated Ducts Used for Environmental Air.** The following cables shall be permitted in ducts as described in 300.22(B) if they are directly associated with the air distribution system:

- (1) Up to 1.22 m (4 ft) of Type CATVP cable
- (2) Types CATVP, CATVR, CATV, and CATVX cables installed in raceways that are installed in compliance with 300.22(B)

Informational Note: For information on fire protection of wiring installed in fabricated ducts see 4.3.4.1 and 4.3.11.3.3 in NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(C) Other Spaces Used For Environmental Air (Plenums).** The following cables shall be permitted in other spaces used for environmental air as described in 300.22(C):

- (1) Type CATVP cable
- (2) Type CATVP cable installed in plenum communications raceway
- (3) Type CATVP cable supported by open metallic cable trays or cable tray systems
- (4) Types CATVP, CATVR, CATV, and CATVX cables installed in raceways that are installed in compliance with 300.22(C)
- (5) Types CATVP, CATVR, CATV, and CATVX cables supported by solid bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air see 4.3.11.2, 4.3.11.4, and 4.3.11.5 of NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(D) Risers — Cables in Vertical Runs.** The following cables shall be permitted in vertical runs penetrating one or more floors and in vertical runs in a shaft:

- (1) Types CATVP and CATVR cables
- (2) Types CATVP and CATVR cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. Riser cable routing assembly

Informational Note: See 820.26 for firestop requirements for floor penetrations.

**(E) Risers — Cables in Metal Raceways.** The following cables shall be permitted in metal raceways in a riser having firestops at each floor:

- (1) Types CATVP, CATVR, CATV, and CATVX cables
- (2) Types CATVP, CATVR, CATV, and CATVX cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway

Informational Note: See 820.26 for firestop requirements for floor penetrations.

**(F) Risers — Cables in Fireproof Shafts.** The following cables shall be permitted to be installed in fireproof riser shafts with firestops at each floor:

- (1) Types CATVP, CATVR, CATV, and CATVX cables
- (2) Types CATVP, CATVR, and CATV cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

Informational Note: See 820.26 for firestop requirements for floor penetrations.

**(G) Risers — One- and Two-Family Dwellings.** The following cables shall be permitted in one- and two-family dwellings:

- (1) Types CATVP, CATVR, and CATV cables
- (2) Type CATVX cable less than 10 mm (0.375 in.) in diameter
- (3) Types CATVP, CATVR, and CATV cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

Informational Note: See 820.26 for firestop requirements for floor penetrations.

**(H) Cable Trays.** The following cables shall be permitted to be supported by cable trays:

- (1) Types CATVP, CATVR, and CATV cables
- (2) Types CATVP, CATVR, and CATV cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway

**(I) Distributing Frames and Cross-Connect Arrays.** The following cables shall be permitted to be installed in distributing frames and cross-connect arrays:

- (1) Types CATVP, CATVR, and CATV cables
- (2) Types CATVP, CATVR, and CATV cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

**(J) Other Building Locations.** The following cables and cable routing assemblies shall be permitted to be installed in building locations other than the locations covered in 820.113(B) through (I):

- (1) Types CATVP, CATVR, and CATV cables
- (2) A maximum of 3 m (10 ft) of exposed Type CATVX cable in nonconcealed spaces
- (3) Types CATVP, CATVR, and CATV cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly
- (4) Types CATVP, CATVR, CATV, and Type CATVX cables installed in a raceway of a type recognized in Chapter 3

**(K) One- and Two-Family and Multifamily Dwellings.** The following cables and cable routing assemblies shall be permitted to be installed in one- and two-family and multifamily dwellings in locations other than those locations covered in 820.113(B) through (I):

- (1) Types CATVP, CATVR, and CATV cables
- (2) Type CATVX cable less than 10 mm (0.375 in.) in diameter
- (3) Types CATVP, CATVR, and CATV cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly
- (4) Types CATVP, CATVR, CATV, and Type CATVX cables installed in a raceway of a type recognized in Chapter 3

### 820.133 Installation of Coaxial Cables and Equipment

Beyond the point of grounding, as defined in 820.93, the coaxial cable installation shall comply with 820.133(A) and (B).

Section 820.133 specifically includes separation from network-powered broadband communications circuits. Jackets of coaxial cable do not have sufficient construction specifications to permit them to be installed with electric light, power, Class 1, non-power-limited fire alarm circuits, and medium- and high-power network-powered broadband communications cable. Failure of the cable insulation due to a fault could lead to hazardous voltages being imposed on the Class 2 or Class 3 circuit conductors.

#### (A) Separation from Other Conductors.

##### (1) In Raceways, Routing Assemblies, Cable Trays, Boxes, and Enclosures.

(a) *Optical Fiber and Communications Cables.* Coaxial cables shall be permitted in the same raceway, cable tray, or

enclosure, or cable routing assembly with jacketed cables of any of the following:

- (1) Nonconductive and conductive optical fiber cables in compliance with Parts I and IV of Article 770
- (2) Communications circuits in compliance with Parts I and IV of Article 800
- (3) Low-power network-powered broadband communications circuits in compliance with Parts I and IV of Article 830

(b) *Other Circuits.* Coaxial cables shall be permitted in the same raceway, cable tray, or enclosure with jacketed cables of any of the following:

- (1) Class 2 and Class 3 remote-control, signaling, and power-limited circuits in compliance with Parts I and III of Article 725
- (2) Power-limited fire alarm systems in compliance with Parts I and III of Article 760

(c) *Electric Light, Power, Class 1, Non-Power-Limited Fire Alarm, and Medium-Power Network-Powered Broadband Communications Circuits.* Coaxial cable shall not be placed in any raceway, compartment, outlet box, junction box, or other enclosures with conductors of electric light, power, Class 1, non-power-limited fire alarm, or medium-power network-powered broadband communications circuits.

*Exception No. 1: Where all of the conductors of electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits are separated from all of the coaxial cables by a permanent barrier or listed divider.*

This exception recognizes the use of a listed field-installed divider to separate the communications circuits from the power circuits.

*Exception No. 2: Power circuit conductors in outlet boxes, junction boxes, or similar fittings or compartments where such conductors are introduced solely for power supply to the coaxial cable system distribution equipment. The power circuit conductors shall be routed within the enclosure to maintain a minimum 6-mm (0.25-in.) separation from coaxial cables.*

(2) **Other Applications.** Coaxial cable shall be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, non-power-limited fire alarm, or medium-

power network-powered broadband communications circuits.

*Exception No. 1: Where either (1) all of the conductors of electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits are in a raceway, or in metal-sheathed, metal-clad, nonmetallic-sheathed, Type AC or Type UF cables, or (2) all of the coaxial cables are encased in raceway.*

*Exception No. 2: Where the coaxial cables are permanently separated from the conductors of electric light, power, Class 1, non-power-limited fire alarm, and medium-power network-powered broadband communications circuits by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the wire.*

**(B) Support of Coaxial Cables.** Raceways shall be used for their intended purpose. Coaxial cables shall not be strapped, taped, or attached by any means to the exterior of any conduit or raceway as a means of support.

*Exception: Overhead (aerial) spans of coaxial cables shall be permitted to be attached to the exterior of a raceway-type mast intended for the attachment and support of such cables.*

### 820.154 Applications of Listed CATV Cables

Permitted and nonpermitted applications of listed coaxial cables shall be as indicated in Table 820.154(a). The permitted applications shall be subject to the installation requirements of 820.113. The substitutions for coaxial cables in Table 820.154(b) and illustrated in Figure 820.154 shall be permitted.

Table 820.154(a) provides a summary of applications for the coaxial cables covered in Article 820. Note that the permitted applications are a summary and are subject to the installation requirements of 820.113.

Informational Note: The substitute cables in Table 820.154(b) and Figure 820.154 are only coaxial-type cables.

**TABLE 820.154(a) Applications of Listed Coaxial Cables in Buildings**

Applications		Cable Type			
		CATVP	CATVR	CATV	CATVX
In fabricated ducts as described in 300.22(B)	In fabricated ducts as described in 300.22(B)	Y*	N	N	N
	In metal raceway that complies with 300.22(B)	Y*	Y*	Y*	Y*
In other spaces used for environmental air as described in 300.22(C)	In other spaces used for environmental air (plenums) as described in 300.22(C)	Y*	N	N	N
	In metal raceway that complies with 300.22(C)	Y*	Y*	Y*	Y*
	In plenum communications raceways	Y*	N	N	N
	Supported by open metal cable trays	Y*	N	N	N
	Supported by solid bottom metal cable trays with solid metal covers	Y*	Y*	Y*	Y*
In risers	In vertical runs	Y*	Y*	N	N
	In metal raceways	Y*	Y*	Y*	Y*
	In fireproof shafts	Y*	Y*	Y*	Y*
	In plenum communications raceways	Y*	Y*	N	N
	In riser communications raceways	Y*	Y*	N	N
	In riser cable routing assemblies	Y*	Y*	N	N
	In one- and two- family dwellings	Y*	Y*	Y*	Y*
Within buildings in other than air-handling spaces and risers	General	Y*	Y*	Y*	Y*
	In one- and two-family dwellings	Y*	Y*	Y*	Y*
	In multifamily dwellings	Y*	Y*	Y*	Y*

TABLE 820.154(a) Continued

Applications		Cable Type			
		CATVP	CATVR	CATV	CATVX
	In nonconcealed spaces	Y*	Y*	Y*	Y*
	Supported by cable trays	Y*	Y*	Y*	N
	In distributing frames and cross-connect arrays	Y*	Y*	Y*	N
	In any raceway recognized in Chapter 3	Y*	Y*	Y*	Y*
	In plenum communications raceways	Y*	Y*	Y*	N
	In riser communications raceways	Y*	Y*	Y*	N
	In general-purpose communications raceways	Y*	Y*	Y*	N
	In riser cable routing assemblies	Y*	Y*	Y*	N
	In general-purpose cable routing assemblies	Y*	Y*	Y*	N

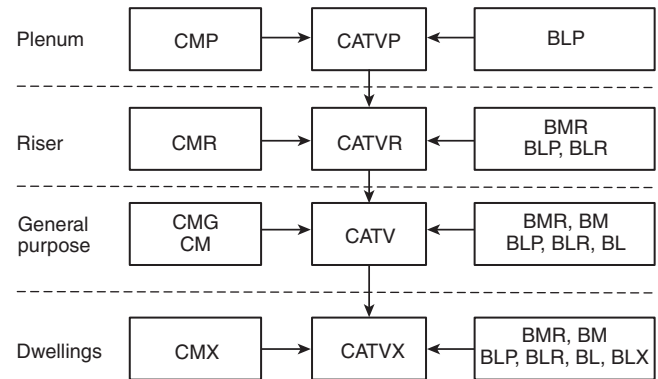

Note: An “N” in the table indicates that the cable type is not permitted to be installed in the application. A “Y\*” indicates that the cable is permitted to be installed in the application, subject to the limitations described in 820.113.

Informational Note 1: Part V of Article 820 covers installation methods within buildings. This table covers the applications of listed coaxial cables in buildings. The definition of point of entrance is in 820.2. Coaxial entrance cables that have not emerged from the rigid metal conduit or intermediate metal conduit are not considered to be in the building.

Informational Note No. 2: For information on the restrictions to the installation of communications cables in fabricated ducts see 820.113(B).

TABLE 820.154(b) Coaxial Cable Uses and Permitted Substitutions

Cable Type	Permitted Substitutions
CATVP	CMP, BLP
CATVR	CATVP, CMP, CMR, BMR, BLP, BLR
CATV	CATVP, CMP, CATVR, CMR, CMG, CM, BMR, BM, BLP, BLR, BL
CATVX	CATVP, CMP, CATVR, CMR, CATV, CMG, CM, BMR, BM, BLP, BLR, BL, BLX

[A] → [B] Coaxial cable A shall be permitted to be used in place of coaxial cable B.

Type BL—Network-powered broadband communications low-power cable

Type BM—Network-powered broadband communications medium-power cable

Type CATV—Community antenna television cables

Type CM—Communications cables

Figure 820.154 Cable Substitution Hierarchy.

## VI. Listing Requirements

### 820.179 Coaxial Cables

Cables shall be listed in accordance with 820.179(A) through (D) and marked in accordance with Table 820.179. The cable voltage rating shall not be marked on the cable.

Informational Note: Voltage markings on cables could be misinterpreted to suggest that the cables may be suitable for Class 1, electric light, and power applications.

*Exception: Voltage markings shall be permitted where the cable has multiple listings and voltage marking is required for one or more of the listings.*

**(A) Type CATVP.** Type CATVP community antenna television plenum coaxial cables shall be listed as being suitable for use in ducts, plenums, and other spaces used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

**TABLE 820.179 Coaxial Cable Markings**

Cable Marking	Type
CATVP	CATV plenum cable
CATVR	CATV riser cable
CATV	CATV cable
CATVX	CATV cable, limited use

Informational Note: One method of defining a cable that is low smoke-producing cable and fire-resistant cable is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

See the commentary following the informational note to 725.179(A).

**(B) Type CATVR.** Type CATVR community antenna television riser coaxial cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2002, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

See the commentary following the informational note to 725.179(B).

**(C) Type CATV.** Type CATV community antenna television coaxial cables shall be listed as being suitable for general-purpose CATV use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining *resistant to the spread of fire* is that the cables do not spread fire to the top of the tray in the “UL Flame Exposure, Vertical Tray Flame Test” in UL 1685-2000, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining *resistant to the spread of fire* is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA “Vertical Flame Test — Cables in Cable Trays,” as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

See the commentary following the informational note to 725.179(C).

**(D) Type CATVX.** Type CATVX limited-use community antenna television coaxial cables shall be listed as being suitable for use in dwellings and for use in raceway and shall also be listed as being resistant to flame spread.

Informational Note: One method of determining that cable is resistant to flame spread is by testing the cable to the VW-1 (vertical-wire) flame test in ANSI/UL 1581-2001, *Reference Standard for Electrical Wires, Cables and Flexible Cords*.

See the commentary following the informational note to 725.179(D).

**Informational Note:** The general term *grounding conductor* as previously used in this article is replaced by either the term *bonding conductor* or the term *grounding electrode conductor* (GEC), where applicable, to more accurately reflect the application and function of the conductor.

This informational note explains the revision of the term *grounding conductor* to *bonding conductor* and *grounding electrode conductor* throughout Article 830.

This informational note and Figures 800(a) and 800(b) explain how the new, more precise terms (*bonding conductor* and *grounding electrode conductor*) are implemented in the requirements that formerly used the term *grounding conductor*. These terms are new to Article 830 but have had long-standing use in other *Code* articles. See Article 100 for their definitions. The figures are located in Article 800 but the concepts depicted are applicable in Article 830.

## I. General

### 830.1 Scope

This article covers network-powered broadband communications systems that provide any combination of voice, audio, video, data, and interactive services through a network interface unit.

**Informational Note No. 1:** A typical basic system configuration includes a cable supplying power and broadband signal to a network interface unit that converts the broadband signal to the component signals. Typical cables are coaxial cable with both broadband signal and power on the center conductor, composite metallic cable with a coaxial member for the broadband signal and a twisted pair for power, and composite optical fiber cable with a pair of conductors for power. Larger systems may also include network components such as amplifiers that require network power.

**Informational Note No. 2:** See 90.2(B)(4) for installations of broadband communications systems that are not covered.

Article 830 covers network-powered broadband communications circuits, which provide a wide array of subscriber services, including voice, data (such as Internet access), interactive services, and television signals.

Article 830 contains requirements for wiring both the inside and the outside of buildings. Other articles cover the wiring derived from the network interface unit (NIU) into the premises. For example, Article 725 covers wiring of Class 2 and Class 3 circuits, Article 760 covers wiring of fire alarm systems, Article 770 covers the installation of optical fiber cable, Article 800 covers communications (telephone) wiring, and Article 820 covers coaxial cable installations for television signals. The major difference between Article 820 and Article 830 is the voltage present on the circuit conductors. Article 820 systems are limited to 60 volts, but Article 830 systems are permitted to have ratings as high as 150 volts. Higher voltages allow systems to power more sophisticated electronics and to provide a wider variety of services.

### 830.2 Definitions

See Article 100. For purposes of this article, the following additional definitions apply.

**Abandoned Network-Powered Broadband Communications Cable.** Installed network-powered broadband communications cable that is not terminated at equipment other than a connector and not identified for future use with a tag.

The definition of *abandoned network-powered broadband communications cable* applies to 830.25, which requires the removal of accessible abandoned broadband communications cable. Abandoned cable increases fire loading unnecessarily and, where installed in plenums, can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 770, 800, and 820.

Informational Note: See Article 100 for a definition of *Equipment*.

**Block.** A square or portion of a city, town, or village enclosed by streets, including the alleys so enclosed but not any street.

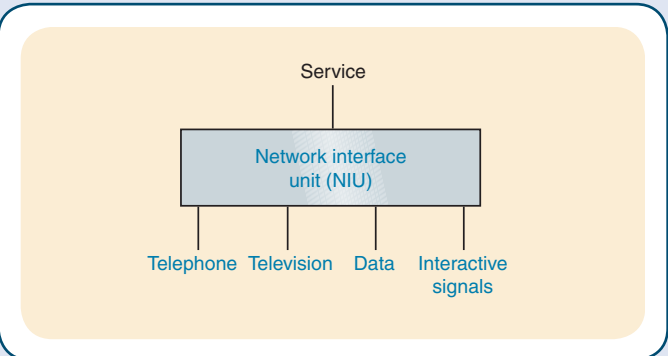

**Exposed (to Accidental Contact).** A circuit in such a position that, in case of failure of supports or insulation, contact with another circuit may result.

Informational Note: See Article 100 for two other definitions of *Exposed*.

**Fault Protection Device.** An electronic device that is intended for the protection of personnel and functions under fault conditions, such as network-powered broadband communications cable short or open circuit, to limit the current or voltage, or both, for a low-power network-powered broadband communications circuit and provide acceptable protection from electric shock.

**Network Interface Unit (NIU).** A device that converts a broadband signal into component voice, audio, video, data, and interactive services signals. The NIU provides isolation between the network power and the premises signal circuits. The NIU may also contain primary and secondary protectors.

Exhibit 830.1 illustrates a network interface unit with derived circuits.

**EXHIBIT 830.1** A network interface unit (NIU) diagram showing derived circuits.

**Network-Powered Broadband Communications Circuit.** The circuit extending from the communications utility's serving terminal or tap up to and including the NIU.

Informational Note: A typical single-family network-powered communications circuit consists of a communications drop or communications service cable and an NIU and includes the communications utility's serving terminal or tap where it is not under the exclusive control of the communications utility.

**Point of Entrance.** The point within a building at which the cable emerges from an external wall, from a concrete floor slab, or from a rigid metal conduit (Type RMC) or an intermediate metal conduit (Type IMC) connected by a bonding conductor or grounding electrode conductor in accordance with 830.100(B).

### 830.3 Other Articles

Circuits and equipment shall comply with 830.3(A) through (F).

**(A) Hazardous (Classified) Locations.** Network-powered broadband communications circuits and equipment installed in a location that is classified in accordance with 500.5 and 505.5 shall comply with the applicable requirements of Chapter 5.

•

**(B) Equipment in Other Space Used for Environmental Air.** Section 300.22(C) shall apply.

**(C) Output Circuits.** As appropriate for the services provided, the output circuits derived from the network interface unit shall comply with the requirements of the following:

- (1) Installations of communications circuits — Article 800
- (2) Installations of community antenna television and radio distribution circuits — Article 820

*Exception: 830.90(B)(3) shall apply where protection is provided in the output of the NIU.*

- (3) Installations of optical fiber cables — Article 770
- (4) Installations of Class 2 and Class 3 circuits — Article 725
- (5) Installations of power-limited fire alarm circuits — Article 760

**(D) Installation and Use.** The requirements of 110.3(B) shall apply.

**(E) Protection Against Physical Damage.** The requirements of 300.4 shall apply.

**(F) Cable Routing Assemblies.** The definition in 770.2, the applications in 770.154, and the installation rules in 770.113 shall apply to Article 830.

### 830.15 Power Limitations

Network-powered broadband communications systems shall be classified as having low- or medium-power sources as specified in 830.15(1) or (2).

- (1) Sources shall be classified as defined in Table 830.15.
- (2) Direct-current power sources exceeding 150 volts to ground, but no more than 200 volts to ground, with the current to ground limited to 10 mA dc, that meet the current and power limitation for medium-power sources in Table 830.15 shall be classified as medium-power sources.

**Informational Note:** One way to determine compliance with 830.15(2) is listed information technology equipment intended to supply power via a **communications** network that complies with the requirements for RFT-V circuits as defined in UL 60950-21-2003, *Standard for Safety for Information Technology Equipment — Safety — Part 21: Remote Power Feeding*.

The *Code* recognizes the installation of only those network-powered broadband systems that operate within the voltage, current, and power parameters specified in Table 830.15 or a

**TABLE 830.15 Limitations for Network-Powered Broadband Communications Systems**

Network Power Source	Low	Medium
Circuit voltage, $V_{\max}$ (volts) <sup>1</sup>	0–100	0–150
Power limitation, $VA_{\max}$ (volt-amperes) <sup>1</sup>	250	250
Current limitation, $I_{\max}$ (amperes) <sup>1</sup>	$1000/V_{\max}$	$1000/V_{\max}$
Maximum power rating (volt-amperes)	100	100
Maximum voltage rating (volts)	100	150
Maximum overcurrent protection (amperes) <sup>2</sup>	$100/V_{\max}$	NA

<sup>1</sup> $V_{\max}$ ,  $I_{\max}$ , and  $VA_{\max}$  are determined with the current-limiting impedance in the circuit (not bypassed) as follows:

$V_{\max}$  — Maximum system voltage regardless of load with rated input applied.

$I_{\max}$  — Maximum system current under any noncapacitive load, including short circuit, and with overcurrent protection bypassed if used.  $I_{\max}$  limits apply after 1 minute of operation.

$VA_{\max}$  — Maximum volt-ampere output after 1 minute of operation regardless of load and overcurrent protection bypassed if used.

<sup>2</sup>Overcurrent protection is not required where the current-limiting device provides equivalent current limitation and the current-limiting device does not reset until power or the load is removed.

direct-current system operating at not more than 200 volts to ground with a current to ground not more than 10 mA. These dc systems are considered to be medium-power broadband sources, provided they meet the current and power limitations for medium-power systems specified in Table 830.15.

### 830.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of network-powered broadband communications cables that prevents removal of panels, including suspended ceiling panels.

An excess accumulation of wires and cables can limit access to equipment by preventing the removal of access panels. (See Exhibit 830.2.)

### 830.24 Mechanical Execution of Work

Network-powered broadband communications circuits and equipment shall be installed in a neat and workmanlike manner. Cables installed exposed on the surface of ceilings and sidewalls shall be supported by the building structure in such a manner that the cable will not be damaged by normal building use. Such cables shall be secured by hardware including straps, staples, cable ties, hangers, or similar fittings designed and installed so as not to damage the cable. The installation shall also conform to 300.4(D) and 300.11.

**EXHIBIT 830.2** *Incorrect installation of conductors and cables (upper diagram), which can prevent access to equipment or cables. Correct method is shown in the lower diagram.*

Section 830.24 provides definitive requirements for workmanship. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable must be carefully evaluated to ensure that activities and processes within the building do not damage the cable. Although this requirement does not contain specific supporting and securing intervals, it does reference 300.11 as a general rule on securing equipment and cables, and 300.4(D) for protection of cables installed parallel to framing methods.

Informational Note No. 1: Accepted industry practices are described in ANSI/NECA/BICSI 568-2006, *Standard for Installing Commercial Building Telecommunications Cabling*; ANSI/TIA/EIA-568-B.1-2004 — Part 1 General Requirements Commercial Building Telecommunications Cabling Standard; ANSI/TIA-569-B-2004, *Commercial Building Standard for Telecommunications Pathways and Spaces*; ANSI/TIA-570-B-2009, *Residential Telecommunications Infrastructure*; and other ANSI-approved installation standards.

Informational Note No. 2: See NFPA 90A-2009, *Standard for Installation of Air-Conditioning and Ventilating Systems*, for discrete combustible components installed in accordance with 300.22(B) and (C).

### 830.25 Abandoned Cables

The accessible portion of abandoned network-powered broadband cables shall be removed. Where cables are identi-

fied for future use with a tag, the tag shall be of sufficient durability to withstand the environment involved.

This section requires the removal of abandoned network-powered broadband communications cable that is accessible. See Article 100 for the definition of *accessible*. Abandoned cable increases fire loading unnecessarily and, where installed in plenums, can affect airflow. Similar requirements can be found in Articles 640, 645, 725, 760, 770, 800, and 820. (Also see the definition of *abandoned network-powered broadband communications cable* in 830.2.)

### 830.26 Spread of Fire or Products of Combustion

Installations of network-powered broadband cables in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations of network-powered broadband cables through fire-resistant-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

Informational Note: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made. Building codes also contain restrictions on membrane penetrations on opposite sides of a fire resistance-rated wall assembly. An example is the 600-mm (24-in.) minimum horizontal separation that usually applies between boxes installed on opposite sides of the wall. Assistance in complying with 830.26 can be found in building codes, fire resistance directories, and product listings.

## II. Cables Outside and Entering Buildings

### 830.40 Entrance Cables

Network-powered broadband communications cables located outside and entering buildings shall comply with 830.40(A) and (B).

**(A) Medium-Power Circuits.** Medium-power network-powered broadband communications circuits located outside and entering buildings shall be installed using Type BMU, Type BM, or Type BMR network-powered broadband communications medium-power cables.

**(B) Low-Power Circuits.** Low-power network-powered broadband communications circuits located outside and entering buildings shall be installed using Type BLU or Type BLX low-power network-powered broadband communications cables. Cables shown in Table 830.154(b) shall be permitted to substitute.

*Exception: Outdoor community antenna television and radio distribution system coaxial cables installed prior to January 1, 2000, and installed in accordance with Article 820, shall be permitted for low-power-type, network-powered broadband communications circuits.*

### 830.44 Overhead (Aerial) Cables

Overhead (aerial) network-powered broadband communications cables shall comply with 830.44(A) through (G).

Informational Note: For additional information regarding overhead (aerial) wires and cables, see ANSI C2-2007, *National Electrical Safety Code*, Part 2, Safety Rules for Overhead Lines.

Network-powered broadband communications systems may contain sufficient energy to pose injurious or fatal electric shock hazards. For that reason, they are subject to requirements similar to those for other high-powered circuits.

Section 830.44 requires that conductor spans be of sufficient size and strength to maintain clearances and avoid possible contact with light or power conductors. Splices and joints must be made with approved connectors or other means that provide sufficient mechanical strength so that conductors are not weakened appreciably, which could cause them to break and come into contact with higher-voltage conductors.

**(A) On Poles and In-Span.** Where network-powered broadband communications cables and electric light or power conductors are supported by the same pole or are run parallel to each other in-span, the conditions described in 830.44(A)(1) through (A)(4) shall be met.

**(1) Relative Location.** Where practicable, the network-powered broadband communications cables shall be located below the electric light or power conductors.

**(2) Attachment to Cross-Arms.** Network-powered broadband communications cables shall not be attached to a cross-arm that carries electric light or power conductors.

**(3) Climbing Space.** The climbing space through network-powered broadband communications wires and cables shall comply with the requirements of 225.14(D).

**(4) Clearance.** Lead-in or overhead (aerial)-drop network-powered broadband communications cables from a pole or other support, including the point of initial attachment to a building or structure, shall be kept away from electric light, power, Class 1, or non-power-limited fire alarm circuit conductors so as to avoid the possibility of accidental contact.

*Exception: Where proximity to electric light, power, Class 1, or non-power-limited fire alarm circuit conductors cannot be avoided, the installation shall provide clearances of not less than 300 mm (12 in.) from electric light, power, Class 1, or non-power-limited fire alarm circuit conductors. The clearance requirement shall apply to all points along the drop, and it shall increase to 1.02 m (40 in.) at the pole.*

**(B) Above Roofs.** Network-powered broadband communications cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

*Exception No. 1: Auxiliary buildings such as garages and the like.*

*Exception No. 2: A reduction in clearance above only the overhanging portion of the roof to not less than 450 mm (18 in.) shall be permitted if (1) not more than 1.2 m (4 ft) of the broadband communications drop cables pass above the roof overhang, and (2) they are terminated at a through-the-roof raceway or support.*

*Exception No. 3: Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.*

**(C) Clearance from Ground.** Overhead (aerial) spans of network-powered broadband communications cables shall conform to not less than the following:

- (1) 2.9 m (9.5 ft) — above finished grade, sidewalks, or from any platform or projection from which they might be reached and accessible to pedestrians only
- (2) 3.5 m (11.5 ft) — over residential property and driveways, and those commercial areas not subject to truck traffic
- (3) 4.7 m (15.5 ft) — over public streets, alleys, roads, parking areas subject to truck traffic, driveways on other than residential property, and other land traversed by vehicles such as cultivated, grazing, forest, and orchard

Informational Note: These clearances have been specifically chosen to correlate with ANSI C2-2007, *National Electrical Safety Code*, Table 232-1, which provides for clearances of wires, conductors, and cables above ground and roadways, rather than using the clearances referenced in 225.18. Because Article 800 and Article 820 have had no required clearances, the communications industry has used the clearances from the NESC for their installed cable plant.

**(D) Over Pools.** Clearance of network-powered broadband communications cable in any direction from the water level, edge of pool, base of diving platform, or anchored raft shall comply with those clearances in 680.8.

**(E) Final Spans.** Final spans of network-powered broadband communications cables without an outer jacket shall be

permitted to be attached to the building, but they shall be kept not less than 900 mm (3 ft) from windows that are designed to be opened, doors, porches, balconies, ladders, stairs, fire escapes, or similar locations.

*Exception: Conductors run above the top level of a window shall be permitted to be less than the 900-mm (3-ft) requirement above.*

Overhead (aerial) network-powered broadband communications cables shall not be installed beneath openings through which materials might be moved, such as openings in farm and commercial buildings, and shall not be installed where they obstruct entrance to these building openings.

**(F) Between Buildings.** Network-powered broadband communications cables extending between buildings or structures, and also the supports or attachment fixtures, shall be identified as suitable for outdoor aerial applications and shall have sufficient strength to withstand the loads to which they may be subjected.

Wind and ice loads must be considered because they can damage cables and attachment points.

*Exception: Where a network-powered broadband communications cable does not have sufficient strength to be self-supporting, it shall be attached to a supporting messenger cable that, together with the attachment fixtures or supports, shall be acceptable for the purpose and shall have sufficient strength to withstand the loads to which they may be subjected.*

**(G) On Buildings.** Where attached to buildings, network-powered broadband communications cables shall be securely fastened in such a manner that they are separated from other conductors in accordance with 830.44(I)(1) through (I)(4).

**(1) Electric Light or Power.** The network-powered broadband communications cable shall have a separation of at least 100 mm (4 in.) from electric light, power, Class 1, or non-power-limited fire alarm circuit conductors not in raceway or cable, or be permanently separated from conductors of the other system by a continuous and firmly fixed non-conductor in addition to the insulation on the wires.

**(2) Other Communications Systems.** Network-powered broadband communications cables shall be installed so that there will be no unnecessary interference in the maintenance of the separate systems. In no case shall the conductors, ca-

bles, messenger strand, or equipment of one system cause abrasion to the conductors, cables, messenger strand, or equipment of any other system.

**(3) Lightning Conductors.** Where practicable, a separation of at least 1.8 m (6 ft) shall be maintained between any network-powered broadband communications cable and lightning conductors.

**(4) Protection from Damage.** Network-powered broadband communications cables attached to buildings or structures and located within 2.5 m (8 ft) of finished grade shall be protected by enclosures, raceways, or other approved means.

*Exception: A low-power network-powered broadband communications circuit that is equipped with a listed fault protection device, appropriate to the network-powered broadband communications cable used, and located on the network side of the network-powered broadband communications cable being protected.*

### 830.47 Underground Network-Powered Broadband Communications Cables Entering Buildings

Underground network-powered broadband communications cables entering buildings shall comply with 830.47(A) through (D).

**(A) Underground Systems with Electric Light and Power Conductors.** Underground network-powered broadband communications cables in a duct, pedestal, handhole enclosure, or manhole that contains electric light, power conductors, non-power-limited fire alarm circuit conductors, or Class 1 circuits shall be in a section permanently separated from such conductors by means of a suitable barrier.

**(B) Direct-Buried Cables and Raceways.** Direct-buried network-powered broadband communications cables shall be separated by at least 300 mm (12 in.) from conductors of any light, power, non-power-limited fire alarm circuit conductors or Class 1 circuit.

*Exception No. 1: Where electric service conductors or network-powered broadband communications cables are installed in raceways or have metal cable armor.*

*Exception No. 2: Where electric light or power branch-circuit or feeder conductors, non-power-limited fire alarm circuit conductors, or Class 1 circuit conductors are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables; or the network-powered*

broadband communications cables have metal cable armor or are installed in a raceway.

**(C) Mechanical Protection.** Direct-buried cable, conduit, or other raceways shall be installed to meet the minimum cover requirements of Table 830.47. In addition, direct-buried cables emerging from the ground shall be protected by enclosures, raceways, or other approved means extending from the minimum cover distance required by Table 830.47 below grade to a point at least 2.5 m (8 ft) above finished grade. In no case shall the protection be required to exceed 450 mm (18 in.) below finished grade. Type BMU and BLU direct-buried cables emerging from the ground shall be installed in rigid metal conduit, intermediate metal conduit, rigid nonmetallic conduit, or other approved means extending from the minimum cover distance required by Table 830.47 below grade to the point of entrance.

*Exception: A low-power network-powered broadband communications circuit that is equipped with a listed fault protection device, appropriate to the network-powered broadband communications cable used, and located on the*

*network side of the network-powered broadband communications cable being protected.*

**(D) Pools.** Cables located under the pool or within the area extending 1.5 m (5 ft) horizontally from the inside wall of the pool shall meet those clearances and requirements specified in 680.10.

### III. Protection

#### 830.90 Primary Electrical Protection

**(A) Application.** Primary electrical protection shall be provided on all network-powered broadband communications conductors that are neither grounded nor interrupted and are run partly or entirely in aerial cable not confined within a block. Also, primary electrical protection shall be provided on all aerial or underground network-powered broadband communications conductors that are neither grounded nor interrupted and are located within the block containing the building served so as to be exposed to lightning or accidental contact with electric light or power conductors operating at over 300 volts to ground.

**TABLE 830.47 Network-Powered Broadband Communications Systems Minimum Cover Requirements (Cover is the shortest distance measured between a point on the top surface of any direct-buried cable, conduit, or other raceway and the top surface of finished grade, concrete, or similar cover.)**

Location of Wiring Method or Circuit	Direct Burial Cables		Rigid Metal Conduit or Intermediate Metal Conduit		Nonmetallic Raceways Listed for Direct Burial; Without Concrete Encasement or Other Approved Raceways	
	mm	in.	mm	in.	mm	in.
All locations not specified below	450	18	150	6	300	12
In trench below 50-mm (2-in.) thick concrete or equivalent	300	12	150	6	150	6
Under a building (in raceway only)	0	0	0	0	0	0
Under minimum of 100-mm (4-in.) thick concrete exterior slab with no vehicular traffic and the slab extending not less than 150 mm (6 in.) beyond the underground installation	300	12	100	4	100	4
One- and two-family dwelling driveways and outdoor parking areas and used only for dwelling-related purposes	300	12	300	12	300	12

**Notes:**

1. Raceways approved for burial only where concrete encased shall require a concrete envelope not less than 50 mm (2 in.) thick.
2. Lesser depths shall be permitted where cables rise for terminations or splices or where access is otherwise required.
3. Where solid rock is encountered, all wiring shall be installed in metal or nonmetallic raceway permitted for direct burial. The raceways shall be covered by a minimum of 50 mm (2 in.) of concrete extending down to rock.
4. Low-power network-powered broadband communications circuits using directly buried community antenna television and radio distribution system coaxial cables that were installed outside and entering buildings prior to January 1, 2000, in accordance with Article 820 shall be permitted where buried to a minimum depth of 300 mm (12 in.).

*Exception: Where electrical protection is provided on the derived circuit(s) (output side of the NIU) in accordance with 830.90(B)(3).*

Informational Note No. 1: On network-powered broadband communications conductors not exposed to lightning or accidental contact with power conductors, providing primary electrical protection in accordance with this article helps protect against other hazards, such as ground potential rise caused by power fault currents, and above-normal voltages induced by fault currents on power circuits in proximity to the network-powered broadband communications conductors.

Informational Note No. 2: Network-powered broadband communications circuits are considered to have a lightning exposure unless one or more of the following conditions exist:

- (1) Circuits in large metropolitan areas where buildings are close together and sufficiently high to intercept lightning.
- (2) Areas having an average of five or fewer thunderstorm days each year and earth resistivity of less than 100 ohm-meters. Such areas are found along the Pacific coast.

Utility companies may provide primary protectors if conductors are exposed to lightning. Generally, cable is not considered to be exposed to lightning unless one or both of the conditions in Informational Note No. 2 exist. A primary protector is required at each end of a communications circuit where lightning exposure exists, unless protection is provided on the output side of the network interface unit (NIU).

**(1) Fuseless Primary Protectors.** Fuseless-type primary protectors shall be permitted where power fault currents on all protected conductors in the cable are safely limited to a value no greater than the current-carrying capacity of the primary protector and of the primary protector grounding conductor.

**(2) Fused Primary Protectors.** Where the requirements listed in 830.90(A)(1) are not met, fused-type primary protectors shall be used. Fused-type primary protectors shall consist of an arrester connected between each conductor to be protected and ground, a fuse in series with each conductor to be protected, and an appropriate mounting arrangement. Fused primary protector terminals shall be marked to indicate line, instrument, and ground, as applicable.

**(B) Location.** The location of the primary protector, where required, shall comply with (B)(1), (B)(2), or (B)(3):

- (1) A listed primary protector shall be applied on each network-powered broadband communications cable external to and on the network side of the network interface unit.

- (2) The primary protector function shall be an integral part of and contained in the network interface unit. The network interface unit shall be listed as being suitable for application with network-powered broadband communications systems and shall have an external marking indicating that it contains primary electrical protection.
- (3) The primary protector(s) shall be provided on the derived circuit(s) (output side of the NIU), and the combination of the NIU and the protector(s) shall be listed as being suitable for application with network-powered broadband communications systems.

A primary protector, whether provided integrally or external to the network interface unit, shall be located as close as practicable to the point of entrance.

For purposes of this section, a network interface unit and any externally provided primary protectors located at mobile home service equipment located in sight from and not more than 9.0 m (30 ft) from the exterior wall of the mobile home it serves, or at a mobile home disconnecting means grounded in accordance with 250.32 and located in sight from and not more than 9.0 m (30 ft) from the exterior wall of the mobile home it serves, shall be considered to meet the requirements of this section.

Informational Note: Selecting a network interface unit and primary protector location to achieve the shortest practicable primary protector bonding conductor or grounding electrode conductor helps limit potential differences between communications circuits and other metallic systems.

**(C) Hazardous (Classified) Locations.** The primary protector or equipment providing the primary protection function shall not be located in any hazardous (classified) location as defined in 500.5 and 505.5 or in the vicinity of easily ignitable material.

*Exception: As permitted in 501.150, 502.150, and 503.150.*

### 830.93 Grounding or Interruption of Metallic Members of Network-Powered Broadband Communications Cables

Network-powered communications cables entering buildings or attaching to buildings shall comply with 830.93(A) or (B).

For purposes of this section, grounding located at mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, or at a mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, shall be considered to meet the requirements of this section.

Informational Note: Selecting a grounding location to achieve the shortest practicable bonding conductor or grounding electrode conductor helps limit potential differ-

ences between the network-powered broadband communications circuits and other metallic systems.

**(A) Entering Buildings.** In installations where the network-powered communications cable enters the building, the shield shall be grounded in accordance with 830.100 and metallic members of the cable not used for communications or powering shall be grounded in accordance with 830.100, or interrupted by an insulating joint or equivalent device. The grounding or interruption shall be as close as practicable to the point of entrance.

**(B) Terminating Outside of the Building.** In installations where the network-powered communications cable is terminated outside of the building, the shield shall be grounded in accordance with 830.100, and metallic members of the cable not used for communications or powering shall be grounded in accordance with 830.100 or interrupted by an insulating joint or equivalent device. The grounding or interruption shall be as close as practicable to the point of attachment of the NIU.

Informational Note: See 830.2 for the definition of *Point of Entrance*.

## IV. Grounding Methods

### 830.100 Cable, Network Interface Unit, and Primary Protector Bonding and Grounding

Network interface units containing protectors, NIUs with metallic enclosures, primary protectors, and the metallic members of the network-powered broadband communications cable that are intended to be bonded or grounded shall be connected as specified in 830.100(A) through (D).

#### (A) Bonding Conductor or Grounding Electrode Conductor.

**(1) Insulation.** The bonding conductor or grounding electrode conductor shall be listed and shall be permitted to be insulated, covered, or bare.

**(2) Material.** The bonding conductor or grounding electrode conductor shall be copper or other corrosion-resistant conductive material, stranded or solid.

**(3) Size.** The bonding conductor or grounding electrode conductor shall not be smaller than 14 AWG and shall have a current-carrying capacity not less than that of the grounded metallic member(s) and protected conductor(s) of the network-powered broadband communications cable. The bonding conductor or grounding electrode conductor shall not be required to exceed 6 AWG.

**(4) Length.** The bonding conductor and grounding electrode conductor shall be as short as practicable. In one- and

two-family dwellings, the bonding conductor and grounding electrode conductor shall be as short as practicable, not to exceed 6.0 m (20 ft) in length.

Informational Note: Similar bonding conductor or grounding electrode conductor length limitations applied at apartment buildings and commercial buildings help to reduce voltages that may be developed between the building's power and communications systems during lightning events.

*Exception: In one- and two-family dwellings where it is not practicable to achieve an overall maximum bonding conductor or grounding electrode conductor length of 6.0 m (20 ft), a separate communications ground rod meeting the minimum dimensional criteria of 830.100(B)(3)(2) shall be driven, and the grounding electrode conductor shall be connected to the communications ground rod in accordance with 830.100(C). The communications ground rod shall be bonded to the power grounding electrode system in accordance with 830.100(D).*

The limitation on length will result in a lower impedance, which will limit the potential difference between network-powered broadband communications systems and other systems during a lightning strike. Large potential differences between grounding conductors can result in increased damage if a lightning strike were to occur.

The informational note to 830.100(A)(4) provides guidance for the treatment of the cable and primary protector grounding conductor length at apartment and commercial buildings that is consistent with the 20-ft rule for one- and two-family dwellings. However, a specific length is not specified in the *Code*, because such a limitation may not be practical in some installations.

**(5) Run in Straight Line.** The bonding conductor or grounding electrode conductor shall be run in as straight a line as practicable.

**(6) Physical Protection.** Bonding conductors and grounding electrode conductors shall be protected where exposed to physical damage. Where the bonding conductor or grounding electrode conductor is installed in a metal raceway, both ends of the raceway shall be bonded to the contained conductor or to the same terminal or electrode to which the bonding conductor or grounding electrode conductor is connected.

**(B) Electrode.** The bonding conductor or grounding electrode conductor shall be connected in accordance with 830.100(B)(1), (B)(2), or (B)(3).

**(1) In Buildings or Structures with an Intersystem Bonding Termination.** If the building or structure served

has an intersystem bonding termination as required by 250.94, the bonding conductor shall be connected to the intersystem bonding termination.

**Informational Note:** See Article 100 for the definition of *Intersystem Bonding Termination*.

**(2) In Buildings or Structures with Grounding Means.** If the building or structure served has no intersystem bonding termination, the bonding conductor or grounding electrode conductor shall be connected to the nearest accessible location on one of the following:

- (1) The building or structure grounding electrode system as covered in 250.50
- (2) The grounded interior metal water piping system, within 1.5 m (5 ft) from its point of entrance to the building, as covered in 250.52

For more information on the use of a metal water piping system as a grounding electrode, see the commentary following 250.52(A)(1).

- (3) The power service accessible means external to enclosures as covered in 250.94 **Exception**
- (4) The nonflexible metallic power service raceway
- (5) The service equipment enclosure
- (6) The grounding electrode conductor or the grounding electrode conductor metal enclosure of the power service, or
- (7) The grounding electrode conductor or the grounding electrode of a building or structure disconnecting means that is connected to an electrode as covered in 250.32

A bonding device intended to provide a termination point for the grounding electrode conductor (intersystem bonding) shall not interfere with the opening of an equipment enclosure. A bonding device shall be mounted on non-removable parts. A bonding device shall not be mounted on a door or cover even if the door or cover is non-removable.

For purposes of this section, the mobile home service equipment or the mobile home disconnecting means, as described in 830.93, shall be considered accessible.

**(3) In Buildings or Structures Without an Intersystem Bonding Termination or Grounding Means.** If the building or structure served has no intersystem bonding termination or grounding electrode(s) means, as described in 830.100(B)(2), the grounding electrode conductor shall be connected to either of the following:

- (1) To any one of the individual electrodes described in 250.52(A)(1), (A)(2), (A)(3), or (A)(4)

- (2) If the building or structure served has no intersystem bonding termination or has no grounding means, as described in 830.100(B)(2) or (B)(3)(1), to any one of the individual electrodes described in 250.52(A)(7) and (A)(8), or to a ground rod or pipe not less than 1.5 m (5 ft) in length and 12.7 mm (½ in.) in diameter, driven, where practicable, into permanently damp earth and separated from lightning conductors as covered in 800.53 and at least 1.8 m (6 ft) from electrodes of other systems. Steam or hot water pipes or lightning-rod conductors shall not be employed as grounding electrodes for protectors, NIUs with integral protection, grounded metallic members, NIUs with metallic enclosures, and other equipment.

**(C) Electrode Connection.** Connections to grounding electrodes shall comply with 250.70.

**(D) Bonding of Electrodes.** A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the network-powered broadband communications system grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

*Exception:* At mobile homes as covered in 830.106.

**Informational Note No. 1:** See 250.60 for use of air terminals (lightning rods).

**Informational Note No. 2:** Bonding together of all separate electrodes limits potential differences between them and between their associated wiring systems.

A common error made in grounding network-powered broadband communications systems is connecting the cable sheath to a rod-type grounding electrode driven by the utility installer at a convenient location near the point of cable entry to the building, instead of bonding it to the electrical service grounding electrode system, service raceway, or other components that make up the grounding electrode system. A separate grounding electrode is permitted only if the building or structure has none of the grounding means described in 830.100(B).

Section 250.94 requires that a bonding means with not less than three termination points that is accessible and external to the service equipment be provided for making the bonding and grounding connection for other systems. One of the following means is permitted for existing installations:

1. Exposed nonflexible metallic raceways
2. An exposed grounding electrode conductor

3. An approved means for the external connection of a conductor (A 6 AWG copper conductor with one end bonded to the service raceway or equipment with about 6 in. exposed is acceptable.)

Proper bonding of the network-powered broadband communications system cable sheath to the electrical power grounding electrode is needed to prevent potential fire and shock hazards. The earth cannot be used as an equipment grounding conductor or bonding conductor, because it does not have the required low-impedance path. (See 250.54.)

Both network-powered broadband communications systems and power systems are subject to current surges as a result of, for example, induced voltages from lightning in the vicinity of the usually extensive outside distribution systems. Surges also result from switching operations on power systems. If the grounded conductors and parts of the two systems are not bonded by a low-impedance path, such line surges can raise the potential difference between the two systems to many thousands of volts. This can result in arcing between the two systems, for example, wherever the network-powered broadband communications system cable jacket contacts a grounded part, such as a metal water pipe or metal structural member, inside the building.

If a person is the interface between the two systems and the bonding has not been done in accordance with the *Code*, the high-voltage surge could result in electric shock. More common, however, is burnout of a television tuner, a part that is almost always an interface between the two systems. The tuner is connected to the power system ground through the grounded neutral of the power supply, even if the television set itself is not provided with an equipment grounding conductor.

Also see the commentary following 250.92(B) and 820.100(E).

### 830.106 Grounding and Bonding at Mobile Homes

**(A) Grounding.** Grounding shall comply with 830.106(A)(1) or (A)(2).

- (1) Where there is no mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the network-powered broadband communications cable, network interface unit, and primary protector ground shall be installed connected to a grounding electrode conductor or grounding electrode in accordance with 830.100(B)(3).
- (2) Where there is no mobile home disconnecting means grounded in accordance with 250.32 and located within

sight from, and not more than 9.0 m (30 ft) of, the exterior wall of the mobile home it serves, the network-powered broadband communications cable, network interface unit, and primary protector ground shall be installed connected to a grounding electrode in accordance with 830.100(B)(3).

**(B) Bonding.** The network-powered broadband communications cable grounding terminal, network interface unit grounding terminal, if present, and primary protector grounding terminal shall be bonded together with a copper bonding conductor not smaller than 12 AWG. The network-powered broadband communications cable grounding terminal, network interface unit grounding terminal, primary protector grounding terminal, or the grounding electrode shall be bonded to the metal frame or available grounding terminal of the mobile home with a copper bonding conductor not smaller than 12 AWG under any of the following conditions:

- (1) Where there is no mobile home service equipment or disconnecting means as in 830.106(A)
- (2) Where the mobile home is supplied by cord and plug

## V. Installation Methods Within Buildings

### 830.110 Raceways for Low- and Medium-Power Network-Powered Broadband Communications Cables

**(A) Raceways Recognized in Chapter 3.** Low- and medium-power network-powered broadband communications cables shall be permitted to be installed in any raceway included in Chapter 3. The raceways shall be installed in accordance with the requirements of Chapter 3.

**(B) Raceway Fill for Network-Powered Broadband Communications Cables.** Raceway fill for network-powered broadband communications cables shall comply with either (B)(1) or (B)(2).

**(1) Low-Power Network-Powered Broadband Communications Cables.** The raceway fill requirements of Chapters 3 and 9 shall not apply to low-power network-powered broadband communications cables.

**(2) Medium-Power Network-Powered Broadband Communications Cables.** Where medium-power network-powered broadband communications cables are installed in a raceway, the raceway fill requirements of Chapters 3 and 9 shall apply.

### 830.113 Installation of Network-Powered Broadband Communications Cables.

Installation of network-powered broadband communications cables shall comply with 830.113(A) through (H).

**(A) Listing.** Network-powered broadband communications cables installed in buildings shall be listed.

**(B) Fabricated Ducts Used for Environmental Air.** The following cables shall be permitted in ducts as described in 300.22(B) if they are directly associated with the air distribution system:

- (1) Up to 1.22 m (4 ft) of Type BLP cable
- (2) Types BLP, BMR, BLR, BM, BL, and BLX cables installed in raceways that are installed in compliance with 300.22(B)

Informational Note: For information on fire protection of wiring installed in fabricated ducts see 4.3.4.1 and 4.3.11.3.3 in NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(C) Other Spaces Used For Environmental Air (Plenums).** The following cables shall be permitted in other spaces used for environmental air as described in 300.22(C):

- (1) Type BLP cable
- (2) Type BLP cable installed in plenum communications raceway
- (3) Type BLP cable supported by open metallic cable trays or cable tray systems
- (4) Types BLP, BMR, BLR, BM, BL, and BLX cables installed in raceways that are installed in compliance with 300.22(C)
- (5) Types BLP, BMR, BLR, BM, BL, and BLX cables supported by solid bottom metal cable trays with solid metal covers in other spaces used for environmental air (plenums) as described in 300.22(C)

Informational Note: For information on fire protection of wiring installed in other spaces used for environmental air see 4.3.11.2, 4.3.11.4 and 4.3.11.5 of NFPA 90A-2009, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

**(D) Risers — Cables in Vertical Runs.** The following cables shall be permitted in vertical runs penetrating one or more floors and in vertical runs in a shaft:

- (1) Types BLP, BMR, and BLR cables
- (2) Types BLP and BLR cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. Riser cable routing assembly

Informational Note: See 830.26 for firestop requirements for floor penetrations.

**(E) Risers — Cables in Metal Raceways.** The following cables shall be permitted in a metal raceway in a riser with firestops at each floor:

- (1) Types BLP, BMR, BLR, BM, BL, and BLX cables
- (2) Types BLP, BLR, and BL cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway

Informational Note: See 830.26 for firestop requirements for floor penetrations.

**(F) Risers — Cables in Fireproof Shafts.** The following cables shall be permitted to be installed in fireproof riser shafts with firestops at each floor:

- (1) Types BLP, BMR, BLR, BM, BL, and BLX cables
- (2) Types BLP, BLR, and BL cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

Informational Note: See 830.26 for firestop requirements for floor penetrations.

**(G) Risers — One- and Two-Family Dwellings.** The following cables shall be permitted in one- and two-family dwellings:

- (1) Types BLP, BMR, BLR, BM, and BL cables and Types BL and BLX cables less than 10 mm (0.375 in.) in diameter
- (2) Types BLP, BLR, and BL cables installed in:
  - a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly

Informational Note: See 830.26 for firestop requirements for floor penetrations.

**(H) Other Building Locations.** The following cables and raceways shall be permitted to be installed in building locations other than those covered in 830.113(B) through (G):

- (1) Types BLP, BMR, BLR, BM, and BL cables
- (2) Types BLP, BMR, BLR, BM, BL, and BLX cables installed in a raceway
- (3) Types BLP, BLR, and BL cables

- a. Plenum communications raceway
  - b. Riser communications raceway
  - c. General-purpose communications raceway
  - d. Riser cable routing assembly
  - e. General-purpose cable routing assembly
- (4) Types BLX and BL cables less than 10 mm (0.375 in.) in diameter in one- and two-family dwellings
  - (5) Types BMU and BLU cables entering the building from outside and run in rigid metal conduit or intermediate metal conduit where the conduit is connected by a bonding conductor or grounding electrode conductor in accordance with 830.100(B)

Informational Note: This provision limits the length of Type BLX cable to 15 m (50 ft), while 830.90(B) requires that the primary protector, or NIU with integral protection, be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, or NIU with integral protection, Type BLX cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the entrance point.

- (6) A maximum length of 15 m (50 ft), within the building, of Type BLX cable entering the building from outside and terminating at an NIU or a primary protection location

### 830.133 Installation of Network-Powered Broadband Communications Cables and Equipment

Cable and equipment installations within buildings shall comply with 830.133(A) through (C), as applicable.

#### (A) Separation of Conductors.

##### (1) In Raceways, Cable Trays, Boxes, and Enclosures.

(a) *Low- and Medium-Power Network-Powered Broadband Communications Circuit Cables.* Low- and medium-power network-powered broadband communications cables shall be permitted in the same raceway, cable tray, or enclosure.

(b) *Low-Power Network-Powered Broadband Communications Circuit Cables with Optical Fiber Cables and Other Communications Cables.* Low-power network-powered broadband communications cables shall be permitted in the same raceway, cable tray, enclosure, or cable routing assembly with jacketed cables of any of the following circuits:

- (1) Communications circuits in compliance with Parts I and IV of Article 800
- (2) Nonconductive and conductive optical fiber cables in compliance with Parts I and IV of Article 770

- (3) Community antenna television and radio distribution systems in compliance with Parts I and IV of Article 820

(c) *Low-Power Network-Powered Broadband Communications Circuit Cables with Other Circuits.* Low-power network-powered broadband communications cables shall be permitted in the same raceway, cable tray, or enclosure with jacketed cables of any of the following circuits:

- (1) Class 2 and Class 3 remote-control, signaling, and power-limited circuits in compliance with Parts I and III of Article 725
- (2) Power-limited fire alarm systems in compliance with Parts I and III of Article 760

(d) *Medium-Power Network-Powered Broadband Communications Circuit Cables with Optical Fiber Cables and Other Communications Cables.* Medium-power network-powered broadband communications cables shall not be permitted in the same raceway, cable tray, enclosure or cable routing assembly with conductors of any of the following circuits:

- (1) Communications circuits in compliance with Parts I and IV of Article 800
- (2) Conductive optical fiber cables in compliance with Parts I and IV of Article 770
- (3) Community antenna television and radio distribution systems in compliance with Parts I and IV of Article 820

(e) *Medium-Power Network-Powered Broadband Communications Circuit Cables with Other Circuits.* Medium-power network-powered broadband communications cables shall not be permitted in the same raceway, cable tray, or enclosure with conductors of any of the following circuits:

- (1) Class 2 and Class 3 remote-control, signaling, and power-limited circuits in compliance with Parts I and III of Article 725
- (2) Power-limited fire alarm systems in compliance with Parts I and III of Article 760

(f) *Electric Light, Power, Class 1, Non-Powered Broadband Communications Circuit Cables.* Network-powered broadband communications cable shall not be placed in any raceway, cable tray, compartment, outlet box, junction box, or similar fittings with conductors of electric light, power, Class 1, or non-power-limited fire alarm circuit cables.

*Exception No. 1: Where all of the conductors of electric light, power, Class 1, non-power-limited fire alarm circuits are separated from all of the network-powered broadband communications cables by a permanent barrier or listed divider.*

This exception recognizes the use of a listed field-installed divider to separate the communication circuits from the power circuits.

*Exception No. 2: Power circuit conductors in outlet boxes, junction boxes, or similar fittings or compartments where such conductors are introduced solely for power supply to the network-powered broadband communications system distribution equipment. The power circuit conductors shall be routed within the enclosure to maintain a minimum 6-mm (0.25-in.) separation from network-powered broadband communications cables.*

**(2) Other Applications.** Network-powered broadband communications cable shall be separated at least 50 mm (2 in.) from conductors of any electric light, power, Class 1, and non-power-limited fire alarm circuits.

*Exception No. 1: Where either (1) all of the conductors of electric light, power, Class 1, and non-power-limited fire alarm circuits are in a raceway, or in metal-sheathed, metal-clad, nonmetallic-sheathed, Type AC, or Type UF cables, or (2) all of the network-powered broadband communications cables are encased in raceway.*

*Exception No. 2: Where the network-powered broadband communications cables are permanently separated from the conductors of electric light, power, Class 1, and non-power-limited fire alarm circuits by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the wire.*

**(B) Support of Network-Powered Broadband Communications Cables.** Raceways shall be used for their intended purpose. Network-powered broadband communications cables shall not be strapped, taped, or attached by any means to the exterior of any conduit or raceway as a means of support.

### 830.154 Applications of Network-Powered Broadband Communications System Cables

Permitted and nonpermitted applications of listed network-powered broadband communications system cables shall be

as indicated in Table 830.154(a). The permitted applications shall be subject to the installation requirements of 830.40, 830.110 and 830.113. The substitutions for network-powered broadband system cables listed in Table 830.154(b) shall be permitted.

Table 830.154(a) provides a summary of applications for the cable types covered in Article 830. Note that the permitted applications are a summary and are subject to the installation requirements of 830.113.

### 830.160 Bends

Bends in network broadband cable shall be made so as not to damage the cable.

## VI. Listing Requirements

### 830.179 Network-Powered Broadband Communications Equipment and Cables

Network-powered broadband communications equipment and cables shall be listed and marked in accordance with 830.179(A) or (B).

Article 830 permits three types of listed cable: coaxial, coaxial with a twisted pair of conductors, and fiber optical with a twisted pair of conductors. (See 830.1.) In the coaxial configuration, power and signal are carried on the coaxial center conductor. With coaxial and a twisted pair of conductors, the signal is carried on the coaxial center conductor, and the power is carried on the twisted pair. The configuration of fiber optic and twisted-pair conductors carries the signal on the fiber and the power on the twisted pair.

*Exception No. 1: This listing requirement shall not apply to community antenna television and radio distribution system coaxial cables that were installed prior to January 1, 2000, in accordance with Article 820 and are used for low-power network-powered broadband communications circuits.*

*Exception No. 2: Substitute cables for network-powered broadband communications cables shall be permitted as shown in Table 830.154(b).*

**(A) Network-Powered Broadband Communications Medium-Power Cables.** Network-powered broadband communications medium-power cables shall be factory-assembled cables consisting of a jacketed coaxial cable, a jacketed combination of coaxial cable and multiple individual conductors, or a jacketed combination of an optical fiber

**TABLE 830.154(a) Applications of Network-Powered Broadband Cables in Buildings**

		Cable Types						
		BLP	BLR	BL	BMR	BM	BLX	BMU, BLU
In fabricated ducts as described in 300.22(B)	In fabricated ducts as described in 300.22(B)	Y*	N	N	N	N	N	N
	In metal raceway that complies with 300.22(B)	Y*	Y*	Y*	Y*	Y*	Y*	N
In other spaces used for environmental air as described in 300.22(C)	In other spaces used for environmental air as described in 300.22(C)	Y*	N	N	N	N	N	N
	In metal raceway that complies with 300.22(C)	Y*	Y*	Y*	Y*	Y*	Y*	N
	In plenum communications raceways	Y*	N	N	N	N	N	N
	Supported by open metal cable trays	Y*	N	N	N	N	N	N
	Supported by solid bottom metal cable trays with solid metal covers	Y*	Y*	Y*	Y*	Y*	Y*	N
In risers	In vertical runs	Y*	Y*	N	Y*	N	N	N
	In metal raceways	Y*	Y*	Y*	Y*	Y*	Y*	N
	In fireproof shafts	Y*	Y*	Y*	Y*	Y*	Y*	N

	In riser cable routing assemblies	Y*	Y*	N	N	N	N	N
	In one- and two-family dwellings	Y*	Y*	Y*	Y*	Y*	Y*	N
Within buildings in other than air-handling spaces and risers	General	Y*	Y*	Y*	Y*	Y*	Y*	N
	In one- and two-family dwellings	Y*	Y*	Y*	Y*	Y*	Y*	N
	Supported by cable trays	Y*	Y*	Y*	Y*	Y*	N	N
	In rigid metal conduit and intermediate metal conduit	Y*	Y*	Y*	Y*	Y*	Y*	Y*
	In any raceway recognized in Chapter 3	Y*	Y*	Y*	Y*	Y*	Y*	N
	In plenum communications raceways	Y*	Y*	Y*	N	N	N	N
	In riser communications raceways	Y*	Y*	Y*	N	N	N	N
	In general purpose communications raceways	Y*	Y*	Y*	N	N	N	N
	In riser cable routing assemblies	Y*	Y*	Y*	N	N	N	N
	In general-purpose cable routing assemblies	Y*	Y*	Y*	N	N	N	N

Note: An “N” in the table indicates that the cable type is not permitted to be installed in the application. A “Y\*” indicates that the cable is permitted to be installed in the application, subject to the limitations described in 830.113.

Informational Note 1: Part V of Article 830 covers installation methods within buildings. This table covers the applications of listed network-powered broadband communications cables in buildings. The definition of point of entrance is in 830.2. Network-powered broadband communications cables entrance cables that have not emerged from the rigid metal conduit or intermediate metal conduit are not considered to be in the building.

Informational Note No. 2: For information on the restrictions to the installation of network-powered broadband communications cables in fabricated ducts see 830.113(B).

TABLE 830.154(b) Cable Substitutions

Cable Type	Permitted Cable Substitutions
BM	BMR
BLP	CMP, CL3P
BLR	CMP, CL3P, CMR, CL3R, BLP, BMR
BL	CMP, CMR, CM, CMG, CL3P, CL3R, CL3, BMR, BM, BLP, BLR
BLX	CMP, CMR, CM, CMG, CMX, CL3P, CL3R, CL3, CL3X, BMR, BM, BLP, BRP, BL

cable and multiple individual conductors. The insulation for the individual conductors shall be rated for 300 volts minimum. Cables intended for outdoor use shall be listed as suitable for the application. Cables shall be marked in accordance with 310.120.

A rating of 300 volts is necessary for the following reasons:

1. To coordinate with protector installation requirements (i.e., protectors are not required within a block unless the cable is exposed to over 300 volts)
2. To recognize the fact that primary protectors are designed to allow voltages below 300 to pass
3. To accommodate the voltages ordinarily found on a network-powered broadband communications circuit (voltage up to 150 volts rms)

**(1) Type BMR.** Type BMR cables shall be listed as being suitable for use in a vertical run in a shaft or from floor to floor and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2007, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

See the commentary following the informational note to 725.179(B).

**(2) Type BM.** Type BM cables shall be listed as being suitable for general-purpose use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

Informational Note: One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the UL Flame Exposure, Vertical Tray Flame Test in UL 1685-2007, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical*

*and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA Vertical Flame Test — Cables in Cable Trays, as described in CSA C22.2 No. 0.3-M-2001, *Test Methods for Electrical Wires and Cables*.

See the commentary following the informational note to 725.179(C).

**(3) Type BMU.** Type BMU cables shall be jacketed and listed as being suitable for outdoor underground use.

**(B) Network-Powered Broadband Communication Low-Power Cables.** Network-powered broadband communications low-power cables shall be factory-assembled cables consisting of a jacketed coaxial cable, a jacketed combination of coaxial cable and multiple individual conductors, or a jacketed combination of an optical fiber cable and multiple individual conductors. The insulation for the individual conductors shall be rated for 300 volts minimum. Cables intended for outdoor use shall be listed as suitable for the application. Cables shall be marked in accordance with 310.120.

**(1) Type BLP.** Type BLP cables shall be listed as being suitable for use in ducts, plenums, and other spaces used for environmental air and shall also be listed as having adequate fire-resistant and low smoke-producing characteristics.

Informational Note: One method of defining a cable that is low smoke-producing and fire resistant is that the cable exhibits a maximum peak optical density of 0.5 or less, an average optical density of 0.15 or less, and a maximum flame spread distance of 1.52 m (5 ft) or less when tested in accordance with NFPA 262-2007, *Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces*.

See the commentary following the informational note to 725.179(A).

**(2) Type BLR.** Type BLR cables shall be listed as being suitable for use in a vertical run in a shaft, or from floor to floor, and shall also be listed as having fire-resistant characteristics capable of preventing the carrying of fire from floor to floor.

Informational Note: One method of defining fire-resistant characteristics capable of preventing the carrying of fire from floor to floor is that the cables pass the requirements of ANSI/UL 1666-2007, *Standard Test for Flame Propagation Height of Electrical and Optical-Fiber Cable Installed Vertically in Shafts*.

See the commentary following the informational note to 725.179(B).

**(3) Type BL.** Type BL cables shall be listed as being suitable for general-purpose use, with the exception of risers and plenums, and shall also be listed as being resistant to the spread of fire.

**Informational Note:** One method of defining resistant to the spread of fire is that the cables do not spread fire to the top of the tray in the UL Flame Exposure, Vertical Tray Flame Test in UL 1685-2007, *Standard for Safety for Vertical-Tray Fire-Propagation and Smoke-Release Test for Electrical and Optical-Fiber Cables*. The smoke measurements in the test method are not applicable.

Another method of defining resistant to the spread of fire is for the damage (char length) not to exceed 1.5 m (4 ft 11 in.) when performing the CSA Vertical Flame Test — Cables in Cable Trays, as described in CSA C22.2 No. 0.3-2001, *Test Methods for Electrical Wires and Cables*.

See the commentary following the informational note to 725.179(C).

**(4) Type BLX.** Type BLX limited-use cables shall be listed as being suitable for use outside, for use in dwellings, and for use in raceways and shall also be listed as being resistant to flame spread.

**Informational Note:** One method of determining that cable is resistant to flame spread is by testing the cable to VW-1 (vertical-wire) flame test in ANSI/UL 1581-2001, *Reference Standard for Electrical Wires, Cables and Flexible Cords*.

**(5) Type BLU.** Type BLU cables shall be jacketed and listed as being suitable for outdoor underground use.

## I. General

### 840.1 Scope

This article covers premises-powered optical fiber-based broadband communications systems that provide any combination of voice, video, data, and interactive services through an optical network terminal (ONT).

Informational Note No. 1: A typical basic system configuration consists of an optical fiber cable to the premises (FTTP) supplying a broadband signal to an ONT that converts the broadband optical signal into component electrical signals, such as traditional telephone, video, high-speed internet, and interactive services. Powering of the ONT is typically accomplished through an ONT power supply unit (OPSU) and battery backup unit (BBU) that derive their power input from the available ac at the premises. The optical fiber cable is unpowered and may be nonconductive or conductive.

Informational Note No. 2: See 90.2(B)(4) for installations of premises-powered broadband communications systems that are not covered in this article.

Article 840 is new to the 2011 *Code*. Although similar to Article 830, which addresses network-powered broadband communications systems, Article 840 covers a new technology called premises-powered optical fiber-based broadband communications systems. This new article provides all of the requirements for premises-powered optical fiber-based broadband communications systems.

Premises-powered optical fiber-based broadband communications systems provide a wide array of subscriber services, including voice, video, data (such as Internet access), and interactive services through an optical network terminal (ONT).

Article 840 contains requirements for wiring both the inside and the outside of buildings. Other articles cover the wiring derived from the ONT into the premises. They include the following:

- Article 725 covers wiring of Class 2 and Class 3 circuits.
- Article 760 covers the wiring of fire alarm systems.
- Article 770 covers the installation of optical fiber cable.
- Article 800 covers communications (telephone) wiring.
- Article 820 covers coaxial cable installations for television signals.

### 840.2 Definitions

The definitions in Article 100 and 770.2, 800.2, and 820.2 shall apply. For purposes of this article, the following additional definitions apply.

**Fiber-to-the-Premises (FTTP).** Conductive or nonconductive optical cable that is either aerial, buried, or through a raceway and is terminated at an optical network terminal (ONT) and establishing a communications network.

**Optical Network Terminal (ONT).** A device that converts an optical signal into component signals, including voice, audio, video, data, wireless, and interactive service electrical, and is considered to be network interface equipment.

**Premises Communications Circuit.** The circuit that extends voice, audio, video, data, interactive services, telegraph (except radio), and outside wiring for fire alarm and burglar alarm from the service provider's ONT to the customer's communications equipment up to and including terminal equipment, such as a telephone, a fax machine, or an answering machine.

**Premises Community Antenna Television (CATV) Circuit.** The circuit that extends community antenna television (CATV) systems for audio, video, data, and interactive services from the service provider's ONT to the appropriate customer equipment.

### 840.3 Other Articles

**(A) Hazardous (Classified) Locations.** Premises-powered broadband communications circuits and equipment installed in a location that is classified in accordance with 500.5 and 505.5 shall comply with the applicable requirements of Chapter 5.

**(B) Equipment in Other Space Used for Environmental Air.** The requirements of 300.22(C) shall apply.

**(C) Output Circuits.** As appropriate for the services provided, the output circuits derived from the optical network terminal shall comply with the requirements of the following:

- (1) Installations of premises communications circuits — Article 800
- (2) Installations of premises community antenna television and radio distribution circuits — Article 820
- (3) Installations of optical fiber cables — Article 770
- (4) Installations of Class 2 and Class 3 circuits — Article 725
- (5) Installations of power-limited fire alarm circuits — Article 760

### 840.21 Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to electrical equipment shall not be denied by an accumulation of premises-powered broadband cables that prevents removal of panels, including suspended ceiling panels.

An excess accumulation of wires and cables can limit access to equipment by preventing the removal of access panels.

**840.24 Mechanical Execution of Work**

The requirements of 770.24, 800.24, and 820.24 shall apply.

Section 840.24 provides requirements for workmanship. Cable must be attached to or supported by the structure by cable ties, straps, clamps, hangers, and the like. The installation method must not damage the cable. In addition, the location of the cable must be carefully evaluated to ensure that activities and processes within the building do not damage the cable.

**840.25 Abandoned Cables**

The requirements of 770.25, 800.25, and 820.25 shall apply.

**840.26 Spread of Fire or Products of Combustion**

The requirements of 770.26, 800.26, and 820.26 shall apply.

**II. Cables Outside and Entering Buildings****840.44 Overhead Optical Fiber Cables**

Overhead optical fiber cables containing a non-current-carrying metallic member entering buildings shall comply with 840.44(A) and (B).

Composite premises-powered optical fiber-based broadband communications systems may contain sufficient energy to pose injurious or fatal electric shock hazards. For that reason, those types of systems are subject to requirements similar to those for other high-powered circuits.

Section 840.44 requires that conductor spans be of sufficient size and strength to maintain clearances and avoid possible contact with light or power conductors. Splices and joints must be made with approved connectors or other means that provide sufficient mechanical strength so that conductors are not weakened appreciably, which could cause them to break and come into contact with higher-voltage conductors.

**(A) On Poles and In-Span.** Where outside plant optical fiber cables and electric light or power conductors are supported by the same pole or are run parallel to each other in-span, the conditions described in 840.44(A)(1) through (A)(4) shall be met.

**(1) Relative Location.** Where practicable, the outside plant optical fiber cables shall be located below the electric light or power conductors.

**(2) Attachment to Cross-Arms.** Attachment of outside plant optical fiber cables to a cross-arm that carries electric light or power conductors shall not be permitted.

**(3) Climbing Space.** The climbing space through outside plant optical fiber cables shall comply with the requirements of 225.14(D).

**(4) Clearance.** Supply service drops of 0 to 750 volts running above and parallel to premises-powered broadband communications service drops shall have a minimum separation of 300 mm (12 in.) at any point in the span, including the point of and at their attachment to the building. Clearance of not less than 1.0 m (40 in.) shall be maintained between the two services at the pole.

**(B) Above Roofs.** Outside plant optical fiber cables shall have a vertical clearance of not less than 2.5 m (8 ft) from all points of roofs above which they pass.

*Exception No. 1: The requirement of 840.44(B) shall not apply to auxiliary buildings, such as garages and the like.*

*Exception No. 2: A reduction in clearance above only the overhanging portion of the roof, to not less than 450 mm (18 in.), shall be permitted if (a) not more than 1.2 m (4 ft) of premises-powered broadband communications service-drop cable passes above the roof overhang, and (b) the cable is terminated at a through- or above-the-roof raceway or approved support.*

*Exception No. 3: Where the roof has a slope of not less than 100 mm in 300 mm (4 in. in 12 in.), a reduction in clearance to not less than 900 mm (3 ft) shall be permitted.*

Informational Note: For additional information regarding overhead wires and cables, see ANSI C2-2007, *National Electric Safety Code, Part 2, Safety Rules for Overhead Lines*.

**840.47 Underground Optical Fiber Cables Entering Buildings**

Underground optical fiber cables entering buildings shall comply with 830.47(A) through (C).

**(A) Class 1 or Non-Power-Limited Fire Alarm Circuits.** Underground optical fiber cables with a non-current-carrying metallic member entering buildings with electric light, power, Class 1, or non-power-limited fire alarm circuit conductors in a raceway, handhole enclosure, or manhole shall be located in a section separated from such conductors by means of brick, concrete, or tile partitions or by means of a suitable barrier.

**(B) Direct-Buried Cables and Raceways.** Direct-buried optical fiber cables with a non-current-carrying metallic

member shall be separated by at least 300 mm (12 in.) from conductors of any electric light, power, or non-power-limited fire alarm circuit conductors or Class 1 circuit.

*Exception No. 1: Where electric service conductors are installed in raceways or have metal cable armor.*

*Exception No. 2: Where electric light or power branch-circuit or feeder conductors, non-power-limited fire alarm circuit conductors, or Class 1 circuit conductors are installed in a raceway or in metal-sheathed, metal-clad, or Type UF or Type USE cables.*

**(C) Mechanical Protection.** Direct-buried cable, conduit, or other raceway shall be installed to have a minimum cover of 150 mm (6 in.).

### 840.48 Unlisted Cables and Raceways Entering Building

The requirements of 770.48 shall apply.

## III. Protection

### 840.90 Protective Devices

The requirements of 800.90 shall apply.

### 840.93 Grounding or Interruption

**(A) Non-Current-Carrying Metallic Members of Optical Fiber Cables.** Non-current-carrying metallic members of optical fiber cables entering a building or terminating on the outside of a building shall comply with 770.93(A) or (B).

**(B) Communications Cables.** The grounding or interruption of the metallic sheath of communications cable shall comply with 800.93.

**(C) Coaxial Cables.** Where the ONT is installed inside or outside of the building, with coaxial cables terminating at the ONT, and is either entering, exiting, or attached to the outside of the building, 820.93 shall apply.

## IV. Grounding Methods

### 840.100 ONT and Optical Fiber Cable Grounding

Grounding required for protection of the ONT and optical fiber cable shall comply with 770.100, 800.100, or 820.100, as applicable.

### 840.101 Premises Circuits Not Leaving the Building

Where the ONT is served by a nonconductive optical fiber cable, or where any non-current-carrying metallic member is interrupted by an insulating joint or equivalent device,

and circuits that terminate at the ONT and are completely contained within the building (i.e., they do not exit the building), 840.101(A), (B), and (C) shall apply, as applicable.

The requirements of 840.101 apply where the ONT is served by a nonconductive optical fiber cable, or where any non-current-carrying metallic member is interrupted by an insulating joint or equivalent device, and circuits that terminate at the ONT and are completely contained within the building.

Section 840.101(A)(3) permits the coaxial shield to be grounded through the ONT as long as the ONT grounding connection is permanent or to an equipment grounding conductor through a listed grounding device that will retain the grounding connection if the ONT is unplugged.

**(A) Coaxial Cable Shield Grounding.** The shield of coaxial cable shall be grounded by one of the following:

- (1) Any of the methods described in 820.100 or 820.106
- (2) A fixed connection to an equipment grounding conductor as described in 250.118
- (3) Connection to the ONT grounding terminal provided that the terminal is connected to ground by one of the methods described in 820.100 or 820.106, or to an equipment grounding conductor through a listed grounding device that will retain the ground connection if the ONT is unplugged

**(B) Communications Circuit Grounding.** Communications circuits shall not be required to be grounded.

**(C) ONT Grounding.** The ONT shall not be required to be grounded unless required by its listing. If the coaxial cable shield is separately grounded as described in 840.101(A)(1) or 840.101(A)(2), the use of a cord and plug for the connection to the ONT grounding connection shall be permitted.

Informational Note: Where required to be grounded, a listed device that extends the equipment grounding conductor from the receptacle to the ONT equipment grounding terminal is permitted. Sizing of the extended equipment grounding conductor is covered in Table 250.122.

### 840.103 Equipment Grounding

The grounding of the ONT shall be as required by the equipment listing.

### 840.106 Grounding and Bonding at Mobile Homes

**(A) Grounding.** Grounding shall comply with (1) and (2).

- (1) Where there is no mobile home service equipment located within 9.0 m (30 ft) of the exterior wall of the mobile

home it serves, the ONT, if required to be grounded, shall be connected to a grounding electrode in accordance with 840.100. Premises communications circuits and premises CATV circuits shall be grounded in accordance with 840.93.

(2) Where there is no mobile home disconnecting means grounded in accordance with 250.32 and located within 9.0 m (30 ft) of the exterior wall of the mobile home it serves, the ONT, if required to be grounded, shall be connected to a grounding electrode in accordance with 800.100(B)(3). Premises communications circuits and premises CATV circuits shall be grounded in accordance with 840.93.

**(B) Bonding.** The ONT grounding terminal or grounding electrode shall be connected to the metal frame or available grounding terminal of the mobile home with a copper conductor not smaller than 12 AWG under any of the following conditions:

(1) Where there is no mobile home service equipment or disconnecting means as specified in 840.106(A).

(2) Where the mobile home is supplied by cord and plug.

## V. Installation Methods Within Buildings

### 840.110 Raceways for Premises-Powered Broadband Communications Optical Fiber Cables

The requirements of 770.110 shall apply.

### 840.113 Installation Past the ONT

Installation of premises communications circuits and premises coaxial circuits shall comply with 840.113(A) and (B).

**(A) Premises Communications Circuits.** Premises communications wires and cables installed in a building from the ONT shall be listed in accordance with 800.179, and the installation shall comply with 800.113 and 800.133.

**(B) Premises Community Antenna Television (CATV) Circuits.** Premises CATV coaxial cables installed in a building from the ONT shall be listed in accordance with 820.179, and the installation shall comply with 820.113 and 820.133.

### 840.133 Installation of Optical Fibers and Electrical Conductors Associated with Premises-Powered Broadband Communications Systems

The requirements of 770.133 shall apply.

### 840.154 Applications of Listed Optical Fiber Cables and Raceways

The requirements of 770.154 shall apply.

## VI. Listing Requirements

### 840.170 Equipment and Cables

Premises-powered broadband communications systems equipment and cables shall comply with 840.170(A) through (D).

**(A) Optical Network Terminal.** The ONT and applicable grounding means shall be listed for application with premises-powered broadband communications systems.

Informational Note No. 1: One way to determine applicable requirements is to refer to UL 60950-1-2003, *Standard for Safety of Information Technology Equipment*, UL 498A-2008, *Current Taps and Adapters*, or UL 467-2007, *Grounding and Bonding Equipment*.

Informational Note No. 2: There are no requirements on the ONT and its grounding methodologies except for those covered by the listing of the product.

**(B) Optical Fiber Cables.** Optical fiber cables shall be listed in accordance with 770.179(A) through (D) and shall be marked in accordance with Table 770.179.

**(C) Premises Communications Circuits.** Premises communications wires and cables connecting to the ONT shall be listed in accordance with 800.179. Communications raceways associated with the premises-powered broadband communications system shall be listed in accordance with 800.182.

**(D) Premises Community Antenna Television (CATV) Circuits.** Premises community antenna television (CATV) coaxial cables connecting to the ONT shall be listed in accordance with 820.179. Applicable grounding means shall be listed for application with premises-powered broadband communications systems.

Section 840.170(D) requires the ONT grounding means to be listed for use with premises-powered broadband communications systems.

As the adoption and use of the *NEC* has increased in areas of the world where the metric system is the standard, providing a means to allow for the use of electrical products with metric measurements or designations has become necessary to allow for assimilation of *NEC* requirements in the metric world. For every provision that specifies the size of a conduit or tubing with a cylindrical cross-section size, two size designations, referred to as metric designator and trade size, are given per Table 300.1(C). This designation affects all metal, nonmetallic, rigid, and flexible conduit and tubing types that have a cylindrical cross section. For example, ½-in. conduit and tubing are referred to as metric

designator 16 or trade size ½; ¾ in. is metric designator 21 or trade size ¾; 4 in. is metric designator 103 or trade size 4, and so forth.

For further information on metrication and the revised way of giving conduit and tubing sizes in the *NEC*, see 90.9 and its associated commentary and the commentary following Table 300.1(C).

Because conduits and tubing from different manufacturers have different internal diameters for the same trade size, Table 4 provides the diameter and the actual area of different conduit and tubing types at fill percentages of 100, 60, 53 (one wire), 31 (two wires), and 40 (more than two wires). The 60 percent fill is provided in Table 4 to correlate with Note 4 (found in the Notes to Tables section of this chapter) to the conduit and tubing fill tables, which permits conduit or tubing nipples 24 in. or less in length to have a conductor fill of up to 60 percent. Separate sections in Table 4 cover metal, nonmetallic, rigid, and flexible conduit and tubing types. Examples of how to use the conduit and tubing conductor fill tables are included in the commentary both here and in Informative Annex C.

Informative Annex C contains conductor fill tables for each of 12 types of conduit and tubing. The Informative Annex C tables — which are based on the dimensions given in Tables 1 and 4 of Chapter 9 for conduit and tubing fill and on the dimensions for conductors in Table 5 of Chapter 9 — provide conductor fill information based on the specific conduit or tubing and on the conductor insulation type, size, and stranding characteristics. Examples of how to use these tables are included in the commentary both here and in Informative Annex C.

**TABLE 1 Percent of Cross Section of Conduit and Tubing for Conductors**

Number of Conductors	All Conductor Types
1	53
2	31
Over 2	40

Informational Note No. 1: Table 1 is based on common conditions of proper cabling and alignment of conductors where the length of the pull and the number of bends are within reasonable limits. It should be recognized that, for certain conditions, a larger size conduit or a lesser conduit fill should be considered.

Table 1 establishes the maximum fill permitted for the circular conduit and tubing types. It is the basis for Table 4 and for the information on conduit and tubing fill provided in the Informative Annex C tables. Informational Note No. 1 advises that factors such as the length of the run or the number and total radius of bends can increase the difficulty of pulling conductors into the raceway and in extreme cases could result in damage to conductor insulation. To mitigate such adverse effects and to facilitate the ease of installing the conductors in the conduit or tubing, it is recommended that where a difficult installation is anticipated, the maximum number of conductors permitted not be installed, or the size of the conduit or tubing be increased by at least one trade size larger than the minimum required by the *Code*. Experienced personnel can attest to the wisdom of this advice.

Informational Note No. 2: When pulling three conductors or cables into a raceway, if the ratio of the raceway (inside diameter) to the conductor or cable (outside diameter) is between 2.8 and 3.2, jamming can occur. While jamming can occur when pulling four or more conductors or cables into a raceway, the probability is very low.

Informational Note No. 2 warns of another potential pitfall associated with pulling conductors into conduit or tubing. Conductor jamming may occur during the installation (pulling) of conductors into a conduit even if fill allowances of 40 percent are observed. During the installation of three conductors or cables into the raceway, one conductor could slip between the other two conductors. This is more likely to take place at bends, where the raceway may be slightly oval.

As an example, Table C.1 in Informative Annex C permits three 8 AWG conductors in trade size ½ electrical metallic tubing (EMT). An 8 AWG conductor has an outside diameter (OD) of 0.216 in. (from Table 5), and a ½ in. EMT has an internal diameter (ID) of 0.622 in. (from Table 4).

The EMT in a straight run has an internal diameter of 0.622 in., but because it may not be round at a bend, one conductor may slip between the other two and cause a jam as the conductors exit the bend. In a straight run, assuming no variation in the EMT's internal diameter or in a conductor's outside diameter, one conductor usually cannot slip between the other two, because the total of the outside diameters of the conductors ( $3 \times 0.216 \text{ in.} = 0.648 \text{ in.}$ ) is greater than the EMT's internal diameter of 0.622 in. At a bend, however, the major internal diameter of the raceway may increase due to bending, particularly in tubing, to a di-

ameter slightly larger than 0.648 in., permitting the middle conductor to be pulled between the outer two conductors. As the conductors exit the bend and the raceway returns to its normal shape with an internal diameter of 0.622 in., the conductors may jam. This can also occur in straight runs where the ratio of the raceway's internal diameter to the conductor's outside diameter approaches 3. The jam ratio is calculated as follows:

$$\text{Jam ratio} = \frac{\text{ID of raceway}}{\text{OD of conductor}} = \frac{0.622}{0.216} = 2.88$$

To avoid difficult conductor installations and potential conductor insulation damage due to jamming within the conduit or tubing, a jam ratio between 2.8 and 3.2 should be avoided.

### Notes to Tables

- (1) See Informative Annex C for the maximum number of conductors and fixture wires, all of the same size (total cross-sectional area including insulation) permitted in trade sizes of the applicable conduit or tubing.
- (2) Table 1 applies only to complete conduit or tubing systems and is not intended to apply to sections of conduit or tubing used to protect exposed wiring from physical damage.

The maximum fill requirements do not apply to short sections of conduit or tubing used for the physical protection of conductors and cables. Cables are commonly protected from physical damage by conduit or tubing sleeves sized to enable the cable to be passed through with relative ease without injuring or abrading the protective jacket of the cable. The requirement of 300.5(D)(1) regarding physical protection of direct-buried cables and conductors as they emerge from below grade is an example of conduit or tubing being used as a protective sleeve and not as a continuous raceway system per 300.12. However, a fitting is required on the end(s) of the conduit or tubing to protect the conductors or cables from abrasion. [See 300.15(C).]

- (3) Equipment grounding or bonding conductors, where installed, shall be included when calculating conduit or tubing fill. The actual dimensions of the equipment grounding or bonding conductor (insulated or bare) shall be used in the calculation.

All insulated, covered, and bare conductors occupy space within a raceway. Therefore, all installed conductors must be included in the raceway fill calculation, including non-current-carrying conductors such as equipment grounding conductors, bonding conductors, and bonding jumpers. The

only exception to this rule is the addition of an equipment grounding conductor permitted in trade size  $\frac{3}{8}$  flexible metal conduit (see the note to Table 348.22). The dimensions of bare conductors are given in Table 8.

- (4) Where conduit or tubing nipples having a maximum length not to exceed 600 mm (24 in.) are installed between boxes, cabinets, and similar enclosures, the nipples shall be permitted to be filled to 60 percent of their total cross-sectional area, and 310.15(B)(3)(a) adjustment factors need not apply to this condition.
- (5) For conductors not included in Chapter 9, such as multiconductor cables and optical fiber cables, the actual dimensions shall be used.

For conductors not included in Chapter 9, such as high-voltage types, the cross-sectional area can be calculated in the following manner, using the actual dimensions of each conductor:

$$\text{cross-sectional area} = d^2 \text{ cmil}$$

Where:

$d$  = outside diameter of a conductor (including insulation) [1 in. = 1000 mil (1 mil = 0.001 in.)]

cmil = circular mil, a unit measure of area equal to  $\pi/4$  (3.1416/4 = 0.7854) square mil. In other words, 1 cmil = 0.7854 square mil.

#### Calculation Example

Three 15-kV single conductors are to be installed in rigid metal conduit (RMC). The outside diameter of each conductor measures  $1\frac{5}{8}$  in., or 1.625 in. What size RMC will accommodate the three conductors?

#### Solution

STEP 1. Find the cross-sectional area within the conduit to be displaced by the three conductors:

$$\begin{aligned} 1.625 \text{ in.} \times 1.625 \text{ in.} \times 0.7854 \times 3 \\ = 6.2218 \text{ in.}^2 \text{ or } 6.222 \text{ in.}^2 \end{aligned}$$

STEP 2. Determine the correct conduit size to accommodate the three conductors. Table 1 allows 40 percent conduit fill for three or more conductors, and Table 4 indicates that 40 percent of trade size 5 RMC is  $8.085 \text{ in.}^2$ . Thus, trade size 5 RMC will accommodate three 15-kV single conductors.

- (6) For combinations of conductors of different sizes, use Table 5 and Table 5A for dimensions of conductors and Table 4 for the applicable conduit or tubing dimensions.

The following two examples demonstrate how to calculate the minimum trade size conduit or tubing required for conductors of different sizes.

#### Calculation Example 1

A 200-ampere feeder is routed in various wiring methods [electrical metallic tubing (EMT); rigid polyvinyl chloride conduit (PVC), Schedule 40; and rigid metal conduit (RMC)] from the main switchboard in one building to a distribution panelboard in another building. The circuit consists of four 4/0 AWG XHHW copper conductors and one 6 AWG XHHW copper conductor. Select the proper trade size for the various types of conduit and tubing to be used for the feeder.

#### Solution

All the raceways for this example require conduit fill to be calculated according to Table 1 in Chapter 9, which permits conduit fill to a maximum of 40 percent where more than two conductors are installed. (See 344.22 for RMC, 352.22 for PVC, and 358.22 for EMT.) Table 1, Note 6 refers to Table 5 for the area required for each insulated conductor. Note 6 also refers to Table 4 for selection of the appropriate trade size conduit or tubing. Table 4 contains the allowable cross-sectional area for conduit and tubing based on conductor-occupied space (40 percent maximum in this example).

STEP 1. Calculate the total area occupied by the conductors, using the approximate areas listed in Table 5:

Four 4/0 AWG XHHW:

$$4 \times 0.3197 \text{ in.}^2 = 1.2788 \text{ in.}^2$$

One 6 AWG XHHW:

$$1 \times 0.0590 \text{ in.}^2 = 0.0590 \text{ in.}^2$$

$$\text{Total area} = 1.3378 \text{ in.}^2 \text{ or } 1.338 \text{ in.}^2$$

STEP 2. Determine the proper trade size EMT, RMC, and PVC (Schedule 40) from Table 4. The portion of this feeder installed in EMT requires a minimum trade size 2, which has  $1.342 \text{ in.}^2$  of available space for over two conductors. The minimum required space is  $1.338 \text{ in.}^2$ , which is less than the trade size 2 EMT 40 percent fill. RMC also requires a minimum trade size 2, because trade size 2 RMC has  $1.363 \text{ in.}^2$  of available space for over two conductors. PVC (Schedule 40), however, requires a minimum trade size  $2\frac{1}{2}$ . Trade size 2 PVC has  $1.316 \text{ in.}^2$  allowable space for over two conductors and is less than the  $1.338 \text{ in.}^2$  required for this combination of conductors. Therefore, it is necessary to increase the PVC size to  $2\frac{1}{2}$  trade size, the next standard size increment.

#### Calculation Example 2

Determine the minimum size rigid metal conduit (RMC) allowed for the 10 mixed conductor sizes and types described below.

Quantity	Wire Size and Type	Cross-Sectional Area of Each Wire (from Table 5)	Cross-Sectional Area
4	12 AWG THWN	0.0133	0.0532
3	8 AWG TW	0.0437	0.1311
3	6 AWG THW	0.0726	0.2178
			Total 0.4021

**Solution**

The “Over 2 Wires” column in Table 4 indicates that 40 percent of a trade size 1¼ RMC is 0.610 in.<sup>2</sup>. Therefore, trade size 1¼ is the minimum size RMC allowed for this combination of 10 conductors.

- (7) When calculating the maximum number of conductors permitted in a conduit or tubing, all of the same size (total cross-sectional area including insulation), the next higher whole number shall be used to determine the maximum number of conductors permitted when the calculation results in a decimal of 0.8 or larger.

**Calculation Example**

Determine how many 10 AWG THHN conductors are permitted in a trade size 1¼ rigid metal conduit (RMC).

**Solution**

Table 1 permits 40 percent fill for over two conductors. From Table 4, 40 percent fill for trade size 1¼ RMC is 0.610 in., and from Table 5, the cross-sectional area of a 10 AWG THHN conductor is 0.0211 in.<sup>2</sup>. The number of conductors permitted is calculated as follows:

$$\frac{0.610 \text{ in.}^2}{0.0211 \text{ in.}^2 \text{ per conductor}} = 28.910 \text{ conductors}$$

Based on the maximum allowable fill, the number of 10 AWG THHN conductors in trade size 1¼ RMC cannot exceed 28. However, in accordance with Note 7, an increase to the next whole number of 29 conductors is permitted in this case, because 0.910 is greater than 0.8, which is the

benchmark for determining whether an increase to the next whole number for the maximum number of conductors is permitted. Although increasing the total to 29 conductors results in the raceway fill exceeding 40 percent, the amount by which it is exceeded is a fraction of 1 percent and will not adversely affect the installation of the conductors. This number of conductors does have to be addressed from a mutual heating effect in accordance with 310.15(B)(3)(a). Bear in mind that this is the maximum number of conductors permitted, and in accordance with Informational Note No. 1 to Table 1 in Chapter 9, an installation with fewer than the maximum number of conductors allowed may be prudent.

Verification of this solution can be found in Informative Annex C, Table C.8, which lists twenty-nine 10 AWG THWN conductors as the maximum number permitted in trade size 1¼ RMC. Several examples of the application of Note 7 are found in the Informative Annex C tables. Where the calculation results in a decimal value less than 0.8, the maximum number of conductors permitted is based on the next lower whole number.

- (8) Where bare conductors are permitted by other sections of this *Code*, the dimensions for bare conductors in Table 8 shall be permitted.
- (9) A multiconductor cable or flexible cord of two or more conductors shall be treated as a single conductor for calculating percentage conduit fill area. For cables that have elliptical cross sections, the cross-sectional area calculation shall be based on using the major diameter of the ellipse as a circle diameter.

Prior to the 2005 *Code*, Table 2 (on p. 1310) was included in Article 344 as Table 344.24. The requirements on minimum bending radius (depending on the type of bending equipment employed) apply to all the rigid, flexible, metallic, and nonmetallic conduit and tubing types. Because of its widespread application for all the circular conduit and tubing types (refer to Section XX.24 of applicable article), this table is more appropriately located in Chapter 9 and referred to in the respective conduit and tubing articles.

## Notes:

- These resistance values are valid **only** for the parameters as given. Using conductors having coated strands, different stranding type, and, especially, other temperatures changes the resistance.
- Equation for temperature change:  $R_2 = R_1 [1 + \alpha (T_2 - 75)]$  where  $\alpha_{cu} = 0.00323$ ,  $\alpha_{AL} = 0.00330$  at 75°C.
- Conductors with compact and compressed stranding have about 9 percent and 3 percent, respectively, smaller bare conductor diameters than those shown. See Table 5A for actual compact cable dimensions.
- The IACS conductivities used: bare copper = 100%, aluminum = 61%.
- Class B stranding is listed as well as solid for some sizes. Its overall diameter and area is that of its circumscribing circle.

Informational Note: The construction information is in accordance with NEMA WC/70-2009 or ANSI/UL 1581-2001. The resistance is calculated in accordance with National Bureau of Standards Handbook 100, dated 1966, and Handbook 109, dated 1972.

In addition to traditional wire sizes expressed as American Wire Gage (AWG), circular mil (cmil) area, or thousands of circular mil (kcmil) area, wire is available with its cross-sectional area expressed in square millimeters (mm<sup>2</sup>).

The *Code* requires that insulated conductors be marked with their sizes and that the sizes be expressed in either AWG or circular mil area. [See 110.6 and 310.120(A)(4).] The *Code* allows no exceptions to either of these two requirements. Because Article 310 does not specifically prohibit optional marking on insulated conductors, the *Code* permits square millimeter (mm<sup>2</sup>) markings on conductors, but only if they are in addition to the required traditional markings of AWG or circular mil area.

According to IEEE/ASTM SI 10-2002, *Standard for Use of the International System of Units (SI): The Modern Metric System*, conversion from circular mils to square meters is done by multiplying circular mils by  $5.067075 \times 10^{-10}$ . However, because square millimeters, rather than square meters, is the standard marking for wire size and because the reciprocal is more appropriate for this conversion, a simpler conversion factor to convert from square millimeters to circular mils (approximately) follows:

$$k = 1973.53 \frac{\text{circular mils}}{\text{mm}^2}$$

The following example provides a comparison of the square millimeter wire gauge to traditional wire sizes.

#### Calculation Example

What traditional wire size does the size 125 mm<sup>2</sup> represent (approximately)?

#### Solution

$$\begin{aligned} \text{Circular mil area} &= \text{wire size (mm}^2\text{)} \times \text{conversion factor} \\ &= 125 \text{ mm}^2 \times 1973.53 \frac{\text{circular mils}}{\text{mm}^2} \\ &= 246,691 \text{ circular mils or } 246.691 \text{ kcmil} \end{aligned}$$

Therefore, the 125 mm<sup>2</sup> wire is larger than 4/0 AWG (211.6 kcmil) but smaller than a 250-kcmil conductor.

**Conclusion:** If a 125 mm<sup>2</sup> wire is determined to be the minimum or recommended size conductor, it is important to understand that size 250 kcmil would be the only Table 8 conductor with equivalent cross-sectional area because 4/0 AWG is simply not enough metal. It is important, however, to note that the 250-kcmil conductor ampacity could not be used for a 125 mm<sup>2</sup> conductor, because the metric conductor size is smaller. The 4/0 AWG ampacity can be used, or the ampacity can be calculated under engineering supervision.

## Notes:

1. These values are based on the following constants: UL-Type RHH wires with Class B stranding, in cradled configuration. Wire conductivities are 100 percent IACS copper and 61 percent IACS aluminum, and aluminum conduit is 45 percent IACS. Capacitive reactance is ignored, since it is negligible at these voltages. These resistance values are valid only at 75°C (167°F) and for the parameters as given, but are representative for 600-volt wire types operating at 60 Hz.

2. *Effective Z* is defined as  $R \cos(\theta) + X \sin(\theta)$ , where  $\theta$  is the power factor angle of the circuit. Multiplying current by effective impedance gives a good approximation for line-to-neutral voltage drop. Effective impedance values shown in this table are valid only at 0.85 power factor. For another circuit power factor (*PF*), effective impedance (*Ze*) can be calculated from *R* and  $X_L$  values given in this table as follows:  $Ze = R \times PF + X_L \sin[\arccos(PF)]$ .

Voltage-drop calculations using the dc-resistance formula are not always accurate for ac circuits, especially for those with a less-than-unity power factor or for those that use conductors larger than 2 AWG. Table 9 allows *Code* users to perform simple ac voltage-drop calculations. Table 9 was compiled using the Neher–McGrath ac-resistance calculation method, and the values presented are both reliable and conservative. This table contains completed calculations of effective impedance ( $Z$ ) for the average ac circuit with an 85 percent power factor (see Calculation Example 1). If calculations with a different power factor are necessary, Table 9 also contains the appropriate values of inductive reactance and ac resistance (see Example 2). The basic assumptions and the limitations of Table 9 are as follows:

1. Capacitive reactance is ignored.
2. There are three conductors in a raceway.
3. The calculated voltage-drop values are approximate.
4. For circuits with other parameters, the Neher–McGrath ac-resistance calculation method is used.

#### Calculation Example 1

A feeder has a 100-ampere continuous load. The system source is 240 volts, 3 phase, and the supplying circuit breaker is 125 amperes. The feeder is in a trade size 1¼ aluminum conduit with three 1 AWG THHN copper conductors operating at their maximum temperature rating of 75°C. The circuit length is 150 ft, and the power factor is 85 percent. Using Table 9, determine the approximate voltage drop of this circuit.

#### Solution

STEP 1. Find the approximate line-to-neutral voltage drop. Using the Table 9 column “Effective  $Z$  at 0.85  $PF$  for Uncoated Copper Wires,” select aluminum conduit and size 1 AWG copper wire. Use the given value of 0.16 ohm per 1000 ft in the following formula:

$$\begin{aligned}\text{Voltage drop}_{(\text{line-to-neutral})} &= \frac{\text{table value}}{\text{length}} \times \frac{\text{circuit load}}{1000 \text{ ft}} \\ &= 0.16 \text{ ohm} \times \frac{150 \text{ ft}}{1000 \text{ ft}} \times 100 \text{ A} \\ &= 2.40 \text{ V}\end{aligned}$$

STEP 2. Find the line-to-line voltage drop:

$$\begin{aligned}\text{Voltage drop}_{(\text{line-to-line})} &= \text{voltage drop}_{(\text{line-to-neutral})} \times \sqrt{3} \\ &= 2.40 \text{ V} \times 1.732 \\ &= 4.157 \text{ V}\end{aligned}$$

STEP 3. Find the voltage present at the load end of the circuit:

$$240 \text{ V} - 4.157 \text{ V} = 235.84 \text{ V}$$

#### Calculation Example 2

A 270-ampere continuous load is present on a feeder. The circuit consists of a single 4-in. PVC conduit with three 600-kcmil XHHW/USE aluminum conductors fed from a 480-volt, 3-phase, 3-wire source. The conductors are operating at their maximum rated temperature of 75°C. If the power factor is 0.7 and the circuit length is 250 ft, is the voltage drop excessive?

#### Solution

STEP 1. Using the Table 9 column “ $X_L$  (Reactance) for All Wires,” select PVC conduit and the row for size 600 kcmil. A value of 0.039 ohm per 1000 ft is given as this  $X_L$ . Next, using the column “Alternating-Current Resistance for Aluminum Wires,” select PVC conduit and the row for size 600 kcmil. A value of 0.036 ohm per 1000 ft is given as this  $R$ .

STEP 2. Find the angle representing a power factor of 0.7. Using a calculator with trigonometric functions or a trigonometric function table, find the arccosine ( $\cos^{-1}$ )  $\theta$  of 0.7, which is 45.57 degrees. For this example, call this angle  $\theta$ .

STEP 3. Find the impedance ( $Z$ ) corrected to 0.7 power factor ( $Z_c$ ):

$$\begin{aligned}Z_c &= (R \times \cos \theta) + (X_L \times \sin \theta) \\ &= (0.036 \times 0.7) + (0.039 \times 0.7141) \\ &= 0.0252 + 0.0279 \\ &= 0.0531 \text{ ohm to neutral}\end{aligned}$$

STEP 4. As in Calculation Example 1, find the approximate line-to-neutral voltage drop:

$$\begin{aligned}\text{Voltage drop}_{(\text{line-to-neutral})} &= Z_c \times \frac{\text{circuit length}}{1000 \text{ ft}} \times \text{circuit load} \\ &= 0.0531 \times \frac{250 \text{ ft}}{1000 \text{ ft}} \times 270 \text{ A} \\ &= 3.584 \text{ V}\end{aligned}$$

STEP 5. Find the approximate line-to-line voltage drop:

$$\begin{aligned}\text{Voltage drop}_{(\text{line-to-line})} &= \text{voltage drop}_{(\text{line-to-neutral})} \times \sqrt{3} \\ &= 3.584 \text{ V} \times 1.732 \\ &= 6.208 \text{ V}\end{aligned}$$

STEP 6. Find the approximate voltage drop expressed as a percentage of the circuit voltage:

$$\begin{aligned}\text{Percentage voltage drop}_{(\text{line-to-line})} &= \frac{6.208 \text{ V}}{480 \text{ V}} \times 100 \\ &= 1.29\% \text{ VD}\end{aligned}$$

STEP 7. Find the voltage present at the load end of the circuit:

$$480 \text{ V} - 6.208 \text{ V} = 473.8 \text{ V}$$

**Conclusion:** According to 210.19(A)(1), Informational Note No. 4, this voltage drop does not appear to be excessive.

**TABLE 10 Conductor Stranding**

**Tables 11(A) and 11(B)**

For listing purposes, Table 11(A) and Table 11(B) provide the required power source limitations for Class 2 and Class 3 power sources. Table 11(A) applies for alternating-current sources, and Table 11(B) applies for direct-current sources.

The power for Class 2 and Class 3 circuits shall be either (1) inherently limited, requiring no overcurrent protection, or (2) not inherently limited, requiring a combination of power source and overcurrent protection. Power sources designed for interconnection shall be listed for the purpose.

As part of the listing, the Class 2 or Class 3 power source

shall be durably marked where plainly visible to indicate the class of supply and its electrical rating. A Class 2 power source not suitable for wet location use shall be so marked.

*Exception: Limited power circuits used by listed information technology equipment.*

Overcurrent devices, where required, shall be located at the point where the conductor to be protected receives its supply and shall not be interchangeable with devices of higher ratings. The overcurrent device shall be permitted as an integral part of the power source.

**TABLE 11(A) Class 2 and Class 3 Alternating-Current Power Source Limitations**

Power Source		Inherently Limited Power Source (Overcurrent Protection Not Required)				Not Inherently Limited Power Source (Overcurrent Protection Required)			
		Class 2			Class 3	Class 2		Class 3	
Source voltage $V_{max}$ (volts) (see Note 1)		0 through 20*	Over 20 and through 30*	Over 30 and through 150	Over 30 and through 100	0 through 20*	Over 20 and through 30*	Over 30 and through 100	Over 100 and through 150
Power limitations $VA_{max}$ (volt- amperes) (see Note 1)		—	—	—	—	250 (see Note 3)	250	250	N.A.
Current limitations $I_{max}$ (amperes) (see Note 1)		8.0	8.0	0.005	$150/V_{max}$	$1000/V_{max}$	$1000/V_{max}$	$1000/V_{max}$	1.0
Maximum overcurrent protection (amperes)		—	—	—	—	5.0	$100/V_{max}$	$100/V_{max}$	1.0
Power source maximum nameplate rating	VA (volt- amperes)	$5.0 \times V_{max}$	100	$0.005 \times V_{max}$	100	$5.0 \times V_{max}$	100	100	100
	Current (amperes)	5.0	$100/V_{max}$	0.005	$100/V_{max}$	5.0	$100/V_{max}$	$100/V_{max}$	$100/V_{max}$

\*Voltage ranges shown are for sinusoidal ac in indoor locations or where wet contact is not likely to occur.

For nonsinusoidal or wet contact conditions, see Note 2.

**TABLE 11(B) Class 2 and Class 3 Direct-Current Power Source Limitations**

Power Source		Inherently Limited Power Source (Overcurrent Protection Not Required)					Not Inherently Limited Power Source (Overcurrent Protection Required)			
		Class 2				Class 3	Class 2		Class 3	
Source voltage $V_{max}$ (volts) (see Note 1)		0 through 20*	Over 20 and through 30*	Over 30 and through 60*	Over 60 and through 150	Over 60 and through 100	0 through 20*	Over 20 and through 60*	Over 60 and through 100	Over 100 and through 150
Power limitations $VA_{max}$ (volt- amperes) (see Note 1)		—	—	—	—	—	250 (see Note 3)	250	250	N.A.
Current limitations $I_{max}$ (amperes) (see Note 1)		8.0	8.0	$150/V_{max}$	0.005	$150/V_{max}$	$1000/V_{max}$	$1000/V_{max}$	$1000/V_{max}$	1.0
Maximum overcurrent protection (amperes)		—	—	—	—	—	5.0	$100/V_{max}$	$100/V_{max}$	1.0
Power source maximum nameplate rating	VA (volt- amperes)	$5.0 \times V_{max}$	100	100	$0.005 \times V_{max}$	100	$5.0 \times V_{max}$	100	100	100
	Current (amperes)	5.0	$100/V_{max}$	$100/V_{max}$	0.005	$100/V_{max}$	5.0	$100/V_{max}$	$100/V_{max}$	$100/V_{max}$

\*Voltage ranges shown are for continuous dc in indoor locations or where wet contact is not likely to occur.

For interrupted dc or wet contact conditions, see Note 4.

**Notes for Tables 11(A) and 11(B)**

1.  $V_{max}$ ,  $I_{max}$ , and  $VA_{max}$  are determined with the current-limiting impedance in the circuit (not bypassed) as follows:

$V_{max}$ : Maximum output voltage regardless of load with rated input applied.

$I_{max}$ : Maximum output current under any noncapacitive load, including short circuit, and with overcurrent protection bypassed if used. Where a transformer limits the output current,  $I_{max}$  limits apply after 1 minute of operation. Where a current-limiting impedance, listed for the purpose, or as part of a listed product, is used in combination with a non-power-limited transformer or a stored energy source, e.g., storage battery, to limit the output current,  $I_{max}$  limits apply after 5 seconds.

$VA_{max}$ : Maximum volt-ampere output after 1 minute of operation regardless of load and overcurrent protection bypassed if used.

2. For nonsinusoidal ac,  $V_{max}$  shall not be greater than 42.4 volts peak. Where wet contact (immersion not included) is likely to occur, Class 3 wiring methods shall be used or  $V_{max}$  shall not be greater than 15 volts for sinusoidal ac and 21.2 volts peak for nonsinusoidal ac.

3. If the power source is a transformer,  $VA_{max}$  is 350 or less when  $V_{max}$  is 15 or less.

4. For dc interrupted at a rate of 10 to 200 Hz,  $V_{max}$  shall not be greater than 24.8 volts peak. Where wet contact (immersion not included) is likely to occur, Class 3 wiring methods shall be used, or  $V_{max}$  shall not be greater than 30 volts for continuous dc; 12.4 volts peak for dc that is interrupted at a rate of 10 to 200 Hz.

Because there is a listing requirement for Class 2 and Class 3 power supplies in 725.121, Tables 11(A) and 11(B) are not directly referenced by the typical installer. The information has been retained in Chapter 9 to provide direction for organizations properly equipped and qualified to evaluate and list these products.

### Tables 12(A) and 12(B)

For listing purposes, Tables 12(A) and 12(B) provide the required power source limitations for power-limited fire alarm sources. Table 12(A) applies for alternating-current sources, and Table 12(B) applies for direct-current sources. The power for power-limited fire alarm circuits shall be either (1) inherently limited, requiring no overcurrent protection, or (2) not inherently limited, requiring the power to be limited by a combination of power source and overcurrent protection.

As part of the listing, the PLFA power source shall be durably marked where plainly visible to indicate that it is a power-limited fire alarm power source. The overcurrent device, where required, shall be located at the point where the conductor to be protected receives its supply and shall not be interchangeable with devices of higher ratings. The overcurrent device shall be permitted as an integral part of the power source.

Because there is a listing requirement for power-limited fire alarm (PLFA) power supplies in 760.121, this information is not directly referenced by the typical installer. Tables 12(A) and 12(B) provide direction for organizations properly equipped and qualified to evaluate and list these products.

**TABLE 12(A) PLFA Alternating-Current Power Source Limitations**

Power Source		Inherently Limited Power Source (Overcurrent Protection Not Required)			Not Inherently Limited Power Source (Overcurrent Protection Required)		
Circuit voltage $V_{max}$ (volts) (see Note 1)		0 through 20	Over 20 and through 30	Over 30 and through 100	0 through 20	Over 20 and through 100	Over 100 and through 150
Power limitations $VA_{max}$ (volt-amperes) (see Note 1)		—	—	—	250 (see Note 2)	250	N.A.
Current limitations $I_{max}$ (amperes) (see Note 1)		8.0	8.0	$150/V_{max}$	$1000/V_{max}$	$1000/V_{max}$	1.0
Maximum overcurrent protection (amperes)		—	—	—	5.0	$100/V_{max}$	1.0
Power source maximum nameplate ratings	VA (volt-amperes)	$5.0 \times V_{max}$	100	100	$5.0 \times V_{max}$	100	100
	Current (amperes)	5.0	$100/V_{max}$	$100/V_{max}$	5.0	$100/V_{max}$	$100/V_{max}$

**TABLE 12(B) PLFA Direct-Current Power Source Limitations**

Power Source		Inherently Limited Power Source (Overcurrent Protection Not Required)			Not Inherently Limited Power Source (Overcurrent Protection Required)		
Circuit voltage $V_{max}$ (volts) (see Note 1)		0 through 20	Over 20 and through 30	Over 30 and through 100	0 through 20	Over 20 and through 100	Over 100 and through 150
Power limitations $VA_{max}$ (volt-amperes) (see Note 1)		—	—	—	250 (see Note 2)	250	N.A.
Current limitations $I_{max}$ (amperes) (see Note 1)		8.0	8.0	$150/V_{max}$	$1000/V_{max}$	$1000/V_{max}$	1.0
Maximum overcurrent protection (amperes)		—	—	—	5.0	$100/V_{max}$	1.0
Power source maximum nameplate ratings	VA (volt-amperes)	$5.0 \times V_{max}$	100	100	$5.0 \times V_{max}$	100	100
	Current (amperes)	5.0	$100/V_{max}$	$100/V_{max}$	5.0	$100/V_{max}$	$100/V_{max}$

### Notes for Tables 12(A) and 12(B)

1.  $V_{max}$ ,  $I_{max}$ , and  $VA_{max}$  are determined as follows:

$V_{max}$ : Maximum output voltage regardless of load with rated input applied.

$I_{max}$ : Maximum output current under any noncapacitive load, including short circuit, and with overcurrent protection bypassed if used. Where a transformer limits the output current,  $I_{max}$  limits apply after 1 minute of operation. Where a current-limiting impedance, listed for the purpose, is used in combination with a nonpower-limited transformer or a stored energy source, e.g., storage battery, to limit the output current,  $I_{max}$  limits apply after 5 seconds.

$VA_{max}$ : Maximum volt-ampere output after 1 minute of operation regardless of load and overcurrent protection bypassed if used. Current limiting impedance shall not be bypassed when determining  $I_{max}$  and  $VA_{max}$ .

2. If the power source is a transformer,  $VA_{max}$  is 350 or less when  $V_{max}$  is 15 or less.

# Informative Annex

## Product Safety Standards

*Informative Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This informative annex contains explanatory material, numbered to correspond with the applicable text paragraphs.*

This informative annex provides a list of product safety standards used for product listing where that listing is required by this *Code*. It is recognized that this list is current at the time of publication but that new standards or modifications to existing standards can occur at any time while this edition of the *Code* is in effect.

This informative annex does not form a mandatory part of the requirements of this *Code* but is intended only to provide *Code* users with informational guidance about the product characteristics about which *Code* requirements have been based.

A key element of a safe and *Code*-compliant electrical installation is adherence to product installation requirements imposed by product-testing organizations as part of their evaluation of an electrical product. Section 110.3(B) requires compliance with the installation and use instructions included with listed and labeled products. Numerous requirements in the *Code* specify the use of listed products. For those *Code* requirements where product listing is mandatory, Informative Annex A is a compilation of applicable product safety standards. It is important to understand that the product safety standards included in Informative Annex A are only those for which the *Code* has a mandatory listing

requirement. Many other safety standards are associated with products that do not have a mandatory listing or labeling requirement in the *Code*. For more information on product standards, consult the product directories available from testing organizations.

Product safety standards, installation codes such as the *NEC*, and qualified electrical inspection are separate but not mutually exclusive components of the North American electrical safety system. The effectiveness of this system strongly depends on a close working relationship among the organizations responsible for the development of product standards and installation codes and the electrical inspection community. In addition, proper electrical installations by *qualified persons* (see definition in Article 100) trained on the installation codes and application of listed products is a key component of this interdependent system that places public safety as its primary objective. All of these components must be in place for the electrical safety system to be effective.

The function of Informative Annex A is to provide users of the *Code* with the name, number, and developing organization for all product standards related to mandatory *Code* requirements that require the use of listed products. For more information on listing and labeling, see the commentary following 110.3(B).

Product Standard Name	Product Standard Number

Roof and Gutter De-Icing Cable Units	UL 1588
Room Air Conditioners	UL 484
Rotating Electrical Machines – General Requirements	UL 1004-1
Safety of Information Technology Equipment–Safety — Part 1: General Requirements	UL 60950-1
Schedule 40 and 80 Rigid PVC Conduit and Fittings	UL 651
Sealed Wire Connector Systems	UL 486D
Seasonal and Holiday Decorative Products	UL 588
Secondary Protectors for Communications Circuits	UL 497A
Self-Ballasted Lamps and Lamp Adapters	UL 1993
Service-Entrance Cables	UL 854
Smoke Detectors for Fire Alarm Signaling Systems	UL 268
Specialty Transformers	UL 506
Splicing Wire Connectors	UL 486C
Stage and Studio Lighting	UL 1573
Standby Batteries	UL 1989
Stationary Engine Generator Assemblies	UL 2200
Strut-Type Channel Raceways and Fittings	UL 5B
Supplemental Requirements for Extra-Heavy Wall Reinforced Thermosetting Resin Conduit (RTRC) and Fittings	UL 1684A
Surface Metal Raceways and Fittings	UL 5
Surface Raceways and Fittings for Use with Data, Signal and Control Circuits	UL 5C
Surge Arresters — Gapped Silicon-Carbide Surge Arresters for AC Power Circuits	IEEE C62.1
Surge Arresters — Metal-Oxide Surge Arresters for AC Power Circuits	IEEE C62.11
Swimming Pool Pumps, Filters, and Chlorinators	UL 1081
Switchboards	UL 891
Telephone Equipment	UL 1459
Thermally Protected Motors	UL 1004-3
Transfer Switch Equipment	UL 1008
Transient Voltage Surge Suppressors	UL 1449
Underfloor Raceways and Fittings	UL 884
Underwater Luminaires and Submersible Junction Boxes	UL 676
Uninterruptible Power Systems	UL 1778
Vacuum Cleaners, Blower Cleaners, and Household Floor Finishing Machines	UL 1017
Waste Disposers	UL 430
Wire Connectors	UL 486A-486B
Wireways, Auxiliary Gutters, and Associated Fittings	UL 870

# Informative Annex

## Application Information for Ampacity Calculation

*This informative annex is not a part of the requirements of this NFPA document but is included for informational purposes only.*

**B.310.15(B)(1) Equation Application Information.** This informative annex provides application information for ampacities calculated under engineering supervision.

The data in Informative Annex B are based on calculations using the Neher–McGrath conductor ampacity formula. The use of this method to calculate conductor ampacity is permitted under engineering supervision per 310.15(A)(1) and 310.15(C). The formula is found in 310.15(C).

Although conductor ampacities calculated using this formula may exceed those found in a table of allowable ampacities, such as Table 310.15(B)(16), the limitations for connecting to equipment terminals specified in 110.14(C) have to be followed. For equipment 600 volts and under, the ampacities used with equipment terminals are based on Table 310.15(B)(16). See the commentary following 110.14(C) and 310.15(C).

**B.310.15(B)(2) Typical Applications Covered by Tables.**

Typical ampacities for conductors rated 0 through 2000 volts are shown in Table B.310.15(B)(2)(1) through Table B.310.15(B)(2)(10). Table B.310.15(B)(2)(11) provides the adjustment factors for more than three current-carrying conductors in a raceway or cable with load diversity. Underground electrical duct bank configurations, as detailed in Figure B.310.15(B)(2)(3), Figure B.310.15(B)(2)(4), and Figure B.310.15(B)(2)(5), are utilized for conductors rated 0 through 5000 volts. In Figure B.310.15(B)(2)(2) through Figure B.310.15(B)(2)(5), where adjacent duct banks are used, a separation of 1.5 m (5 ft) between the centerlines of the closest ducts in each bank or 1.2 m (4 ft) between the extremities of the concrete envelopes is sufficient to prevent

derating of the conductors due to mutual heating. These ampacities were calculated as detailed in the basic ampacity paper, AIEE Paper 57-660, *The Calculation of the Temperature Rise and Load Capability of Cable Systems*, by J. H. Neher and M. H. McGrath. For additional information concerning the application of these ampacities, see IEEE/ICEA Standard S-135/P-46-426, *Power Cable Ampacities*, and IEEE Standard 835-1994, *Standard Power Cable Ampacity Tables*.

Typical values of thermal resistivity ( $\rho$ ) are as follows:

Average soil (90 percent of USA) = 90

Concrete = 55

Damp soil (coastal areas, high water table) = 60

Paper insulation = 550

Polyethylene (PE) = 450

Polyvinyl chloride (PVC) = 650

Rubber and rubber-like = 500

Very dry soil (rocky or sandy) = 120

*Thermal resistivity*, as used in this informative annex, refers to the heat transfer capability through a substance by conduction. It is the reciprocal of thermal conductivity and is normally expressed in the units  $^{\circ}\text{C}\cdot\text{cm}/\text{watt}$ . For additional information on determining soil thermal resistivity ( $\rho$ ), see ANSI/IEEE Standard 442-1996, *Guide for Soil Thermal Resistivity Measurements*.

If other factors remain the same, a soil resistivity higher than 90 reduces ampacities to values below those listed in Tables

B.310.15(B)(2)(5) through B.310.15(B)(2)(10) for underground ampacity. Conversely, a load factor less than 100 percent increases ampacities if other factors remain the same. See B.310.15(B)(7) for allowable adjustments if the load factor is less than 100 percent. Reduced load factors are used in Informational Note Figures B.310.15(B)(2)(3) through B.310.15(B)(2)(5).

**B.310.15(B)(3) Criteria Modifications.** Where values of load factor and Rho are known for a particular electrical duct bank installation and they are different from those shown in a specific table or figure, the ampacities shown in the table or figure can be modified by the application of factors derived from the use of Figure B.310.15(B)(2)(1).

Where two different ampacities apply to adjacent portions of a circuit, the higher ampacity can be used beyond the point of transition, a distance equal to 3 m (10 ft) or 10 percent of the circuit length **calculated** at the higher ampacity, whichever is less.

The information provided in B.310.15(B)(3) on how to address different conductor ampacities that apply to adjacent portions of a circuit is also specified in the exception to 310.15(A)(2). See the commentary following that exception.

Exhibit B.1 illustrates an installation where a change in the burial depth results in an analysis of whether a modification to the conductor ampacity is necessary. If that portion deeper than 30 in. does not exceed 25 percent of the total run length, no decrease in ampacity is required, even if part of the run is more than 30 in. deep, which is the maximum depth assumed in Figure B.310.15(B)(2)(2), Note 1, to maintain the accuracy of the tables.

**EXHIBIT B.1** The presence of a drain pipe results in a change of burial depth for that portion of the electrical installation under the drain pipe.

Where the burial depth of direct burial or electrical duct bank circuits are modified from the values shown in a figure or table, ampacities can be modified as shown in (a) and (b) as follows.

(a) Where burial depths are increased in part(s) of an electrical duct run to avoid underground obstructions, no decrease in ampacity of the conductors is needed, provided the total length of parts of the duct run increased in depth to avoid obstructions is less than 25 percent of the total run length.

(b) Where burial depths are deeper than shown in a specific underground ampacity table or figure, an ampacity de-rating factor of 6 percent per increased 300 mm (foot) of depth for all values of Rho can be utilized. No rating change is needed where the burial depth is decreased.

For example, in accordance with Table B.310.15(B)(2)(7) and Figure B.310.15(B)(2)(2), the ampacity of six parallel runs of 500 kcmil, Type XHHW copper conductors [as shown in Detail 3 in Figure B.310.15(B)(2)(2)], where  $Rho = 90$ , is  $6 \times 273$  amperes = 1638 amperes at a depth measuring no more than 30 in. to the top duct in the bank. If the burial depth is 6 ft, the ampacity is calculated as follows:  $1638 \text{ amperes} - (3.5 \times 0.06 \times 1638 \text{ amperes}) = 1294$  amperes.

**B.310.15(B)(4) Electrical Ducts.** The term *electrical duct(s)* is defined in 310.60.

**B.310.15(B)(5) Table B.310.15(B)(2)(6) and Table B.310.15(B)(2)(7).**

(a) To obtain the ampacity of cables installed in two electrical ducts in one horizontal row with 190-mm (7.5-in.) center-to-center spacing between electrical ducts, similar to Figure B.310.15(B)(2)(2), Detail 1, multiply the ampacity shown for one duct in Table B.310.15(B)(2)(6) and Table B.310.15(B)(2)(7) by 0.88.

(b) To obtain the ampacity of cables installed in four electrical ducts in one horizontal row with 190-mm (7.5-in.) center-to-center spacing between electrical ducts, similar to Figure B.310.15(B)(2)(2), Detail 2, multiply the ampacity shown for three electrical ducts in Table B.310.15(B)(2)(6) and Table B.310.15(B)(2)(7) by 0.94.

The underground ampacity tables [Tables B.310.15(B)(2)(5) through B.310.15(B)(2)(10)] are based on the 7.5-in. center-to-center spacing illustrated in Figure B.310.15(B)(2)(2). Although moving directly buried cables or electrical ducts farther apart will increase ampacities, the effect is

surprisingly small. One calculation indicates that two side-by-side electrical ducts buried 30 in. below grade would have to be spaced about 5 ft apart before they could be considered single electrical ducts as shown in Detail 1, Figure B.310.15(B)(2)(2). Decreasing the burial depth, decreasing the thermal resistivity of the earth or other surrounding medium, and decreasing the load factor — each has a much greater effect in increasing ampacity than does increasing the horizontal spacing.

**B.310.15(B)(6) Electrical Ducts Used in Figure B.310.15(B)(2)(2).** If spacing between electrical ducts, as shown in Figure B.310.15(B)(2)(2), is less than specified in Figure B.310.15(B)(2)(2), where electrical ducts enter equipment enclosures from underground, the ampacity of conductors contained within such electrical ducts need not be reduced.

**B.310.15(B)(7) Examples Showing Use of Figure B.310.15(B)(2)(1) for Electrical Duct Bank Ampacity Modifications.** Figure B.310.15(B)(2)(1) is used for interpolation or extrapolation for values of Rho and load factor for cables installed in electrical ducts. The upper family of curves shows the variation in ampacity and Rho at unity load factor in terms of  $I_1$ , the ampacity for Rho = 60, and 50 percent load factor. Each curve is designated for a particular

ratio  $I_2/I_1$ , where  $I_2$  is the ampacity at Rho = 120 and 100 percent load factor.

The lower family of curves shows the relationship between Rho and load factor that will give substantially the same ampacity as the indicated value of Rho at 100 percent load factor.

As an example, to find the ampacity of a 500-kcmil copper cable circuit for six electrical ducts as shown in Table B.310.15(B)(2)(5): At the Rho = 60, LF = 50,  $I_1 = 583$ ; for Rho = 120 and LF = 100,  $I_2 = 400$ . The ratio  $I_2/I_1 = 0.686$ . Locate Rho = 90 at the bottom of the chart and follow the 90 Rho line to the intersection with 100 percent load factor where the equivalent Rho = 90. Then follow the 90 Rho line to  $I_2/I_1$  ratio of 0.686 where  $F = 0.74$ . The desired ampacity =  $0.74 \times 583 = 431$ , which agrees with the table for Rho = 90, LF = 100.

To determine the ampacity for the same circuit where Rho = 80 and LF = 75, using Figure B.310.15(B)(2)(1), the equivalent Rho = 43,  $F = 0.855$ , and the desired ampacity =  $0.855 \times 583 = 498$  amperes. Values for using Figure B.310.15(B)(2)(1) are found in the electrical duct bank ampacity tables of this informative annex.

Where the load factor is less than 100 percent and can be verified by measurement or calculation, the ampacity of electrical duct bank installations can be modified as shown. Different values of Rho can be accommodated in the same manner.

**TABLE B.310.15(B)(2)(11) Adjustment Factors for More Than Three Current-Carrying Conductors in a Raceway or Cable with Load Diversity**

Number of Conductors*	Percent of Values in Tables as Adjusted for Ambient Temperature if Necessary
4 – 6	80
7 – 9	70
10 – 24	70**
25 – 42	60**
43 – 85	50**

\*Number of conductors is the total number of conductors in the raceway or cable adjusted in accordance with 310.15(B)(4) and (5).

\*\*These factors include the effects of a load diversity of 50 percent.

Informational Note: The ampacity limit for 10 through 85 current-carrying conductors is based on the following equation. For more than 85 conductors, special calculations are required that are beyond the scope of this table.

$$A_2 = \left[ \sqrt{\frac{0.5N}{E}} \times (A_1) \right] \text{ or } A_1, \text{ whichever is less}$$

where:

$A_1$  = ampacity from Table 310.15(B)(16), Table 310.15(B)(18), Table B.310.15(B)(2)(1), Table B.310.15(B)(2)(6), or Table B.310.15(B)(2)(7) multiplied by the appropriate adjustment factor from Table B.310.15(B)(2)(11).

$N$  = total number of conductors used to select adjustment factor from Table B.310.15(B)(2)(11)

$E$  = number of conductors carrying current simultaneously in the raceway or cable

$A_2$  = ampacity limit for the current-carrying conductors in the raceway or cable

### Example 1

Calculate the ampacity limit for twelve 14 AWG THWN current-carrying conductors (75°C) in a raceway that contains 24 conductors that may, at different times, be current-carrying.

$$\begin{aligned} A_2 &= \sqrt{\frac{(0.5)(24)}{12}} \times 20(0.7) \\ &= 14 \text{ amperes (i.e., 50 percent diversity)} \end{aligned}$$

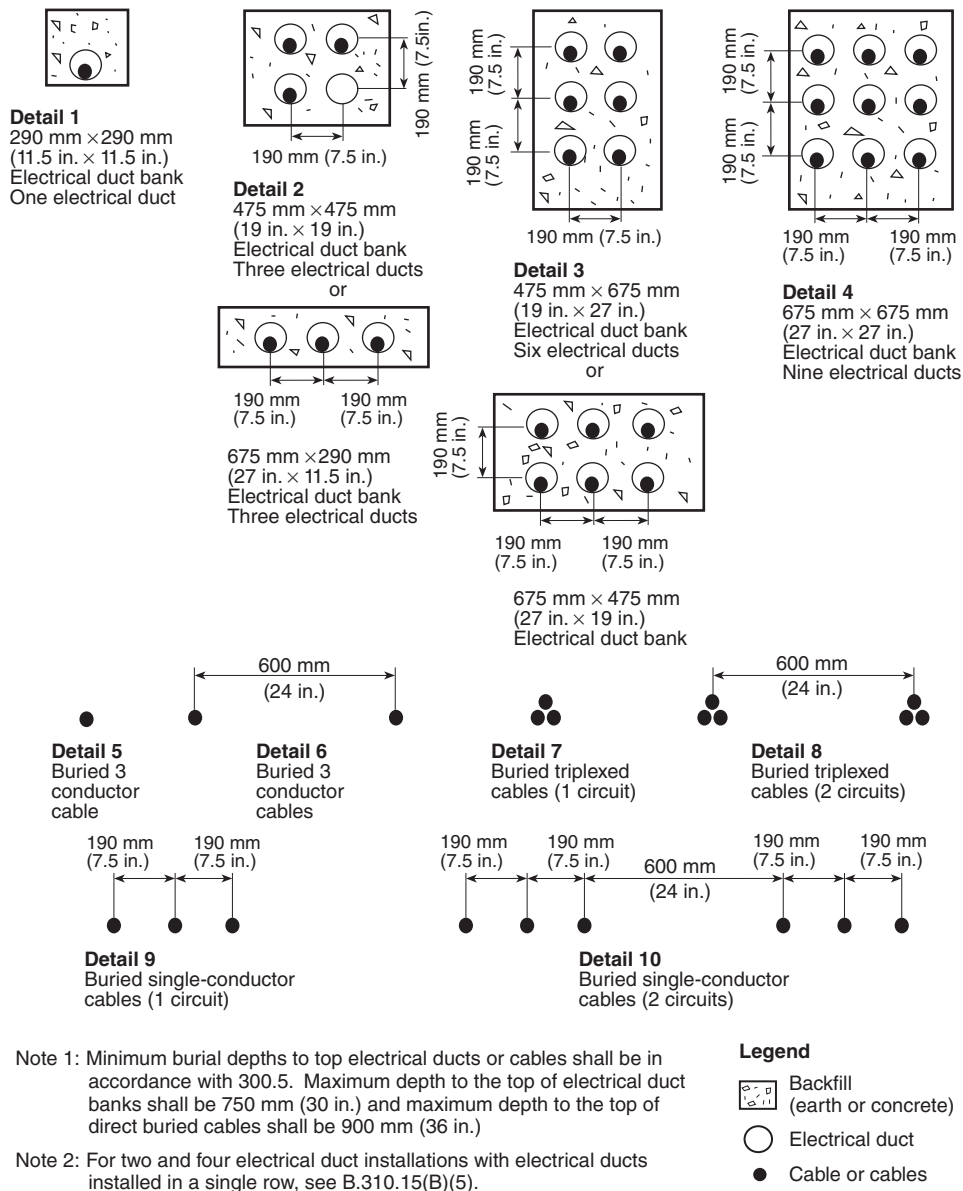

### Example 2

Calculate the ampacity limit for eighteen 14 AWG THWN current-carrying conductors (75°C) in a raceway that contains 24 conductors that may, at different times, be current-carrying.

$$A_2 = \sqrt{\frac{(0.5)(24)}{18}} \times 20(0.7) = 11.5 \text{ amperes}$$

**FIGURE B.310.15(B)(2)(1) Interpolation Chart for Cables in a Duct Bank**  $I_1$  = ampacity for  $Rho = 60, 50$  LF;  $I_2$  = ampacity for  $Rho = 120, 100$  LF (load factor); desired ampacity =  $F \times I_1$ .

Note 1: Minimum burial depths to top electrical ducts or cables shall be in accordance with 300.5. Maximum depth to the top of electrical duct banks shall be 750 mm (30 in.) and maximum depth to the top of direct buried cables shall be 900 mm (36 in.).

Note 2: For two and four electrical duct installations with electrical ducts installed in a single row, see B.310.15(B)(5).

**FIGURE B.310.15(B)(2)(2) Cable Installation Dimensions for Use with Table B.310.15(B)(2)(5) Through Table B.310.15(B)(2)(10).**

Design Criteria  
Neutral and Equipment  
Grounding conductor (EGC)  
Duct = 150 mm (6 in.)  
Phase Ducts = 75 to 125 mm (3 to 5 in.)  
Conductor Material = Copper  
Number of Cables per Duct = 3

Number of Cables per Phase = 9  
Rho concrete = Rho Earth – 5  
Rho PVC Duct = 650  
Rho Cable Insulation = 500  
Rho Cable Jacket = 650

Notes:

1. Neutral configuration per 300.5(I), Exception No. 2, for isolated phase installations in nonmagnetic ducts.
2. Phasing is A, B, C in rows or columns. Where magnetic electrical ducts are used, conductors are installed A, B, C per electrical duct with the neutral and all equipment grounding conductors in the same electrical duct. In this case, the 6-in. trade size neutral duct is eliminated.
3. Maximum harmonic loading on the neutral conductor cannot exceed 50 percent of the phase current for the ampacities shown in the table.
4. Metallic shields of Type MV-90 cable shall be grounded at one point only where using A, B, C phasing in rows or columns.

\*Limited to 75°C conductor temperature.

**INFORMATIONAL NOTE FIGURE B.310.15(B)(2)(4)**  
Ampacities of Single Insulated Conductors Rated 0 through 5000 Volts in Nonmagnetic Underground Electrical Ducts (One Conductor per Electrical Duct), Four Single-Conductor Cables per Phase Based on Ambient Earth Temperature of 20°C (68°F), Conductor Temperature 75°C (167°F).

Design Criteria  
 Neutral and Equipment  
 Grounding Conductor (EGC)  
 Duct = 150 mm (6 in.)  
 Phase Ducts = 75 mm (3 in.)  
 Conductor Material = Copper  
 Number of Cables per Duct = 1

Number of Cables per Phase = 5  
 Rho Concrete = Rho Earth = 5  
 Rho PVC Duct = 650  
 Rho Cable Insulation = 500  
 Rho Cable Jacket = 650

Notes:

1. Neutral configuration per 300.5(I), Exception No. 2.
2. Maximum harmonic loading on the neutral conductor cannot exceed 50 percent of the phase current for the ampacities shown in the table.
3. Metallic shields of Type MV-90 cable shall be grounded at one point only.

Size kcmil	TYPES RHW, THHW, THW, THWN, XHHW, USE, OR MV-90*					Size kcmil
	Total per Phase Ampere Rating					
	RHO EARTH 60 LF 50	RHO EARTH 90 LF 100	RHO EARTH 120 LF 100

# Informative Annex

## Conduit and Tubing Fill Tables for Conductors and Fixture Wires of the Same Size

*This informative annex is not a part of the requirements of this NFPA document but is included for informational purposes only.*

### Contents

Table C.1	Maximum Number of Conductors or Fixture Wires in Electrical Metallic Tubing (EMT) <i>(Based on Table 1, Chapter 9)</i>
Table C.1(A)	Maximum Number of Compact Conductors in Electrical Metallic Tubing (EMT) <i>(Based on Table 1, Chapter 9)</i>
Table C.2	Maximum Number of Conductors or Fixture Wires in Electrical Nonmetallic Tubing (ENT) <i>(Based on Table 1, Chapter 9)</i>
Table C.2(A)	Maximum Number of Compact Conductors in Electrical Nonmetallic Tubing (ENT) <i>(Based on Table 1, Chapter 9)</i>
Table C.3	Maximum Number of Conductors or Fixture Wires in Flexible Metal Conduit (FMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.3(A)	Maximum Number of Compact Conductors in Flexible Metal Conduit (FMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.4	Maximum Number of Conductors or Fixture Wires in Intermediate Metal Conduit (IMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.4(A)	Maximum Number of Compact Conductors in Intermediate Metal Conduit (IMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.5	Maximum Number of Conductors or

	Fixture Wires in Liquidtight Flexible Nonmetallic Conduit (Type LFNC-B) <i>(Based on Table 1, Chapter 9)</i>
Table C.5(A)	Maximum Number of Compact Conductors in Liquidtight Flexible Nonmetallic Conduit (Type LFNC-B) <i>(Based on Table 1, Chapter 9)</i>
Table C.6	Maximum Number of Conductors or Fixture Wires in Liquidtight Flexible Nonmetallic Conduit (Type LFNC-A) <i>(Based on Table 1, Chapter 9)</i>
Table C.6(A)	Maximum Number of Compact Conductors in Liquidtight Flexible Nonmetallic Conduit (Type LFNC-A) <i>(Based on Table 1, Chapter 9)</i>
Table C.7	Maximum Number of Conductors or Fixture Wires in Liquidtight Flexible Metal Conduit (LFMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.7(A)	Maximum Number of Compact Conductors in Liquidtight Flexible Metal Conduit (LFMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.8	Maximum Number of Conductors or Fixture Wires in Rigid Metal Conduit (RMC) <i>(Based on Table 1, Chapter 9)</i>
Table C.8(A)	Maximum Number of Compact Conductors in Rigid Metal Conduit (RMC) <i>(Based on Table 1, Chapter 9)</i>

Table C.9	Maximum Number of Conductors or Fixture Wires in Rigid PVC Conduit, Schedule 80 <i>(Based on Table 1, Chapter 9)</i>
Table C.9(A)	Maximum Number of Compact Conductors in Rigid PVC Conduit, Schedule 80 <i>(Based on Table 1, Chapter 9)</i>
Table C.10	Maximum Number of Conductors or Fixture Wires in Rigid PVC Conduit, Schedule 40 and HDPE Conduit <i>(Based on Table 1, Chapter 9)</i>
Table C.10(A)	Maximum Number of Compact Conductors in Rigid PVC Conduit, Schedule 40 and HDPE Conduit <i>(Based on Table 1, Chapter 9)</i>
Table C.11	Maximum Number of Conductors or Fixture Wires in Type A, Rigid PVC Conduit <i>(Based on Table 1, Chapter 9)</i>
Table C.11(A)	Maximum Number of Compact Conductors in Type A, Rigid PVC Conduit <i>(Based on Table 1, Chapter 9)</i>
Table C.12	Maximum Number of Conductors in Type EB, PVC Conduit <i>(Based on Table 1, Chapter 9)</i>
Table C.12(A)	Maximum Number of Compact Conductors in Type EB, PVC Conduit <i>(Based on Table 1, Chapter 9)</i>

Table	Page
C.10(A)* — Rigid PVC Conduit, Schedule 40 and HDPE Conduit	1402
C.11 — Type A, Rigid PVC Conduit	1403
C.11(A)* — Type A, Rigid PVC Conduit	1407
C.12 — Type EB, PVC Conduit	1408
C.12(A)* — Type EB, PVC Conduit	1411

\*Where this table is used in conjunction with Tables C.1 through C.12, the conductors installed must be of the compact type.

The Informative Annex C conduit and tubing conductor fill tables are provided only as an informational tool and are not part of the mandatory requirements of the *Code*. The conductor fill values specified in the Informative Annex C tables have been calculated based on the conductor fill requirements, conduit and tubing dimensions, and conductor dimensions from Chapter 9, Tables 1, 4, 5, and 5A. As such, where the conductors in conduit or tubing are all of the same physical size and insulation characteristic, the use of the Informative Annex C tables to determine the maximum number of conductors ensures compliance with the *Code* requirements for raceway fill found in 300.17 and the respective conduit and tubing articles. For that reason, *NEC* users rely on the widely used and referred-to tables in Informative Annex C as though they were part of the mandatory requirements of the *Code*. Although the values for maximum conduit or tubing fill do not exceed those permitted by Chapter 9, Table 1, the advice provided in Informational Note No.1 to Table 1 on considering a lesser conductor fill or a larger size conduit to that table should always be considered where the wire-pulling conditions are not optimum.

Chapter 9, Table 1, sets forth the percentage fill required, and Tables 4, 5, and 5A list the accurate conduit, tubing, and wire dimensions. Users can calculate the percent fill or use the tables in Informative Annex C, all of which were generated using Chapter 9, Tables 1, 4, 5, and 5A.

The 12 sets of tables in Informative Annex C correspond to the 12 conduit and tubing wiring methods in Chapter 3 of the *Code*. Each set of tables is subdivided into three conductor categories: (1) conductors for general wiring (Article 310); (2) fixture wires (Article 402); and (3) compact stranded conductors (Article 310). In Informative Annex C, tables that use compact stranding are listed as “A” tables.

To select the correct metric designator or trade size conduit or tubing, proceed as follows:

**STEP 1.** Select the appropriate wiring method from Tables C.1 through C.12, using the lists of metallic and nonmetallic wiring methods given in Commentary Tables C.1 and C.2.

Table	Page
C.1 — Electrical Metallic Tubing (EMT)	1353
C.1(A)* — Electrical Metallic Tubing (EMT)	1357
C.2 — Electrical Nonmetallic Tubing (ENT)	1358
C.2(A)* — Electrical Nonmetallic Tubing (ENT)	1362
C.3 — Flexible Metal Conduit (FMC)	1363
C.3(A)* — Flexible Metal Conduit (FMC)	1367
C.4 — Intermediate Metal Conduit (IMC)	1368
C.4(A)* — Intermediate Metal Conduit (IMC)	1372
C.5 — Liquidtight Flexible Nonmetallic Conduit (Type LFNC-B)	1373
C.5(A)* — Liquidtight Flexible Nonmetallic Conduit (Type LFNC-B)	1377
C.6 — Liquidtight Flexible Nonmetallic Conduit (Type LFNC-A)	1378
C.6(A)* — Liquidtight Flexible Nonmetallic Conduit (Type LFNC-A)	1382
C.7 — Liquidtight Flexible Metal Conduit (LFMC)	1383
C.7(A)* — Liquidtight Flexible Metal Conduit (LFMC)	1387
C.8 — Rigid Metal Conduit (RMC)	1388
C.8(A)* — Rigid Metal Conduit (RMC)	1392
C.9 — Rigid PVC Conduit, Schedule 80	1393
C.9(A)* — Rigid PVC Conduit, Schedule 80	1397
C.10 — Rigid PVC Conduit, Schedule 40 and HDPE Conduit	1398

**COMMENTARY TABLE C.1** Metallic Wiring Methods

Type of Wiring	Appropriate Table
Electrical metallic tubing	Table C.1
Flexible metal conduit	Table C.3
Intermediate metal conduit	Table C.4
Liquidtight flexible metal conduit	Table C.7
Rigid metal conduit	Table C.8

**COMMENTARY TABLE C.2** Nonmetallic Wiring Methods

Type of Wiring	Appropriate Table
Electrical nonmetallic tubing	Table C.2
Liquidtight flexible nonmetallic conduit (LFNC-B)	Table C.5
Liquidtight flexible nonmetallic conduit (LFNC-A)	Table C.6
Rigid PVC conduit, Schedule 80	Table C.9
Rigid PVC conduit, Schedule 40 and HDPE conduit	Table C.10
Type A, Rigid PVC conduit	Table C.11
Type EB, PVC conduit	Table C.12

STEP 2. Choose the appropriate conductors (general wiring conductors, fixture wires, or compact conductors).

STEP 3. Choose the appropriate insulation.

STEP 4. Select the correct trade size conduit or tubing for the given quantity and size of conductors required.

The following examples show how to determine the correct trade size conduit or tubing.

#### Application Example 1

An installation requires ten 10 AWG THWN-2 copper conductors in an underground conduit across a parking lot for exterior lighting. What size PVC conduit will be required?

#### Solution

Informative Annex C lists the types of PVC conduit as given in Commentary Table C.3.

**COMMENTARY TABLE C.3** Types of PVC Conduit

Wiring Method	Table	Minimum Trade Size PVC Conduit
Rigid PVC Conduit Schedule 40 and HDPE	Table C.10	1
Type A, Rigid PVC Conduit	Table C.11	¾
Rigid PVC Conduit Schedule 80	Table C.9	1
Type EB, PVC Conduit Type EB	Table C.12	Available only in trade sizes 2 and larger

#### Application Example 2

An underground service lateral requires four 600-kcmil XHHW compact-stranded aluminum conductors. What trade size conduit will be required for RMC, IMC, PVC Schedule 40, PVC Schedule 80, and PVC Type EB?

#### Solution

As given in Commentary Table C.4, Informative Annex C identifies the minimum trade size for the respective conduit types needed for the four 600-kcmil aluminum conductors.

**COMMENTARY TABLE C.4** Minimum Trade Size Conduit

Wiring Method	Table	Minimum Trade Size Conduit
RMC	Table C.8A	3
IMC	Table C.4A	3
Rigid PVC Conduit Schedule 40	Table C.10A	3
Rigid PVC Conduit Schedule 80	Table C.9A	3½
Type EB PVC Conduit	Table C.12A	3

Most aluminum building wire in Types THW, THWN/THHN, and XHHW is compact stranded.

#### Application Example 3

A 3-phase, 480-volt, 40-hp motor will be supplied by three 4 AWG THW conductors. What size metal conduit or tubing will be required? What size metal flex will be required at the motor termination?

#### Solution

Informative Annex C lists various types of metal conduit and metal flex as shown in Commentary Table C.5.

**COMMENTARY TABLE C.5** Types of Metal Conduit and Metal Flex

Wiring Method	Table	Trade Size Conduit or Tubing
EMT	Table C.1	1
IMC	Table C.4	1
RMC	Table C.8	1
FMC	Table C.3	1
Liquidtight FMC	Table C.7	1

If a wire-type equipment grounding conductor (likely to be smaller than 4 AWG based on rating or size of motor circuit short-circuit, ground-fault protective device, and Table 250.122) is installed in any one of these raceway types, there is now a mixture of conductor sizes. For that reason, the minimum size conduit or tubing has to be calculated based

on Chapter 9, Tables 4, 5, and 8 if a wire-type equipment grounding conductor is installed in the conduit or tubing. Of course, based on the Informative Annex C tables, the conduit size could be increased to trade size 1¼. Because six 4 AWG THW conductors can be installed in trade size 1¼ it would be of sufficient size for the three circuit conductors and the wire-type equipment grounding conductor. According to 250.122(A), a wire-type equipment grounding conductor is not required to be larger than the circuit conductors. This approach may not yield the minimum conduit or tubing size but will result in a compliant installation and may facilitate an easier installation if the conduit run is particu-

larly long or has a substantial amount of bends. See the commentary following Informational Note No. 1 to Chapter 9, Table 1.

#### Application Example 4

A fire alarm system installation requires the riser to contain twenty-one 16 AWG TFF conductors. If the riser conductors are installed in electrical metallic tubing, what minimum size tubing is required?

#### Solution

According to Table C.1, trade size 1 EMT is required.

**TABLE C.1 Maximum Number of Conductors or Fixture Wires in Electrical Metallic Tubing (EMT) (Based on Table 1, Chapter 9)**

## Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.1(A) should be used.
2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

**TABLE C.3 Maximum Number of Conductors or Fixture Wires in Flexible Metal Conduit (FMC) (Based on Table 1, Chapter 9)**

**Notes:**

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.3(A) should be used.
2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.4(A) should be used.
2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.5(A) should be used.

2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Corresponds to 356.2(2).

†Types RHH, RHW, and RHW-2 without outer covering.

\*Corresponds to 356.2(2).

 Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.6(A) should be used.

2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Corresponds to 356.2(1).

†Types RHH, RHW, and RHW-2 without outer covering.

\*Corresponds to 356.2(1).

 Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

## Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.7(A) should be used.
2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.8(A) should be used.

2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

**TABLE C.9 Maximum Number of Conductors or Fixture Wires in Rigid PVC Conduit, Schedule 80** (Based on Table I, Chapter 9)

## Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.9(A) should be used.
2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.10(A) should be used.

2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RHW-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

## Notes:

1. This table is for concentric stranded conductors only. For compact stranded conductors, Table C.11(A) should be used.
2. Two-hour fire-rated RHH cable has ceramifiable insulation which has much larger diameters than other RHH wires. Consult manufacturer's conduit fill tables.

\*Types RHH, RHW, and RWH-2 without outer covering.

Definition: *Compact stranding* is the result of a manufacturing process where the standard conductor is compressed to the extent that the interstices (voids between strand wires) are virtually eliminated.

### Example D13(d) Single Conductor Cables 250 kcmil through 900 kcmil

**Selection of Conductors.** In the following examples, the results are generally expressed in amperes (A). To select conductor sizes, refer to the 0 through 2000 volt (V) ampacity tables of Article 310 and the rules of 310.15 that pertain to these tables.

**Voltage.** For uniform application of Articles 210, 215, and 220, a nominal voltage of 120, 120/240, 240, and 208Y/120 V is used in calculating the ampere load on the conductor.

**Fractions of an Ampere.** Except where the calculations result in a major fraction of an ampere (0.5 or larger), such fractions are permitted to be dropped.

**Power Factor.** Calculations in the following examples are based, for convenience, on the assumption that all loads have the same power factor (PF).

**Ranges.** For the calculation of the range loads in these examples, Column C of Table 220.55 has been used. For optional methods, see Columns A and B of Table 220.55. Except where the calculations result in a major fraction of a kilowatt (0.5 or larger), such fractions are permitted to be dropped.

**SI Units.** For metric conversions,  $0.093 \text{ m}^2 = 1 \text{ ft}^2$  and  $0.3048 \text{ m} = 1 \text{ ft}$ .

In the examples in this informative annex, loads are assumed to be properly balanced on the system. If loads are not properly balanced, additional feeder capacity may be required. The calculations are based on the standard method using Parts I, II, and III of Article 220.

### Example D1(a) One-Family Dwelling

The dwelling has a floor area of 1500 ft<sup>2</sup>, exclusive of an unfinished cellar not adaptable for future use, unfinished attic, and open porches. Appliances are a 12-kW range and a 5.5-kW, 240-V dryer. Assume range and dryer kW ratings equivalent to kVA ratings in accordance with 220.54 and 220.55.

The general lighting and general-use receptacle load is computed from the outside dimensions of the building, apartment, or other area involved. For a dwelling unit, the computed floor area is not to include open porches, garages, or, as stated in the opening paragraph, “an unfinished cellar not adaptable for future use.” A point to consider regarding this statement is that many of today’s homes with basements or cellars do have space that is suitable for conversion to family rooms, bedrooms, home offices, or other habitable areas. In such instances, the basement or cellar space suitable for conversion needs to be included in the general lighting load calculation. See 220.12 and 220.14(J) for requirements on how to calculate the lighting and general-use receptacle load for this occupancy.

The two-story dwelling measures 30 ft × 30 ft for the first floor and 30 ft × 20 ft for the second floor.

$$\begin{aligned}\text{First-floor area: } 30 \text{ ft} \times 30 \text{ ft} &= 900 \text{ ft}^2 \\ \text{Second-floor area: } 30 \text{ ft} \times 20 \text{ ft} &= 600 \text{ ft}^2 \\ \text{Total area} &= 1500 \text{ ft}^2\end{aligned}$$

**Calculated Load** [see 220.40]

**General Lighting Load** 1500 ft<sup>2</sup> at 3 VA/ft<sup>2</sup> = 4500 VA

**Minimum Number of Branch Circuits Required** [see 210.11(A)]

**General Lighting Load:** 4500 VA ÷ 120 V = 38 A

This requires three 15-A, 2-wire or two 20-A, 2-wire circuits.

Small-Appliance Load: Two 2-wire, 20-A circuits [see 210.11(C)(1)]

Laundry Load: One 2-wire, 20-A circuit [see 210.11(C)(2)]

Bathroom Branch Circuit: One 2-wire, 20-A circuit (no additional load calculation is required for this circuit) [see 210.11(C)(3)]

**Minimum Size Feeder Required** [see 220.40]

General Lighting	4,500 VA
Small Appliance	3,000 VA
Laundry	1,500 VA
<b>Total</b>	<b>9,000 VA</b>
3000 VA at 100%	3,000 VA
9000 VA – 3000 VA = 6000 VA at 35%	2,100 VA
<b>Net Load</b>	<b>5,100 VA</b>
Range (see Table 220.55)	8,000 VA
Dryer Load (see Table 220.54)	5,500 VA
<b>Net Calculated Load</b>	<b>18,600 VA</b>

**Net Calculated Load for 120/240-V, 3-wire, single-phase service or feeder**

$$18,600 \text{ VA} \div 240 \text{ V} = 78 \text{ A}$$

Sections 230.42(B) and 230.79 require service conductors and disconnecting means rated not less than 100 amperes.

**Calculation for Neutral for Feeder and Service**

Lighting and Small-Appliance Load	5,100 VA
Range: 8000 VA at 70% (see 220.61)	5,600 VA
Dryer: 5500 VA at 70% (see 220.61)	3,850 VA
<b>Total</b>	<b>14,550 VA</b>

**Calculated Load for Neutral**

$$14,550 \text{ VA} \div 240 \text{ V} = 61 \text{ A}$$

### Example D1(b) One-Family Dwelling

Assume same conditions as Example No. D1(a), plus addition of one 6-A, 230-V, room air-conditioning unit and one 12-A, 115-V, room air-conditioning unit,\* one 8-A, 115-V, rated waste disposer, and one 10-A, 120-V, rated dishwasher. See Article 430 for general motors and Article 440, Part VII, for air-conditioning equipment. Motors have nameplate ratings of 115 V and 230 V for use on 120-V and 240-V nominal voltage systems.

\*(For feeder neutral, use larger of the two appliances for unbalance.)

From Example D1(a), feeder current is 78 A (3-wire, 240 V).

	Line A	Neutral	Line B
Amperes from Example D1(a)	78	61	78
One 230-V air conditioner	6	—	6
One 115-V air conditioner and 120-V dishwasher	12	12	10
One 115-V disposer	—	8	8
25% of largest motor (see 430.24)	3	3	2
<b>Total amperes per conductor</b>	<b>99</b>	<b>84</b>	<b>104</b>

Therefore, the service would be rated 110 A.

The air-conditioning load is calculated at 100 percent and is calculated separately to comply with the requirements of 220.82(C)(1).

### Example D2(a) Optional Calculation for One-Family Dwelling, Heating Larger Than Air Conditioning [see 220.82]

The dwelling has a floor area of 1500 ft<sup>2</sup>, exclusive of an unfinished cellar not adaptable for future use, unfinished attic, and open porches. It has a 12-kW range, a 2.5-kW water heater, a 1.2-kW dishwasher, 9 kW of electric space heating installed in five rooms, a 5-kW clothes dryer, and a 6-A, 230-V, room air-conditioning unit. Assume range, water heater, dishwasher, space heating, and clothes dryer kW ratings equivalent to kVA.

**Air Conditioner kVA Calculation**

$$6 \text{ A} \times 230 \text{ V} \div 1000 = 1.38 \text{ kVA}$$

This 1.38 kVA [item 1 from 220.82(C)] is less than 40% of 9 kVA of separately controlled electric heat [item 6 from 220.82(C)], so the 1.38 kVA need not be included in the service calculation.

**General Load**

1500 ft <sup>2</sup> at 3 VA	4,500 VA
Two 20-A appliance outlet circuits at 1500 VA each	3,000 VA
Laundry circuit	1,500 VA
Range (at nameplate rating)	12,000 VA
Water heater	2,500 VA
Dishwasher	1,200 VA
Clothes dryer	5,000 VA
<b>Total</b>	<b>29,700 VA</b>

**Application of Demand Factor** [see 220.82(B)]

First 10 kVA of general load at 100%	10,000 VA
Remainder of general load at 40% (19.7 kVA × 0.4)	7,880 VA
<b>Total of general load</b>	<b>17,880 VA</b>
9 kVA of heat at 40% (9000 VA × 0.4) =	3,600 VA
<b>Total</b>	<b>21,480 VA</b>

#### Calculated Load for Service Size

$$21.48 \text{ kVA} = 21,480 \text{ VA}$$

$$21,480 \text{ VA} \div 240 \text{ V} = 90 \text{ A}$$

Therefore, the minimum service rating would be 100 A in accordance with 230.42 and 230.79.

#### Feeder Neutral Load in Accordance with 220.61

1500 ft <sup>2</sup> at 3 VA	4,500 VA
Three 20-A circuits at 1500 VA	4,500 VA
Total	9,000 VA
3000 VA at 100%	3,000 VA
9000 VA — 3000 VA = 6000 VA at 35%	2,100 VA
Subtotal	5,100 VA
Range: 8 kVA at 70%	5,600 VA
Clothes dryer: 5 kVA at 70%	3,500 VA
Dishwasher	1,200 VA
Total	15,400 VA

#### Calculated Load for Neutral

$$15,400 \text{ VA} \div 240 \text{ V} = 64 \text{ A}$$

#### Example D2(b) Optional Calculation for One-Family Dwelling, Air Conditioning Larger Than Heating

[see 220.82(A) and 220.82(C)]

The dwelling has a floor area of 1500 ft<sup>2</sup>, exclusive of an unfinished cellar not adaptable for future use, unfinished attic, and open porches. It has two 20-A small appliance circuits, one 20-A laundry circuit, two 4-kW wall-mounted ovens, one 5.1-kW counter-mounted cooking unit, a 4.5-kW water heater, a 1.2-kW dishwasher, a 5-kW combination clothes washer and dryer, six 7-A, 230-V room air-conditioning units, and a 1.5-kW permanently installed bathroom space heater. Assume wall-mounted ovens, counter-mounted cooking unit, water heater, dishwasher, and combination clothes washer and dryer kW ratings equivalent to kVA.

#### Air Conditioning kVA Calculation

$$\text{Total amperes} = 6 \text{ units} \times 7 \text{ A} = 42 \text{ A}$$

$$42 \text{ A} \times 240 \text{ V} \div 1000 = 10.08 \text{ kVA (assume PF} = 1.0)$$

#### Load Included at 100%

**Air Conditioning:** Included below [see item 1 in 220.82(C)]

**Space Heater:** Omit [see item 5 in 220.82(C)]

#### General Load

1500 ft <sup>2</sup> at 3 VA	4,500 VA
Two 20-A small-appliance circuits at 1500 VA each	3,000 VA
Laundry circuit	1,500 VA
Two ovens	8,000 VA
One cooking unit	5,100 VA
Water heater	4,500 VA
Dishwasher	1,200 VA
Washer/dryer	5,000 VA
Total general load	32,800 VA
First 10 kVA at 100%	10,000 VA
Remainder at 40% (22.8 kVA $\times$ 0.4 $\times$ 1000)	9,120 VA
Subtotal general load	19,120 VA
Air conditioning	10,080 VA
Total	29,200 VA

#### Calculated Load for Service

$$29,200 \text{ VA} \div 240 \text{ V} = 122 \text{ A (service rating)}$$

#### Feeder Neutral Load, in accordance with 220.61

Assume that the two 4-kVA wall-mounted ovens are supplied by one branch circuit, the 5.1-kVA counter-mounted cooking unit by a separate circuit.

1500 ft <sup>2</sup> at 3 VA	4,500 VA
Three 20-A circuits at 1500 VA	4,500 VA
Subtotal	9,000 VA
3000 VA at 100%	3,000 VA
9000 VA — 3000 VA = 6000 VA at 35%	2,100 VA
Subtotal	5,100 VA
Two 4-kVA ovens plus one 5.1-kVA cooking unit = 13.1 kVA. Table 220.55 permits 55% demand factor or 13.1 kVA $\times$ 0.55 = 7.2 kVA feeder capacity.	
Subtotal from above	5,100 VA
Ovens and cooking unit: 7200 VA $\times$ 70% for neutral load	5,040 VA
Clothes washer/dryer: 5 kVA $\times$ 70% for neutral load	3,500 VA
Dishwasher	1,200 VA
Total	14,840 VA

#### Calculated Load for Neutral

$$14,840 \text{ VA} \div 240 \text{ V} = 62$$

#### Example D2(c) Optional Calculation for One-Family Dwelling with Heat Pump (Single-Phase, 240/120-Volt Service) (see 220.82)

The dwelling has a floor area of 2000 ft<sup>2</sup>, exclusive of an unfinished cellar not adaptable for future use, unfinished attic, and open porches. It has a 12-kW range, a 4.5-kW water heater, a 1.2-kW dishwasher, a 5-kW clothes dryer, and a 2½-ton (24-A) heat pump with 15 kW of backup heat.

#### Heat Pump kVA Calculation

$$24 \text{ A} \times 240 \text{ V} \div 1000 = 5.76 \text{ kVA}$$

This 5.76 kVA is less than 15 kVA of the backup heat; therefore, the heat pump load need not be included in the service calculation [see 220.82(C)]

#### General Load

2000 ft <sup>2</sup> at 3 VA	6,000 VA
Two 20-A appliance outlet circuits at 1500 VA each	3,000 VA
Laundry circuit	1,500 VA
Range (at nameplate rating)	12,000 VA
Water heater	4,500 VA
Dishwasher	1,200 VA
Clothes dryer	5,000 VA
Subtotal general load	33,200 VA
First 10 kVA at 100%	10,000 VA
Remainder of general load at 40% (23,200 VA $\times$ 0.4)	9,280 VA
Total net general load	19,280 VA

#### Heat Pump and Supplementary Heat\*

$$240 \text{ V} \times 24 \text{ A} = 5760 \text{ VA}$$

#### 15 kW Electric Heat:

$$5760 \text{ VA} + (15,000 \text{ VA} \times 65\%) = 5.76 \text{ kVA} + 9.75 \text{ kVA} = 15.51 \text{ kVA}$$

\*If supplementary heat is not on at same time as heat pump, heat pump kVA need not be added to total.

### Totals

Net general load	19,280 VA
Heat pump and supplementary heat	15,510 VA
Total	34,790 VA

### Calculated Load for Service

$$34.79 \text{ kVA} \times 1000 \div 240 \text{ V} = 145 \text{ A}$$

Therefore, this dwelling unit would be permitted to be served by a 150-A service.

### Example D3 Store Building

A store 50 ft by 60 ft, or 3000 ft<sup>2</sup>, has 30 ft of show window. There are a total of 80 duplex receptacles. The service is 120/240 V, single phase 3-wire service. Actual connected lighting load is 8500 VA.

### Calculated Load (see 220.40)

#### Noncontinuous Loads

Receptacle Load (see 220.44)

80 receptacles at 180 VA	14,400 VA
10,000 VA at 100%	10,000 VA
14,400 VA – 10,000 VA = 4400 at 50%	2,200 VA
Subtotal	12,200 VA

#### Continuous Loads

General Lighting\*

3000 ft <sup>2</sup> at 3 VA/ft <sup>2</sup>	9,000 VA
--	----------

Show Window Lighting Load

30 ft at 200 VA/ft [see 220.14(G)]	6,000 VA
------------------------------------	----------

Outside Sign Circuit [see 220.14(F)]	1,200 VA
--------------------------------------	----------

Subtotal	16,200 VA
----------	-----------

Subtotal from noncontinuous	12,200 VA
-----------------------------	-----------

Total noncontinuous loads + continuous loads =	28,400 VA
--	-----------

\*In the example, 125% of the actual connected lighting load (8500 VA  $\times$  1.25 = 10,625 VA) is less than 125% of the load from Table 220.12, so the minimum lighting load from Table 220.12 is used in the calculation. Had the actual lighting load been greater than the value calculated from Table 220.12, 125% of the actual connected lighting load would have been used.

### Minimum Number of Branch Circuits Required

General Lighting: Branch circuits need only be installed to supply the actual connected load [see 210.11(B)].

$$8500 \text{ VA} \times 1.25 = 10,625 \text{ VA}$$

$$10,625 \text{ VA} \div 240 \text{ V} = 44 \text{ A for 3-wire, 120/240 V}$$

The lighting load would be permitted to be served by 2-wire or 3-wire, 15- or 20-A circuits with combined capacity equal to 44 A or greater for 3-wire circuits or 88 A or greater for 2-wire circuits. The feeder capacity as well as the number of branch-circuit positions available for lighting circuits in the panelboard must reflect the full calculated load of  $9000 \text{ VA} \times 1.25 = 11,250 \text{ VA}$ .

### Show Window

$$6000 \text{ VA} \times 1.25 = 7500 \text{ VA}$$

$$7500 \text{ VA} \div 240 \text{ V} = 31 \text{ A for 3-wire, 120/240 V}$$

The show window lighting is permitted to be served by 2-wire or 3-wire circuits with a capacity equal to 31 A or greater for 3-wire circuits or 62 A or greater for 2-wire circuits.

Receptacles required by 210.62 are assumed to be included in the receptacle load above if these receptacles do not supply the show window lighting load.

### Receptacles

Receptacle Load:  $14,400 \text{ VA} \div 240 \text{ V} = 60 \text{ A}$  for 3-wire, 120/240 V

The receptacle load would be permitted to be served by 2-wire or 3-wire circuits with a capacity equal to 60 A or greater for 3-wire circuits or 120 A or greater for 2-wire circuits.

### Minimum Size Feeder (or Service) Overcurrent Protection

[see 215.3 or 230.90]

Subtotal noncontinuous loads	12,200 VA
------------------------------	-----------

Subtotal continuous load at 125% ( $16,200 \text{ VA} \times 1.25$ )	20,250 VA
--	-----------

Total	32,450 VA
-------	-----------

$$32,450 \text{ VA} \div 240 \text{ V} = 135 \text{ A}$$

The next higher standard size is 150 A (see 240.6).

### Minimum Size Feeders (or Service Conductors) Required [see 215.2, 230.42(A)]

For 120/240 V, 3-wire system,

$$32,450 \text{ VA} \div 240 \text{ V} = 135 \text{ A}$$

Service or feeder conductor is 1/0 Cu in accordance with 215.3 and Table 310.15(B)(16) (with 75°C terminations).

### Example D3(a) Industrial Feeders in a Common Raceway

An industrial multi-building facility has its service at the rear of its main building, and then provides 480Y/277-volt feeders to additional buildings behind the main building in order to segregate certain processes. The facility supplies its remote buildings through a partially enclosed access corridor that extends from the main switchboard rearward along a path that provides convenient access to services within 15 m (50 ft) of each additional building supplied. Two building feeders share a common raceway for approximately 45 m (150 ft) and run in the access corridor along with process steam and control and communications cabling. The steam raises the ambient temperature around the power raceway to as much as 35°C. At a tee fitting, the individual building feeders then run to each of the two buildings involved. The feeder neutrals are not connected to the equipment grounding conductors in the remote buildings. All distribution equipment terminations are listed as being suitable for 75°C connections.

Each of the two buildings has the following loads:

Lighting, 11,600 VA, comprised of electric-discharge luminaires connected at 277 V

Receptacles, 22 125-volt, 20-ampere receptacles on general-purpose branch circuits, supplied by separately derived systems in each of the buildings

1 Air compressor, 460 volt, three phase, 7.5 hp

1 Grinder, 460 volt, three phase, 1.5 hp

3 Welders, AC transformer type (nameplate: 23 amperes, 480 volts, 60 percent duty cycle)

3 Industrial Process Dryers, 480 volt, three phase, 15 kW each (assume continuous use throughout certain shifts)

Determine the overcurrent protection and conductor size for the feeders in the common raceway, assuming the use of XHHW-2 insulation (90°C):

**Calculated Load** {Note: For reasonable precision, volt-ampere calculations are carried to three significant figures only; where loads are converted to amperes, the results are rounded to the nearest ampere [see 220.5(B)]}.

### Noncontinuous Loads

Receptacle Load (see 220.44 )

22 receptacles at 180 VA	3,960 VA
--------------------------	----------

Welder Load [see 630.11(A), Table 630.11(A)]

$$\text{Each welder: } 480 \text{ V} \times 23 \text{ A} \times 0.78 = 8,610 \text{ VA}$$

All 3 welders: [see 630.11(B)] (demand factors 100%, 100%, 85% respectively)	
8,610 VA + 8,610 VA + 7,320 VA =	24,500 VA
<b>Subtotal, Noncontinuous Loads</b>	<b>28,500 VA</b>
<b>Motor Loads (see 430.24, Table 430.250)</b>	
Air compressor: $11 \text{ A} \times 480 \text{ V} \times \sqrt{3} =$	9,150 VA
Grinder: $3 \text{ A} \times 480 \text{ V} \times \sqrt{3} =$	2,490 VA
Largest motor, additional 25%:	2,290 VA
<b>Subtotal, Motor Loads</b>	<b>13,900 VA</b>
By using 430.24, the motor loads and the noncontinuous loads can be combined for the remaining calculation.	
<b>Subtotal for load calculations, Noncontinuous Loads</b>	<b>42,400 VA</b>
<b>Continuous Loads</b>	
General Lighting	11,600 VA
3 Industrial Process Dryers 15 kW each	45,000 VA
<b>Subtotal, Continuous Loads:</b>	<b>56,600 VA</b>
<b>Overcurrent protection (see 215.3)</b>	
The overcurrent protective device must accommodate 125% of the continuous load, plus the noncontinuous load:	
Continuous load	56,600 VA
Noncontinuous load	42,400 VA
<b>Subtotal, actual load [actual load in amperes]</b>	
$[99,000 \text{ VA} \div (480 \text{ V} \times \sqrt{3}) = 119 \text{ A}]$	<b>99,000 VA</b>
(25% of 56,600 VA) (See 215.3)	<b>14,200 VA</b>
<b>Total VA</b>	<b>113,200 VA</b>
Conversion to amperes using three significant figures:	
$113,200 \text{ VA} \div (480 \text{ V} \times \sqrt{3}) = 136 \text{ A}$	
Minimum size overcurrent protective device: 136 A	
Minimum standard size overcurrent protective device (see 240.6): 150 amperes	

Where the overcurrent protective device and its assembly are listed for operation at 100 percent of its rating, a 125 ampere overcurrent protective device would be permitted. However, overcurrent protective device assemblies listed for 100 percent of their rating are typically not available at the 125-ampere rating. (See 215.3 Exception.)

#### Ungrounded Feeder Conductors

The conductors must independently meet requirements for (1) terminations, and (2) conditions of use throughout the raceway run.

Minimum size conductor at the overcurrent device termination [see 110.14(C) and 215.2(A)(1), using 75°C ampacity column in Table 310.15(B)(16)]: 1/0 AWG.

Minimum size conductors in the raceway based on actual load [see Article 100, Ampacity, and 310.15(B)(3)(a) and correction factors to Table 310.15(B)(16)]:

$$99,000 \text{ VA} \div 0.7 \div 0.96 = 147,000 \text{ VA}$$

$[70\% = 310.15(B)(3)(a)]$  &  $[0.96 = \text{Correction factors to Table 310.15(B)(16)}]$

Conversion to amperes:

$$147,000 \text{ VA} \div (480 \text{ V} \times \sqrt{3}) = 177 \text{ A}$$

Note that the neutral conductors are counted as current-carrying conductors [see 310.15(B)(5)(c)] in this example because the discharge lighting has substantial nonlinear content. This requires a 2/0 AWG conductor based on the 90°C column of Table 310.15(B)(16). Therefore, the worst case is given by the raceway conditions, and 2/0 AWG conductors must be used. If the utility corridor was at normal temperatures  $[(30^\circ\text{C} (86^\circ\text{F}))]$ , and if the lighting at each building were supplied from the local separately de-

rived system (thus requiring no neutrals in the supply feeders) the raceway result  $(99,000 \text{ VA} \div 0.8 = 124,000 \text{ VA}; 124,000 \text{ VA} \div (480 \text{ V} \times \sqrt{3}) = 149 \text{ A}$ , or a 1 AWG conductor @90°C) could not be used because the termination result (1/0 AWG based on the 75°C column of Table 310.15(B)(16)) would become the worst case, requiring the larger conductor.

In every case, the overcurrent protective device shall provide overcurrent protection for the feeder conductors in accordance with their ampacity as provided by this Code (see 240.4). A 90°C 2/0 AWG conductor has a Table 310.15(B)(16) ampacity of 195 amperes. Adjusting for the conditions of use (35°C ambient temperature, 8 current-carrying conductors in the common raceway),

$$195 \text{ amperes} \times 0.96 \times 0.7 = 131 \text{ A}$$

The 150-ampere circuit breaker protects the 2/0 AWG feeder conductors, because 240.4(B) permits the use of the next higher standard size overcurrent protective device. Note that the feeder layout precludes the application of 310.15(A)(2) Exception.

#### Feeder Neutral Conductor (see 220.61)

Because 210.11(B) does not apply to these buildings, the load cannot be assumed to be evenly distributed across phases. Therefore the maximum imbalance must be assumed to be the full lighting load in this case, or 11,600 VA.  $(11,600 \text{ VA} \div 277 \text{ V} = 42 \text{ amperes})$ . The ability of the neutral to return fault current [see 250.32(B) Exception(2)] is not a factor in this calculation.

Because the neutral runs between the main switchboard and the building panelboard, likely terminating on a busbar at both locations, and not on overcurrent devices, the effects of continuous loading can be disregarded in evaluating its terminations [see 215.2(A)(1) Exception No. 2]. That calculation is  $(11,600 \text{ VA} \div 277 \text{ V}) = 42 \text{ amperes}$ , to be evaluated under the 75°C column of Table 310.15(B)(16). The minimum size of the neutral might seem to be 8 AWG, but that size would not be sufficient to be depended upon in the event of a line-to-neutral short circuit [see 215.2(A)(1), second paragraph]. Therefore, since the minimum size equipment grounding conductor for a 150 ampere circuit, as covered in Table 250.122, is 6 AWG, that is the minimum neutral size required for this feeder.

### Example D4(a) Multifamily Dwelling

A multifamily dwelling has 40 dwelling units.

Meters are in two banks of 20 each with individual feeders to each dwelling unit.

One-half of the dwelling units are equipped with electric ranges not exceeding 12 kW each. Assume range kW rating equivalent to kVA rating in accordance with 220.55. Other half of ranges are gas ranges.

Area of each dwelling unit is 840 ft<sup>2</sup>.

Laundry facilities on premises are available to all tenants. Add no circuit to individual dwelling unit.

#### Calculated Load for Each Dwelling Unit (see Article 220)

General Lighting: 840 ft<sup>2</sup> at 3 VA/ft<sup>2</sup> = 2520 VA

Special Appliance: Electric range (see 220.55) = 8000 VA

#### Minimum Number of Branch Circuits Required for Each Dwelling Unit [see 210.11(A)]

General Lighting Load:  $2520 \text{ VA} \div 120 \text{ V} = 21 \text{ A}$  or two 15-A, 2-wire circuits; or two 20-A, 2-wire circuits

Small-Appliance Load: Two 2-wire circuits of 12 AWG wire [see 210.11(C)(1)]

Range Circuit:  $8000 \text{ VA} \div 240 \text{ V} = 33 \text{ A}$  or a circuit of two 8 AWG conductors and one 10 AWG conductor in accordance with 210.19(A)(3)

#### Minimum Size Feeder Required for Each Dwelling Unit (see 215.2)

Calculated Load (see Article 220):

General Lighting	2,520 VA
Small Appliance (two 20-ampere circuits)	3,000 VA
Subtotal Calculated Load (without ranges)	5,520 VA

#### Application of Demand Factor (see Table 220.42)

First 3000 VA at 100%	3,000 VA
5520 VA — 3000 VA = 2520 VA at 35%	882 VA
Net Calculated Load (without ranges)	3,882 VA
Range Load	8,000 VA
Net Calculated Load (with ranges)	11,882 VA

#### Size of Each Feeder (see 215.2)

For 120/240-V, 3-wire system (without ranges)	
Net calculated load of 3882 VA ÷ 240 V = 16 A	
For 120/240-V, 3-wire system (with ranges)	
Net calculated load, 11,882 VA ÷ 240 V = 50 A	

#### Feeder Neutral

Lighting and Small-Appliance Load	3,882 VA
Range Load: 8000 VA at 70% (see 220.61)	5,600 VA
(only for apartments with electric range)	5,600 VA
Net Calculated Load (neutral)	9,482 VA

#### Calculated Load for Neutral

$$9482 \text{ VA} \div 240 \text{ V} = 39.5 \text{ A}$$

#### Minimum Size Feeders Required from Service Equipment to Meter Bank (For 20 Dwelling Units — 10 with Ranges)

Total Calculated Load:

Lighting and Small Appliance	
20 units × 5520 VA	110,400 VA
Application of Demand Factor	
First 3000 VA at 100%	3,000 VA
110,400 VA — 3000 VA = 107,400 VA at 35%	37,590 VA
Net Calculated Load	40,590 VA
Range Load: 10 ranges (not over 12 kVA)	
(see Col. C, Table 220.55, 25 kW)	25,000 VA
Net Calculated Load (with ranges)	65,590 VA
Net calculated load for 120/240-V, 3-wire system,	
65,590 VA ÷ 240 V = 273 A	

#### Feeder Neutral

Lighting and Small-Appliance Load	40,590 VA
Range Load: 25,000 VA at 70% [see 220.61(B)]	17,500 VA
Calculated Load (neutral)	58,090 VA

#### Calculated Load for Neutral

$$58,090 \text{ VA} \div 240 \text{ V} = 242 \text{ A}$$

#### Further Demand Factor [220.61(B)]

200 A at 100%	200 A
242 A — 200 A = 42 A at 70%	29 A
Net Calculated Load (neutral)	229 A

#### Minimum Size Main Feeders (or Service Conductors) Required (Less House Load) (For 40 Dwelling Units — 20 with Ranges)

Total Calculated Load:	
Lighting and Small-Appliance Load	
40 units × 5520 VA	220,800 VA

#### Application of Demand Factor (from Table 220.42)

First 3000 VA at 100%	3,000 VA
Next 120,000 VA — 3000 VA = 117,000 VA at 35%	40,950 VA
Remainder 220,800 VA — 120,000 VA = 100,800 VA at 25%	25,200 VA
Net Calculated Load	69,150 VA
Range Load: 20 ranges (less than 12 kVA)	
(see Col. C, Table 220.55)	35,000 VA
Net Calculated Load	104,150 VA

For 120/240-V, 3-wire system

$$\text{Net calculated load of } 104,150 \text{ VA} \div 240 \text{ V} = 434 \text{ A}$$

#### Feeder Neutral

Lighting and Small-Appliance Load	69,150 VA
Range: 35,000 VA at 70% [see 220.61(B)]	24,500 VA
Calculated Load (neutral)	93,650 VA
93,650 VA ÷ 240 V = 390 A	

#### Further Demand Factor [see 220.61(B)]

200 A at 100%	200 A
390 A — 200 A = 190 A at 70%	133 A
Net Calculated Load (neutral)	333 A

[See Table 310.15(B)(16) through Table 310.15(B)(21), and 310.15(B)(2), (B)(3), and (B)(5).]

#### Example D4(b) Optional Calculation for Multifamily Dwelling

A multifamily dwelling equipped with electric cooking and space heating or air conditioning has 40 dwelling units.

Meters are in two banks of 20 each plus house metering and individual feeders to each dwelling unit.

Each dwelling unit is equipped with an electric range of 8-kW nameplate rating, four 1.5-kW separately controlled 240-V electric space heaters, and a 2.5-kW, 240-V electric water heater. Assume range, space heater, and water heater kW ratings equivalent to kVA.

A common laundry facility is available to all tenants [see 210.52(F), Exception No. 1].

Area of each dwelling unit is 840 ft<sup>2</sup>.

#### Calculated Load for Each Dwelling Unit (see Article 220)

General Lighting Load:	
840 ft <sup>2</sup> at 3 VA/ft <sup>2</sup>	2,520 VA
Electric range	8,000 VA
Electric heat: 6 kVA (or air conditioning if larger)	6,000 VA
Electric water heater	2,500 VA

#### Minimum Number of Branch Circuits Required for Each Dwelling Unit

General Lighting Load: 2520 VA ÷ 120 V = 21 A or two 15-A, 2-wire circuits, or two 20-A, 2-wire circuits

Small-Appliance Load: Two 2-wire circuits of 12 AWG [see 210.11(C)(1)]

Range Circuit (See Table 220.55, Column B):

$$8000 \text{ VA} \times 80\% \div 240 \text{ V} = 27 \text{ A on a circuit of three } 10 \text{ AWG conductors in accordance with } 210.19(\text{A})(3)$$

Space Heating: 6000 VA ÷ 240 V = 25 A

Number of circuits (see 210.11)

#### Minimum Size Feeder Required for Each Dwelling Unit (see 215.2)

Calculated Load (see Article 220):	
General Lighting	2,520 VA
Small Appliance (two 20-A circuits)	3,000 VA
Subtotal Calculated Load (without range and space heating)	5,520 VA

### Application of Demand Factor

First 3000 VA at 100%	3,000 VA
5520 VA – 3000 VA = 2520 VA at 35%	882 VA
Net Calculated Load (without range and space heating)	3,882 VA
Range	6,400 VA
Space Heating ( <i>see</i> 220.51)	6,000 VA
Water Heater	2,500 VA
Net Calculated Load (for individual dwelling unit)	18,782 VA

### Size of Each Feeder

For 120/240-V, 3-wire system,  
Net calculated load of 18,782 VA ÷ 240 V = 78 A

### Feeder Neutral (*see* 220.61)

Lighting and Small Appliance	3,882 VA
Range Load: 6400 VA at 70% [ <i>see</i> 220.61(B)]	4,480 VA
Space and Water Heating (no neutral): 240 V	0 VA
Net Calculated Load (neutral)	8,362 VA

### Calculated Load for Neutral

8362 VA ÷ 240 V = 35 A

### Minimum Size Feeder Required from Service Equipment to Meter Bank (For 20 Dwelling Units)

Total Calculated Load:	
Lighting and Small-Appliance Load	
20 units × 5520 VA	110,400 VA
Water and Space Heating Load	
20 units × 8500 VA	170,000 VA
Range Load: 20 × 8000 VA	160,000 VA
Net Calculated Load (20 dwelling units)	440,400 VA
Net Calculated Load Using Optional Calculation ( <i>see</i> Table 220.84)	
440,400 VA × 0.38	167,352 VA
167,352 VA ÷ 240 V = 697 A	

### Minimum Size Main Feeder Required (Less House Load) (For 40 Dwelling Units)

Calculated Load:	
Lighting and Small-Appliance Load	
40 units × 5520 VA	220,800 VA
Water and Space Heating Load	
40 units × 8500 VA	340,000 VA
Range: 40 ranges × 8000 VA	320,000 VA
Net Calculated Load (40 dwelling units)	880,800 VA
Net Calculated Load Using Optional Calculation ( <i>see</i> Table 220.84)	
880,800 VA × 0.28 = 246,624 VA	
246,624 VA ÷ 240 V = 1028 A	

### Feeder Neutral Load for Feeder from Service Equipment to Meter Bank (For 20 Dwelling Units)

Lighting and Small-Appliance Load	
20 units × 5520 VA	110,400 VA
First 3000 VA at 100%	3,000 VA
110,400 VA – 3000 VA = 107,400 VA at 35%	37,590 VA
Net Calculated Load	40,590 VA
20 ranges: 35,000 VA at 70% [ <i>see</i> Table 220.55 and 220.61(B)]	24,500 VA
Total	65,090 VA
65,090 VA ÷ 240 V = 271 A	

### Further Demand Factor [*see* 220.61(B)]

First 200 A at 100%	200 A
Balance: 271 A – 200 A = 71 A at 70%	50 A
Total	250 A

### Feeder Neutral Load of Main Feeder (Less House Load) (For 40 Dwelling Units)

Lighting and Small-Appliance Load	
40 units × 5520 VA	220,800 VA
First 3000 VA at 100%	3,000 VA
Next 120,000 VA – 3000 VA = 117,000 VA at 35%	40,950 VA
Remainder 220,800 VA – 120,000 VA = 100,800 VA at 25%	25,200 VA
Net Calculated Load	69,150 VA
40 ranges: 55,000 VA at 70% [ <i>see</i> Table 220.55 and 220.61(B)]	38,500 VA
Total	107,650 VA
107,650 VA ÷ 240 V = 449 A	

### Further Demand Factor [*see* 220.61(B)]

First 200 A at 100%	200 A
Balance: 449 – 200 A = 249 A at 70%	174 A
Total	374 A

### Example D5(a) Multifamily Dwelling Served at 208Y/120 Volts, Three Phase

All conditions and calculations are the same as for the multifamily dwelling [Example D4(a)] served at 120/240 V, single phase except as follows:  
Service to each dwelling unit would be two phase legs and neutral.

### Minimum Number of Branch Circuits Required for Each Dwelling Unit (*see* 210.11)

Range Circuit: 8000 VA ÷ 208 V = 38 A or a circuit of two 8 AWG conductors and one 10 AWG conductor **in accordance with** 210.19(A)(3)

### Minimum Size Feeder Required for Each Dwelling Unit (*see* 215.2)

For 120/208-V, 3-wire system (without ranges),  
Net calculated load of 3882 VA ÷ 2 legs ÷ 120 V/leg = **16 A**  
For 120/208-V, 3-wire system (with ranges),  
Net calculated load (range) of 8000 VA ÷ 208 V = **39 A**  
Total load (range + lighting) = 38.5 A + 16.2 A = 54.7 A  
Feeder neutral: (range) of 8000 VA × 70% = 5600 VA ÷ 208 V = **27 A**  
Total load: (range + lighting) = **27 A** + **16 A** = **43 A**

### Minimum Size Feeders Required from Service Equipment to Meter Bank (For 20 Dwelling Units — 10 with Ranges)

For 208Y/120-V, 3-phase, 4-wire system,  
Ranges: Maximum number between any two phase legs = 4  
2 × 4 = 8.  
Table 220.55 demand = 23,000 VA  
Per phase demand = 23,000 VA ÷ 2 = 11,500 VA  
Equivalent 3-phase load = 34,500 VA  
Net Calculated Load (total):  
40,590 VA + 34,500 VA = 75,090 VA  
75,090 VA ÷ (208 V)(1.732) = **208 A**

### Feeder Neutral Size

Net Calculated Lighting and Appliance Load & Equivalent Range Load:  
40,590 VA + (34,500 VA at 70%) = 64,700 VA

Net Calculated Neutral Load:

$$64,700 \text{ VA} \div (208 \text{ V})(1.732) = 180 \text{ A}$$

**Minimum Size Main Feeder (Less House Load) (For 40 Dwelling Units — 20 with Ranges)**

For 208Y/120-V, 3-phase, 4-wire system,

Ranges:

Maximum number between any two phase legs = 7

$$2 \times 7 = 14.$$

Table 220.55 demand = 29,000 VA

Per phase demand = 29,000 VA  $\div$  2 = 14,500 VA

Equivalent 3-phase load = 43,500 VA

Net Calculated Load (total):

$$69,150 \text{ VA} + 43,500 \text{ VA} = 112,650 \text{ VA}$$

$$112,650 \text{ VA} \div (208 \text{ V})(1.732) = 313 \text{ A}$$

Main Feeder Neutral Size:

$$69,150 \text{ VA} + (43,500 \text{ VA at } 70\%) = 99,600 \text{ VA}$$

$$99,600 \text{ VA} \div (208 \text{ V})(1.732) = 277 \text{ A}$$

**Further Demand Factor** (see 220.61)

$$200 \text{ A at } 100\% \quad 200.0 \text{ A}$$

$$277 \text{ A} - 200 \text{ A} = 77 \text{ A at } 70\% \quad 54 \text{ A}$$

$$\text{Net Calculated Load (neutral)} \quad 254 \text{ A}$$

**Example D5(b) Optional Calculation for Multifamily Dwelling Served at 208Y/120 Volts, Three Phase**

All conditions and calculations are the same as for Optional Calculation for the Multifamily Dwelling [Example D4(b)] served at 120/240 V, single phase except as follows:

Service to each dwelling unit would be two phase legs and neutral.

**Minimum Number of Branch Circuits Required for Each Dwelling Unit** (see 210.11)

Range Circuit (see Table 220.55, Column B): 8000 VA at 80%  $\div$  208 V =

31 A or a circuit of two 8 AWG conductors and one 10 AWG conductor in accordance with 210.19(A)(3)

Space Heating: 6000 VA  $\div$  208 V = 29 A

Two 20-ampere, 2-pole circuits required, 12 AWG conductors

**Minimum Size Feeder Required for Each Dwelling Unit**

120/208-V, 3-wire circuit

Net calculated load of 18,782 VA  $\div$  208 V = 90 A

Net calculated load (lighting line to neutral):

$$3882 \text{ VA} \div 2 \text{ legs} \div 120 \text{ V per leg} = 16 \text{ amperes}$$

Line to line = 14,900 VA  $\div$  208 V = 72 A

Total load = 16.2 A + 71.6 A = 88 A

**Minimum Size Feeder Required for Service Equipment to Meter Bank (For 20 Dwelling Units)**

**Net Calculated Load**

$$167,352 \text{ VA} \div (208 \text{ V})(1.732) = 465 \text{ A}$$

**Feeder Neutral Load**

$$65,080 \text{ VA} \div (208 \text{ V})(1.732) = 181 \text{ A}$$

**Minimum Size Main Feeder Required (Less House Load) (For 40 Dwelling Units)**

**Net Calculated Load**

$$246,624 \text{ VA} \div (208 \text{ V})(1.732) = 685 \text{ A}$$

**Main Feeder Neutral Load**

$$107,650 \text{ VA} \div (208 \text{ V})(1.732) = 299 \text{ A}$$

**Further Demand Factor** [see 220.61(B)]

$$200 \text{ A at } 100\% \quad 200.0 \text{ A}$$

$$299 \text{ A} - 200 \text{ A} = 99 \text{ A at } 70\% \quad 69 \text{ A}$$

$$\text{Net Calculated Load (neutral)} \quad 269 \text{ A}$$

**Example D6 Maximum Demand for Range Loads**

Table 220.55, Column C, applies to ranges not over 12 kW. The application of Note 1 to ranges over 12 kW (and not over 27 kW) and Note 2 to ranges over 8½ kW (and not over 27 kW) is illustrated in the following two examples.

**A. Ranges All the Same Rating** (see Table 220.55, Note 1)

Assume 24 ranges, each rated 16 kW.

From Table 220.55, Column C, the maximum demand for 24 ranges of 12-kW rating is 39 kW. 16 kW exceeds 12 kW by 4.

$$5\% \times 4 = 20\% \text{ (5\% increase for each kW in excess of 12)}$$

$$39 \text{ kW} \times 20\% = 7.8 \text{ kW increase}$$

$$39 + 7.8 = 46.8 \text{ kW (value to be used in selection of feeders)}$$

**B. Ranges of Unequal Rating** (see Table 220.55, Note 2)

Assume 5 ranges, each rated 11 kW; 2 ranges, each rated 12 kW; 20 ranges, each rated 13.5 kW; 3 ranges, each rated 18 kW.

$$\begin{array}{rcl} 5 \text{ ranges} & \times 12 \text{ kW} = & 60 \text{ kW (use} \\ & & 12 \text{ kW for range rated less than 12)} \end{array}$$

$$2 \text{ ranges} \quad \times 12 \text{ kW} = \quad 24 \text{ kW}$$

$$20 \text{ ranges} \quad \times 13.5 \text{ kW} = \quad 270 \text{ kW}$$

$$3 \text{ ranges} \quad \times 18 \text{ kW} = \quad 54 \text{ kW}$$

$$30 \text{ ranges,} \quad \text{Total kW} = \quad 408 \text{ kW}$$

$$408 \div 30 \text{ ranges} = 13.6 \text{ kW (average to be used for calculation)}$$

From Table 220.55, Column C, the demand for 30 ranges of 12-kW rating is 15 kW + 30 (1 kW  $\times$  30 ranges) = 45 kW. 13.6 kW exceeds 12 kW by 1.6 kW (use 2 kW).

$$5\% \times 2 = 10\% \text{ (5\% increase for each kW in excess of 12 kW)}$$

$$45 \text{ kW} \times 10\% = 4.5 \text{ kW increase}$$

$$45 \text{ kW} + 4.5 \text{ kW} = 49.5 \text{ kW (value to be used in selection of feeders)}$$

**Example D8 Motor Circuit Conductors, Overload Protection, and Short-Circuit and Ground-Fault Protection** (see 240.6, 430.6, 430.22, 430.23, 430.24, 430.32, 430.52, and 430.62, Table 430.52, and Table 430.250)

Determine the minimum required conductor ampacity, the motor overload protection, the branch-circuit short-circuit and ground-fault protection, and the feeder protection, for three induction-type motors on a 480-V, 3-phase feeder, as follows:

(a) One 25-hp, 460-V, 3-phase, squirrel-cage motor, nameplate full-load current 32 A, Design B, Service Factor 1.15

(b) Two 30-hp, 460-V, 3-phase, wound-rotor motors, nameplate primary full-load current 38 A, nameplate secondary full-load current 65 A, 40°C rise.

**Conductor Ampacity**

The full-load current value used to determine the minimum required conductor ampacity is obtained from Table 430.250 [see 430.6(A)] for the squirrel-cage motor and the primary of the wound-rotor motors. To obtain the minimum required conductor ampacity, the full-load current is multiplied by 1.25 [see 430.22 and 430.23(A)].

For the 25-hp motor,

$$34 \text{ A} \times 1.25 = 43 \text{ A}$$

For the 30-horsepower motors,

$$40 \text{ A} \times 1.25 = 50 \text{ A}$$

$$65 \text{ A} \times 1.25 = 81 \text{ A}$$

**Motor Overload Protection**

Where protected by a separate overload device, the motors are required to have overload protection rated or set to trip at not more than 125% of the nameplate full-load current [see 430.6(A) and 430.32(A)(1)].

For the 25-hp motor,

$$32 \text{ A} \times 1.25 = 40.0 \text{ A}$$

For the 30-hp motors,

$$38 \text{ A} \times 1.25 = 48 \text{ A}$$

Where the separate overload device is an overload relay (not a fuse or circuit breaker), and the overload device selected at 125% is not sufficient to start the motor or carry the load, the trip setting is permitted to be increased in accordance with 430.32(C).

#### Branch-Circuit Short-Circuit and Ground-Fault Protection

The selection of the rating of the protective device depends on the type of protective device selected, in accordance with 430.52 and Table 430.52. The following is for the 25-hp motor.

(a) Nontime-Delay Fuse: The fuse rating is  $300\% \times 34 \text{ A} = 102 \text{ A}$ . The next larger standard fuse is 110 A [see 240.6 and 430.52(C)(1), Exception No. 1]. If the motor will not start with a 110-A nontime-delay fuse, the fuse rating is permitted to be increased to 125 A because this rating does not exceed 400% [see 430.52(C)(1), Exception No. 2(a)].

(b) Time-Delay Fuse: The fuse rating is  $175\% \times 34 \text{ A} = 59.5 \text{ A}$ . The next larger standard fuse is 60 A [see 240.6 and 430.52(C)(1), Exception No. 1]. If the motor will not start with a 60-A time-delay fuse, the fuse rating is permitted to be increased to 70 A because this rating does not exceed 225% [see 430.52(C)(1), Exception No. 2(b)].

#### Feeder Short-Circuit and Ground-Fault Protection

The rating of the feeder protective device is based on the sum of the largest branch-circuit protective device (example is 110 A) plus the sum of the full-load currents of the other motors, or  $110 \text{ A} + 40 \text{ A} + 40 \text{ A} = 190 \text{ A}$ . The nearest standard fuse that does not exceed this value is 175 A [see 240.6 and 430.62(A)].

#### Example D9 Feeder Ampacity Determination for Generator Field Control [see 215.2, 430.24, 430.24 Exception No. 1, 620.13, 620.14, 620.61, and Table 430.22(E) and 620.14]

Determine the conductor ampacity for a 460-V 3-phase, 60-Hz ac feeder supplying a group of six elevators. The 460-V ac drive motor nameplate rating of the largest MG set for one elevator is 40 hp and 52 A, and the remaining elevators each have a 30-hp, 40-A, ac drive motor rating for their MG sets. In addition to a motor controller, each elevator has a separate motion/operation controller rated 10 A continuous to operate microprocessors, relays, power supplies, and the elevator car door operator. The MG sets are rated continuous.

#### Conductor Ampacity. Conductor ampacity is determined as follows:

(a) In accordance with 620.13(D) and 620.61(B)(1), use Table 430.22(E), for intermittent duty (elevators). For intermittent duty using a continuous rated motor, the percentage of nameplate current rating to be used is 140%.

(b) For the 30-hp ac drive motor,

$$140\% \times 40 \text{ A} = 56 \text{ A}.$$

(c) For the 40-hp ac drive motor,

$$140\% \times 52 \text{ A} = 73 \text{ A}.$$

(d) The total conductor ampacity is the sum of all the motor currents:  $(1 \text{ motor} \times 73 \text{ A}) + (5 \text{ motors} \times 56 \text{ A}) = 353 \text{ A}$

(e) In accordance with 620.14 and Table 620.14, the conductor (feeder) ampacity would be permitted to be reduced by the use of a demand factor. Constant loads are not included (see 620.14, Informational Note). For six elevators, the demand factor is 0.79. The feeder diverse ampacity is, therefore,  $0.79 \times 353 \text{ A} = 279 \text{ A}$ .

(f) In accordance with 430.24 and 215.3, the controller continuous current is  $125\% \times 10 \text{ A} = 13 \text{ A}$

(g) The total feeder ampacity is the sum of the diverse current and all the controller continuous current.

$$I_{\text{total}} = 279 \text{ A} + (6 \text{ elevators} \times 12.5 \text{ A}) = 354 \text{ A}$$

(h) This ampacity would be permitted to be used to select the wire size.

See Figure D9.

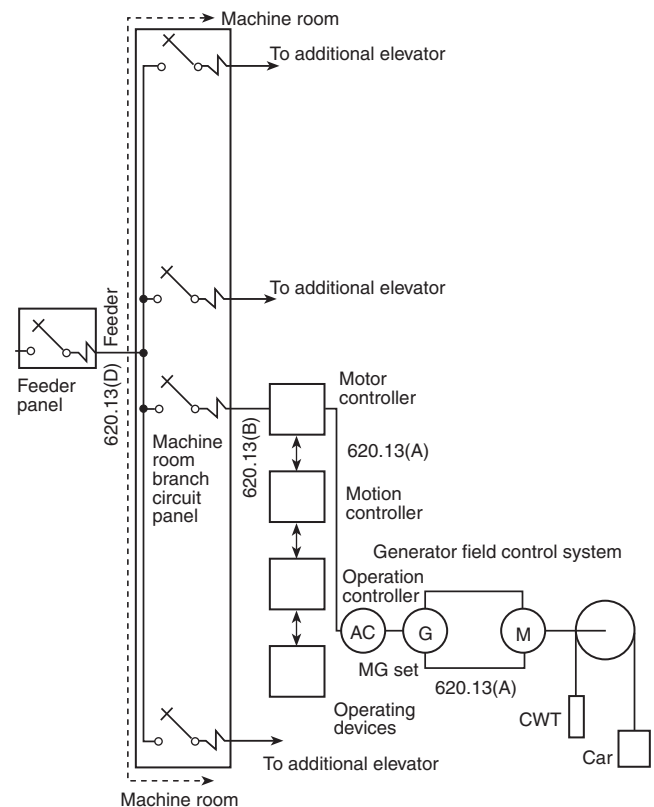

FIGURE D9 Generator Field Control.

#### Example D10 Feeder Ampacity Determination for Adjustable Speed Drive Control [see 215.2, 430.24, 620.13, 620.14, 620.61, and Table 430.22(E)]

Determine the conductor ampacity for a 460-V, 3-phase, 60-Hz ac feeder supplying a group of six identical elevators. The system is adjustable-speed SCR dc drive. The power transformers are external to the drive (motor controller) cabinet. Each elevator has a separate motion/operation controller connected to the load side of the main line disconnect switch rated 10 A continuous to operate microprocessors, relays, power supplies, and the elevator car door operator. Each transformer is rated 95 kVA with an efficiency of 90%.

#### Conductor Ampacity

Conductor ampacity is determined as follows:

(a) Calculate the nameplate rating of the transformer:

$$I = \frac{95 \text{ kVA} \times 1000}{\sqrt{3} \times 460 \text{ V} \times 0.90_{\text{eff}}} = 133 \text{ A}$$

(b) In accordance with 620.13(D), for six elevators, the total conductor ampacity is the sum of all the currents.

$$6 \text{ elevators} \times 133 \text{ A} = 798 \text{ A}$$

(c) In accordance with 620.14 and Table 620.14, the conductor (feeder) ampacity would be permitted to be reduced by the use of a demand factor. Constant loads are not included (see 620.13, Informational Note No. 2). For six elevators, the demand factor is 0.79. The feeder diverse ampacity is, therefore,  $0.79 \times 798 \text{ A} = 630 \text{ A}$ .

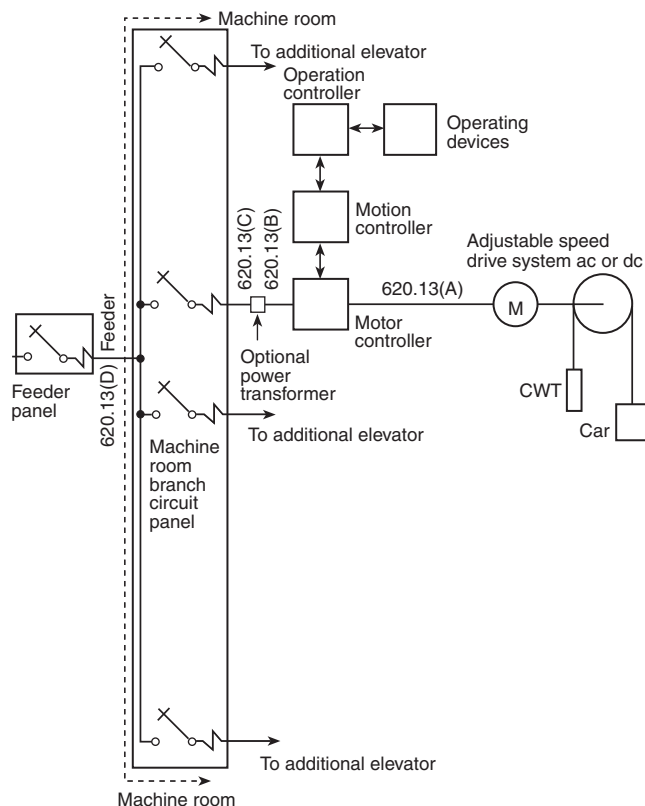

(d) In accordance with 430.24 and 215.3, the controller continuous current is  $125\% \times 10 \text{ A} = 13 \text{ A}$ .

(e) The total feeder ampacity is the sum of the diverse current and all the controller constant current.

$$I_{\text{total}} = 630 \text{ A} + (6 \text{ elevators} \times 12.5 \text{ A}) = 705 \text{ A}$$

(f) This ampacity would be permitted to be used to select the wire size.

See Figure D10.

**FIGURE D10 Adjustable Speed Drive Control.**

#### Example D11 Mobile Home (see 550.18)

A mobile home floor is 70 ft by 10 ft and has two small appliance circuits; a 1000-VA, 240-V heater; a 200-VA, 120-V exhaust fan; a 400-VA, 120-V dishwasher; and a 7000-VA electric range.

#### Lighting and Small-Appliance Load

Lighting (70 ft × 10 ft × 3 VA per ft <sup>2</sup> )	2,100 VA
Small-appliance (1500 VA × 2 circuits)	3,000 VA
Laundry (1500 VA × 1 circuit)	1,500 VA
<b>Subtotal</b>	<b>6,600 VA</b>
First 3000 VA at 100%	3,000 VA
Remainder (6600 VA – 3000 VA = 3600 VA) × 35%	1,260 VA
<b>Total</b>	<b>4,260 VA</b>

$$4260 \text{ VA} \div 240 \text{ V} = 17.75 \text{ A per leg}$$

Amperes per Leg	Leg A	Leg B
Lighting and appliances	18	18
Heater (1000 VA ÷ 240 V)	4	4
Fan (200 VA × 125% ÷ 120 V)	2	—
Dishwasher (400 VA ÷ 120 V)	—	3
Range (7000 VA × 0.8 ÷ 240 V)	23	23
<b>Total amperes per leg</b>	<b>47</b>	<b>48</b>

Based on the higher current calculated for either leg, a minimum 50-A supply cord would be required.

For SI units, 0.093 m<sup>2</sup> = 1 ft<sup>2</sup> and 0.3048 m = 1 ft.

#### Example D12 Park Trailer (see 552.47)

A park trailer floor is 40 ft by 10 ft and has two small appliance circuits, a 1000-VA, 240-V heater, a 200-VA, 120-V exhaust fan, a 400-VA, 120-V dishwasher, and a 7000-VA electric range.

#### Lighting and Small-Appliance Load

Lighting (40 ft × 10 ft × 3 VA per ft <sup>2</sup> )	1,200 VA
Small-appliance (1500 VA × 2 circuits)	3,000 VA
Laundry (1500 VA × 1 circuit)	1,500 VA
<b>Subtotal</b>	<b>5,700 VA</b>
First 3000 VA at 100%	3,000 VA
Remainder (5700 VA – 3000 VA = 2700 VA) × 35%	945 VA
<b>Total</b>	<b>3,945 VA</b>

$$3945 \text{ VA} \div 240 \text{ V} = 16.44 \text{ A per leg}$$

Amperes per Leg	Leg A	Leg B
Lighting and appliances	16	16
Heater (1000 VA ÷ 240 V)	4	4
Fan (200 VA × 125% ÷ 120 V)	2	—
Dishwasher (400 VA ÷ 120 V)	—	3
Range (7000 VA × 0.8 ÷ 240 V)	23	23
<b>Totals</b>	<b>45</b>	<b>46</b>

Based on the higher current calculated for either leg, a minimum 50-A supply cord would be required.

For SI units, 0.093 m<sup>2</sup> = 1 ft<sup>2</sup> and 0.3048 m = 1 ft.

#### Example D13 Cable Tray Calculations (See Article 392)

##### D13(a) Multiconductor Cables 4/0 AWG and Larger

Use: NEC 392.22(A)(1)(a)

Cable tray must have an inside width equal to or greater than the sum of the diameters (Sd) of the cables, which must be installed in a single layer.

**Example:** Cable tray width is obtained as follows:

Cable Size Being Used	(OD) Cable Outside Diameters (in.)	(N) Number of Cables	SD = (OD) × (N) (Sum of the Cable Diameters) (in.)
3-conductor Type MC cable — 4/0 AWG	1.57	12	18.84

The sum of the diameters (Sd) of all cables = 18.84 in., therefore a cable tray with an inside width of at least 18.84 in. is required.

Note: Cable outside diameter is a nominal diameter from catalog data.

##### D13(b) Multiconductor Cables Smaller Than 4/0 AWG

Use: NEC 392.22(A)(1)(b)

The sum of the cross-sectional areas of all the cables to be installed in the cable tray must be equal to or less than the allowable cable area for the tray width, as indicated in Table 392.22(A), Column 1.

**Example:** Cable tray width is obtained as follows:

Cable Size Being Used	(A) Cable Cross-Sectional Area (in. <sup>2</sup> )	(N) Number of Cables	Multiply (A) × (N) (Which Is a Total Cable Cross-Sectional Area in in. <sup>2</sup> )
4-conductor Type MC cable — 1 AWG	1.1350	9	12.15

TABLE D13(b) from Table 392.22(A), Column 1

Inside Width of Cable Tray (in.)	Allowable Cable Area (in. <sup>2</sup> )
6	7.0
9	10.5
12	14.0
18	21.0
24	28.0
30	35.0
36	42.0

The total cable cross-sectional area is 12.15 in.<sup>2</sup>. Using Table D13(b) above, the next higher allowable cable area must be used, which is 14.0 in.<sup>2</sup>. The table specifies that the cable tray inside width for an allowable cable area of 14.0 in.<sup>2</sup> is 12 in.

Note: Cable cross-sectional area is a nominal area from catalog data.

#### D13(c) Single Conductor Cables 1/0 AWG through 4/0 AWG

Use: NEC 392.22(B)(1)(d)

Cable tray must have an inside width equal to or greater than the sum of the diameters (Sd) of the cables. The cables must be evenly distributed across the cable tray.

**Example:** Cable tray width is obtained as follows:

Single Conductor Cable Size Being Used	(OD) Cable Outside Diameters (in.)	(N) Number of Cables	Sd = (OD) × (N) (Sum of the Cable Diameters) (in.)
THHN — 4/0 AWG	0.642	18	11.556

The sum of the diameters (Sd) of all cables = 11.56 in., therefore, a cable tray with an inside width of at least 11.56 in. is required.

Note: Cable outside diameter from Chapter 9, Table 5.

TABLE D13(d) from Table 392.22(B)(1), Column 1

Inside Width of Cable Tray (in.)	Allowable Cable Area (in. <sup>2</sup> )
6	6.5
9	9.5
12	13.0
18	19.5
24	26.0
30	32.5
36	39.0

#### D13(d) Single Conductor Cables 250 kcmil through 900 kcmil

Use: NEC 392.22(B)(1)(b)

The sum of the cross-sectional areas of all the cables to be installed in the cable tray must be equal to or less than the allowable cable area for the tray width, as indicated in Table 392.22(B)(1), Column 1.

**Example:** Cable tray width is obtained as follows:

Cable Size Being Used	(A) Cable Cross- Sectional Area (in. <sup>2</sup> )	(N) Number of Cables	Multiply (A) × (N) (Which Is a Total Cable Cross- Sectional Area in in. <sup>2</sup> )
THHN — 500 kcmil	0.707	9	6.36

The total cable cross-sectional area is 6.36 in.<sup>2</sup>. Using Table D13(d), the next higher allowable cable area must be used, which is 6.5 in.<sup>2</sup>. The table specifies that the cable tray inside width for an allowable cable area of 6.5 in.<sup>2</sup> is 6 in.

Note: Single-conductor cable cross-sectional area from Chapter 9, Table 5.

# Informative Annex

## Types of Construction

*This informative annex is not a part of the requirements of this NFPA document but is included for informational purposes only.*

Table E.1 contains the fire resistance rating, in hours, for Types I through V construction. The five different types of construction can be summarized briefly as follows (see also Table E.2):

Type I is a Fire-Resistive construction type. All structural elements and most interior elements are required to be noncombustible. Interior, nonbearing partitions are permitted to be 1 or 2 hour rated. For nearly all occupancy types, Type I construction can be of unlimited height.

Type II construction has 3 categories: Fire-Resistive, One-Hour Rated, and Non-Rated. The number of stories permitted for multifamily dwellings varies from two for Non-Rated and four for One-Hour Rated to 12 for Fire-Resistive construction.

Type III construction has two categories: One-Hour Rated and Non-Rated. Both categories require the structural framework and exterior walls to be of noncombustible material. One-Hour Rated construction requires all interior partitions to be one-hour rated. Non-Rated construction allows nonbearing interior partitions to be of non-rated construction. The maximum permitted number of stories for multifamily dwellings and other structures is two for Non-Rated and four for One-Hour Rated.

Type IV is a single construction category that provides for heavy timber construction. Both the structural framework and the exterior walls are required to be noncombustible except that wood members of certain minimum sizes are allowed. This construction type is seldom used for multifamily dwellings but, if used, would be permitted to be four stories high.

Type V construction has two categories: One-Hour Rated and Non-Rated. One-Hour Rated construction requires a minimum of one-hour rated construction throughout the building. Non-rated construction allows non-rated interior partitions with certain restrictions. The maximum per-

mitted number of stories for multifamily dwellings and other structures is 2 for Non-Rated and 3 for One-Hour Rated.

In Table E.1 the system of designating types of construction also includes a specific breakdown of the types of construction through the use of arabic numbers. These arabic numbers follow the roman numeral notation where identifying a type of construction [for example, Type I(442), Type II(111), Type III(200)] and indicate the fire resistance rating requirements for certain structural elements as follows:

- (1) First arabic number — exterior bearing walls
- (2) Second arabic number — columns, beams, girders, trusses and arches, supporting bearing walls, columns, or loads from more than one floor
- (3) Third arabic number — floor construction

Table E.3 provides a comparison of the types of construction for various model building codes. [**5000**: A.7.2.1.1]

Table E.3 is reproduced from NFPA 5000®-2009, *Building Construction and Safety Code*®. This table cross-references the building construction types described in NFPA 220-2009, *Standard on Types of Building Construction*, to the construction types described in four other model building codes. For authorities having jurisdiction in a municipality where one of these model building codes is used, this table provides helpful information to assist in the proper application of 334.10(2) and 334.10(3) and 334.10(5) covering the permitted use of Type NM cable based on building construction type. The types of construction are based on NFPA 220, and Table E.3 facilitates assimilation of the 334.10 and 334.12 requirements with the construction types contained within the building code that is adopted by a jurisdiction.

**TABLE E.1 Fire Resistance Ratings for Type I Through Type V Construction (hr)**

	Type I		Type II			Type III		Type IV	Type V

# Informative Annex

## Availability and Reliability for Critical Operations Power Systems; and Development and Implementation of Functional Performance Tests (FPTs) for Critical Operations Power Systems

*This informative annex is not a part of the requirements of this NFPA document but is included for informational purposes only.*

**I. Availability and Reliability for Critical Operations Power Systems.** Critical operations power systems may support facilities with a variety of objectives that are vital to public safety. Often these objectives are of such critical importance that system downtime is costly in terms of economic losses, loss of security, or loss of mission. For those reasons, the availability of the critical operations power system, the percentage of time that the system is in service, is important to those facilities. Given a specified level of availability, the reliability and maintainability requirements are then derived based on that availability requirement.

**Availability.** Availability is defined as the percentage of time that a system is available to perform its function(s). Availability is measured in a variety of ways, including the following:

$$\text{Availability} = \frac{MTBF}{MTBF + MTTR}$$

where:

*MTBF* = mean time between failures

*MTTF* = mean time to failure

*MTTR* = mean time to repair

See the following table for an example of how to establish required availability for critical operation power systems:

Availability	Hours of Downtime*
0.9	876
0.99	87.6
0.999	8.76
0.9999	0.876
0.99999	0.0876
0.999999	0.00876
0.9999999	0.000876

\*Based on a year of 8760 hours.

Availability of a system in actual operations is determined by the following:

- (1) The frequency of occurrence of failures. Failures may prevent the system from performing its function or may cause a degraded effect on system operation. Frequency of failures is directly related to the system's level of reliability.
- (2) The time required to restore operations following a system failure or the time required to perform maintenance to prevent a failure. These times are determined in part by the system's level of maintainability.

- (3) The logistics provided to support maintenance of the system. The number and availability of spares, maintenance personnel, and other logistics resources (refueling, etc.) combined with the system's level of maintainability determine the total downtime following a system failure.

**Reliability.** Reliability is concerned with the probability and frequency of failures (or lack of failures). A commonly used measure of reliability for repairable systems is *MTBF*. The equivalent measure for nonrepairable items is *MTTF*. Reliability is more accurately expressed as a probability over a given duration of time, cycles, or other parameter. For example, the reliability of a power plant might be stated as 95 percent probability of no failure over a 1000-hour operating period while generating a certain level of power. Reliability is usually defined in two ways (the electrical power industry has historically not used these definitions):

- (1) The duration or probability of failure-free performance under stated conditions
- (2) The probability that an item can perform its intended function for a specified interval under stated conditions [For nonredundant items, this is equivalent to the preceding definition (1). For redundant items this is equivalent to the definition of mission reliability.]

**Maintainability.** Maintainability is a measure of how quickly and economically failures can be prevented through preventive maintenance, or system operation can be restored following failure through corrective maintenance. A commonly used measure of maintainability in terms of corrective maintenance is the mean time to repair (*MTTR*). Maintainability is not the same thing as maintenance. It is a design parameter, while maintenance consists of actions to correct or prevent a failure event.

**Improving Availability.** The appropriate methods to use for improving availability depend on whether the facility is being designed or is already in use. For both cases, a reliability/availability analysis should be performed to determine the availability of the old system or proposed new system in order to ascertain the hours of downtime (see the preceding table). The AHJ or government agency should dictate how much downtime is acceptable.

**Existing facilities:** For a facility that is being operated, two basic methods are available for improving availability when the current level of availability is unacceptable: (1) Selectively adding redundant units (e.g., generators, chillers, fuel supply to eliminate sources of single-point failure, and (2) optimizing maintenance using a reliability-centered maintenance (RCM) approach to minimize downtime. [Refer to NFPA 70B-2010, *Recommended Practice for Electrical Equipment Maintenance*.] A combination of the previous two methods can also be implemented. A third very

expensive method is to redesign subsystems or to replace components and subsystems with higher reliability items. [Refer to NFPA 70B.]

**New facilities:** The opportunity for high availability and reliability is greatest when designing a new facility. By applying an effective reliability strategy, designing for maintainability, and ensuring that manufacturing and commissioning do not negatively affect the inherent levels of reliability and maintainability, a highly available facility will result. The approach should be as follows:

- (1) *Develop and determine a reliability strategy* (establish goals, develop a system model, design for reliability, conduct reliability development testing, conduct reliability acceptance testing, design system delivery, maintain design reliability, maintain design reliability in operation).
- (2) *Develop a reliability program.* This is the application of the reliability strategy to a specific system, process, or function. Each step in the preceding strategy requires the selection and use of specific methods and tools. For example, various tools can be used to develop requirements or evaluate potential failures. To derive requirements, analytical models can be used, for example, quality function development (a technique for deriving more detailed, lower-level requirements from one level to another, beginning with mission requirements, i.e., customer needs). This model was developed as part of the total quality management movement. Parametric models can also be used to derive design values of reliability from operational values and vice versa. Analytical methods include but are not limited to things such as thermal analysis, durability analysis, and predictions. Finally, one should evaluate possible failures. A failure modes and effects criticality analysis (FMECA) and fault tree analysis (FTA) are two methods for evaluating possible failures. The mission facility engineer should determine which method to use or whether to use both.
- (3) *Identify Reliability Requirements.* The entire effort for designing for reliability begins with identifying the mission critical facility's reliability requirements. These requirements are stated in a variety of ways, depending on the customer and the specific system. For a mission-critical facility, it would be the mission success probability.

## II. Development and Implementation of Functional Performance Tests (FPTs) for Critical Operations Power Systems Development of FPT

- (1) **Submit Functional Performance Tests (FPTs).** System/component tests or FPTs are developed from submitted drawings, systems operating documents (SODs), and systems operation and maintenance manuals (SOMMs), including large component testing (i.e., transformers, cable,

generators, UPS), and how components operate as part of the total system. The commissioning authority develops the test and cannot be the installation contractor (or subcontractor).

As the equipment/components/systems are installed, quality assurance procedures are administered to verify that components are installed in accordance with minimum manufacturers' recommendations, safety codes, and acceptable installation practices. Quality assurance discrepancies are then identified and added to a "commissioning action list" that must be rectified as part of the commissioning program. These items would usually be discussed during commissioning meetings. Discrepancies are usually identified initially by visual inspection.

**(2) Review FPTs.** The tests must be reviewed by the customer, electrical contractors, quality assurance personnel, maintenance personnel, and other key personnel (the commissioning team). Areas of concern include, among others, all functions of the system being tested, all major components included, whether the tests reflect the system operating documents, and verification that the tests make sense.

**(3) Make Changes to FPTs as Required.** The commissioning authority then implements the corrections, questions answered, and additions.

**(4) FPTs Approval.** After the changes are made to the FPTs, they are submitted to the commissioning team. When

it is acceptable, the customer or the designated approval authority approves the FPTs. It should be noted that even though the FPT is approved, problems that arise during the test (or areas not covered) must be addressed.

**Testing Implementation for FPTs.** The final step in the successful commissioning plan is testing and proper execution of system-integrated tests.

**(1) Systems Ready to Operate.** The FPTs can be implemented as various systems become operative (i.e., test for the generator system) or when the entire system is installed. However, the final "pull the plug" test is performed only after all systems are completely installed. If the electrical contractor (or subcontractor) implements the FPTs, a witness must initial each step of the test. The electrical contractor cannot employ the witness directly or indirectly.

**(2) Perform Tests (FPTs).** If the system fails the test, the problem must be resolved and the equipment or system re-tested or the testing requirements re-analyzed until successful tests are witnessed. Once the system or equipment passes testing, it is verified by designated commissioning official.

**(3) Customer Receives System.** After all tests are completed (including the "pull the plug" test), the system is turned over to the customer.

# Informative Annex

## Supervisory Control and Data Acquisition (SCADA)

*This informative annex is not a part of the requirements of this NFPA document, but is included for informational purposes only.*

**(A) General.** Where provided, the general requirements in (A)(1) through (A)(11) shall apply to SCADA systems. The SCADA system for the COPS loads shall be separate from the building management SCADA system. No single point failure shall be able to disable the SCADA system.

- (1) The SCADA system for the COPS loads shall be separate from the building management SCADA system.
- (2) No single point failure shall be able to disable the SCADA system.
- (3) The SCADA system shall be permitted to provide control and monitor electrical and mechanical utility systems related to mission critical loads, including, but not limited to the following:
  - a. The fire alarm system
  - b. The security system
  - c. Power distribution
  - d. Power generation
  - e. HVAC and ventilation (damper position, airflow speed and direction)
  - f. Load shedding
  - g. Fuel levels or hours of operation
- (4) Before installing or employing a SCADA system, an operations and maintenance analysis and risk assessment shall be performed to provide the maintenance parameter data
- (5) A redundant system shall be provided in either warm or hot standby.
- (6) The controller shall be a programmable logic controller (PLC).
- (7) The SCADA system shall utilize open, not proprietary, protocols.

- (8) The SCADA system shall be able to assess the damage and determine system integrity after the “event.”
- (9) The monitor display shall provide graphical user interface for all major components monitored and controlled by the SCADA system, with color schemes readily recognized by the typical user.
- (10) The SCADA system shall have the capability to provide storage of critical system parameters at a 15-minute rate or more often when out-of-limit conditions exist.
- (11) The SCADA system shall have a separate data storage facility not located in the same vicinity.

**(B) Power Supply.** The SCADA system power supply shall comply with (B)(1) through (B)(3):

- (1) The power supply shall be provided with a direct-current station battery system, rated between 24 and 125 volts dc, with a 72-hour capacity.
- (2) The batteries of the SCADA system shall be separate from the batteries for other electrical systems.
- (3) The power supply shall be provided with a properly installed surge-protective device (TVSS) at its terminals with a direct low-impedance path to ground. Protected and unprotected circuits shall be physically separated to prevent coupling.

**(C) Security Against Hazards.** Security against hazards shall be provided in accordance with (C)(1) through (C)(6):

- (1) Controlled physical access by authorized personnel to only the system operational controls and software shall be provided.

- (2) The SCADA system shall be protected against dust, dirt, water, and other contaminants by specifying enclosures appropriate for the environment.
- (3) Conduit and tubing shall not violate the integrity of the SCADA system enclosure.
- (4) The SCADA system shall be located in the same secure locations as the secured systems that they monitor and control.
- (5) The SCADA system shall be provided with dry agent fire protection systems or double interlocked preaction sprinkler systems using cross-zoned detection, to minimize the threat of accidental water discharge into unprotected equipment. The fire protection systems shall be monitored by the fire alarm system in accordance with *NFPA 72-2010, National Fire Alarm and Signaling Code*.
- (6) The SCADA system shall not be connected to other network communications outside the secure locations without encryption or use of fiber optics.

**(D) Maintenance and Testing.** SCADA systems shall be maintained and tested in accordance with (D)(1) and (D)(2).

**(1) Maintenance.** The maintenance program for SCADA systems shall consist of the following components:

- (1) A documented preventive maintenance program
- (2) Concurrent maintenance capabilities, to allow the testing, troubleshooting, repair, and/or replacement of a component or subsystem while redundant component(s) or subsystem(s) are serving the load
- (3) Retention of operational data — the deleted material goes well beyond requirements to ensure proper maintenance and operation

**(2) Testing.** SCADA systems shall be tested periodically under actual or simulated contingency conditions.

Informational Note No. 1: Periodic system testing procedures can duplicate or be derived from the recommended functional performance testing procedures of individual components, as provided by the manufacturers.

Informational Note No. 2: For more information on maintenance and testing of SCADA, see NFPA 70B-2010, *Recommended Practice for Electrical Equipment Maintenance*.

# Informative Annex

## Administration and Enforcement

*Informative Annex H is not a part of the requirements of this NFPA document and is included for informational purposes only. This informative annex is informative unless specifically adopted by the local jurisdiction adopting the National Electrical Code®.*

### Contents

- 80.1 Scope

- 80.29 Liability for Damages
- 80.31 Validity
- 80.33 Repeal of Conflicting Acts
- 80.35 Effective Date

Informative Annex H is a model set of rules for adoption by jurisdictions, in whole or in part, to administer an electrical inspection program. However, unless specifically adopted

by a governmental or other entity charged with enforcing electrical installation requirements, the material is advisory only. This informative annex first appeared as Article 80 of the 2002 *Code*.

The purpose of these administrative rules is to provide jurisdictions without a formalized electrical inspection and code adoption procedure with a template that can be used verbatim or with amendments tailored to fit that jurisdiction's needs. The information contained in the informative annex may also be used to augment or modify existing administrative rules. It provides an inspection process covering plan review, issuance of permits, number and types of inspections, and connection to or disconnection from the electrical supply system. Processes to file and adjudicate appeals and to adopt the current edition of the *Code* are provided. In addition, requirements for qualified electrical inspection personnel and for establishing an electrical board are provided.

Informative Annex H, Article 80, has an interesting history. Originally it was a model law that provided for inspection of electrical installations. It was prepared by the NFPA Electrical Field Service Advisory Committee to serve as a guide for those jurisdictions that either did not have formalized electrical inspection procedures or wanted to amend their electrical inspection laws, in addition to serving as a guide for adopting the *NEC*. The model law was intended for use by states as well as municipalities. The first edition of NFPA 70L, *Model State Law, Inspection of Electrical Installations*, was adopted by NFPA on May 15, 1973, and a second edition was approved on March 27, 1987.

For most political subdivisions, adoption of the *NEC* can occur in two ways. It can be incorporated in a law, or a law can be enacted authorizing a governmental agency or board to adopt it. Rule-making and legislative processes in a particular jurisdiction determine which alternative is more appropriate. Provisions that are less comprehensive may be adequate for smaller political subdivisions.

## 80.1 Scope.

The following functions are covered:

- (1) The inspection of electrical installations as covered by 90.2
- (2) The investigation of fires caused by electrical installations
- (3) The review of construction plans, drawings, and specifications for electrical systems
- (4) The design, alteration, modification, construction, maintenance, and testing of electrical systems and equipment
- (5) The regulation and control of electrical installations at special events including but not limited to exhibits, trade shows, amusement parks, and other similar special occupancies

## 80.2 Definitions.

**Authority Having Jurisdiction.** The organization, office, or individual responsible for approving equipment, materials, an installation, or a procedure.

**Chief Electrical Inspector.** An electrical inspector who either is the authority having jurisdiction or is designated by the authority having jurisdiction and is responsible for administering the requirements of this *Code*.

**Electrical Inspector.** An individual meeting the requirements of 80.27 and authorized to perform electrical inspections.

## 80.3 Purpose.

The purpose of this article shall be to provide requirements for administration and enforcement of the *National Electrical Code*.

## 80.5 Adoption.

Article 80 shall not apply unless specifically adopted by the local jurisdiction adopting the *National Electrical Code*.

## 80.7 Title.

The title of this *Code* shall be NFPA 70, *National Electrical Code*®, of the National Fire Protection Association. The short title of this *Code* shall be the *NEC*®.

## 80.9 Application.

**(A) New Installations.** This *Code* applies to new installations. Buildings with construction permits dated after adoption of this *Code* shall comply with its requirements.

**(B) Existing Installations.** Existing electrical installations that do not comply with the provisions of this *Code* shall be permitted to be continued in use unless the authority having jurisdiction determines that the lack of conformity with this *Code* presents an imminent danger to occupants. Where changes are required for correction of hazards, a reasonable amount of time shall be given for compliance, depending on the degree of the hazard.

**(C) Additions, Alterations, or Repairs.** Additions, alterations, or repairs to any building, structure, or premises shall conform to that required of a new building without requiring the existing building to comply with all the requirements of this *Code*. Additions, alterations, installations, or repairs shall not cause an existing building to become unsafe or to adversely affect the performance of the building as determined by the authority having jurisdiction. Electrical wiring added to an existing service, feeder, or branch circuit shall not result in an installation that violates the provisions of the *Code* in force at the time the additions are made.

### 80.11 Occupancy of Building or Structure.

(A) **New Construction.** No newly constructed building shall be occupied in whole or in part in violation of the provisions of this *Code*.

(B) **Existing Buildings.** Existing buildings that are occupied at the time of adoption of this *Code* shall be permitted to remain in use provided the following conditions apply:

- (1) The occupancy classification remains unchanged
- (2) There exists no condition deemed hazardous to life or property that would constitute an imminent danger

### 80.13 Authority.

Where used in this article, the term *authority having jurisdiction* shall include the chief electrical inspector or other individuals designated by the governing body. This *Code* shall be administered and enforced by the authority having jurisdiction designated by the governing authority as follows.

- (1) The authority having jurisdiction shall be permitted to render interpretations of this *Code* in order to provide clarification to its requirements, as permitted by 90.4.
- (2) When the use of any electrical equipment or its installations is found to be dangerous to human life or property, the authority having jurisdiction shall be empowered to have the premises disconnected from its source of electric supply, as established by the Board. When such equipment or installation has been so condemned or disconnected, a notice shall be placed thereon listing the causes for the condemnation, the disconnection, or both, and the penalty under 80.23 for the unlawful use thereof. Written notice of such condemnation or disconnection and the causes therefor shall be given within 24 hours to the owners, the occupant, or both, of such building, structure, or premises. It shall be unlawful for any person to remove said notice, to reconnect the electrical equipment to its source of electric supply, or to use or permit to be used electric power in any such electrical equipment until such causes for the condemnation or disconnection have been remedied to the satisfaction of the inspection authorities.
- (3) The authority having jurisdiction shall be permitted to delegate to other qualified individuals such powers as necessary for the proper administration and enforcement of this *Code*.
- (4) Police, fire, and other enforcement agencies shall have authority to render necessary assistance in the enforcement of this *Code* when requested to do so by the authority having jurisdiction.
- (5) The authority having jurisdiction shall be authorized to inspect, at all reasonable times, any building or premises for dangerous or hazardous conditions or equipment as set forth in this *Code*. The authority having jurisdiction shall be permitted to order any person(s) to remove or remedy such dangerous or hazardous condition or equipment. Any person(s) failing to comply with such order shall be in violation of this *Code*.
- (6) Where the authority having jurisdiction deems that conditions hazardous to life and property exist, he or she shall be permitted to require that such hazardous conditions in violation of this *Code* be corrected.
- (7) To the full extent permitted by law, any authority having jurisdiction engaged in inspection work shall be authorized at all reasonable times to enter and examine any building, structure, or premises for the purpose of making electrical inspections. Before entering a premises, the authority having jurisdiction shall obtain the consent of the occupant thereof or obtain a court warrant authorizing entry for the purpose of inspection except in those instances where an emergency exists. As used in this section, *emergency* means circumstances that the authority having jurisdiction knows, or has reason to believe, exist and that reasonably can constitute immediate danger to persons or property.
- (8) Persons authorized to enter and inspect buildings, structures, and premises as herein set forth shall be identified by proper credentials issued by this governing authority.
- (9) Persons shall not interfere with an authority having jurisdiction carrying out any duties or functions prescribed by this *Code*.
- (10) Persons shall not use a badge, uniform, or other credentials to impersonate the authority having jurisdiction.
- (11) The authority having jurisdiction shall be permitted to investigate the cause, origin, and circumstances of any fire, explosion, or other hazardous condition.
- (12) The authority having jurisdiction shall be permitted to require plans and specifications to ensure compliance with this *Code*.
- (13) Whenever any installation subject to inspection prior to use is covered or concealed without having first been inspected, the authority having jurisdiction shall be permitted to require that such work be exposed for inspection. The authority having jurisdiction shall be notified when the installation is ready for inspection and shall conduct the inspection within \_\_\_\_ days.
- (14) The authority having jurisdiction shall be permitted to order the immediate evacuation of any occupied building deemed unsafe when such building has hazardous conditions that present imminent danger to building occupants.
- (15) The authority having jurisdiction shall be permitted to waive specific requirements in this *Code* or permit alternative methods where it is assured that equivalent

lent objectives can be achieved by establishing and maintaining effective safety. Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency and that the system, method, or device is approved for the intended purpose.

- (16) Each application for a waiver of a specific electrical requirement shall be filed with the authority having jurisdiction and shall be accompanied by such evidence, letters, statements, results of tests, or other supporting information as required to justify the request. The authority having jurisdiction shall keep a record of actions on such applications, and a signed copy of the authority having jurisdiction's decision shall be provided for the applicant.

### 80.15 Electrical Board.

**(A) Creation of the Electrical Board.** There is hereby created the Electrical Board of the \_\_\_\_\_ of \_\_\_\_\_, hereinafter designated as the Board.

**(B) Appointments.** Board members shall be appointed by the Governor with the advice and consent of the Senate (or by the Mayor with the advice and consent of the Council, or the equivalent).

- (1) Members of the Board shall be chosen in a manner to reflect a balanced representation of individuals or organizations. The Chair of the Board shall be elected by the Board membership.
- (2) The Chief Electrical Inspector in the jurisdiction adopting this Article authorized in (B)(3)(a) shall be the non-voting secretary of the Board. Where the Chief Electrical Inspector of a local municipality serves a Board at a state level, he or she shall be permitted to serve as a voting member of the Board.
- (3) The board shall consist of not fewer than five voting members. Board members shall be selected from the following:
  - a. Chief Electrical Inspector from a local government (for State Board only)
  - b. An electrical contractor operating in the jurisdiction
  - c. A licensed professional engineer engaged primarily in the design or maintenance of electrical installations
  - d. A journeyman electrician
- (4) Additional membership shall be selected from the following:
  - a. A master (supervising) electrician
  - b. The Fire Marshal (or Fire Chief)
  - c. A representative of the property/casualty insurance industry
  - d. A representative of an electric power utility operating in the jurisdiction

- e. A representative of electrical manufacturers primarily and actively engaged in producing materials, fittings, devices, appliances, luminaires, or apparatus used as part of or in connection with electrical installations
- f. A member of the labor organization that represents the primary electrical workforce
- g. A member from the public who is not affiliated with any other designated group
- h. A representative of a telecommunications utility operating in the jurisdiction

**(C) Terms.** Of the members first appointed, \_\_\_\_\_ shall be appointed for a term of 1 year, \_\_\_\_\_ for a term of 2 years, \_\_\_\_\_ for a term of 3 years, and \_\_\_\_\_ for a term of 4 years, and thereafter each appointment shall be for a term of 4 years or until a successor is appointed. The Chair of the Board shall be appointed for a term not to exceed \_\_\_\_\_ years.

**(D) Compensation.** Each appointed member shall receive the sum of \_\_\_\_\_ dollars (\$\_\_\_\_\_) for each day during which the member attends a meeting of the Board and, in addition thereto, shall be reimbursed for direct lodging, travel, and meal expenses as covered by policies and procedures established by the jurisdiction.

**(E) Quorum.** A quorum as established by the Board operating procedures shall be required to conduct Board business. The Board shall hold such meetings as necessary to carry out the purposes of Article 80. The Chair or a majority of the members of the Board shall have the authority to call meetings of the Board.

**(F) Duties.** It shall be the duty of the Board to perform the following:

- (1) Adopt the necessary rules and regulations to administer and enforce Article 80.
- (2) Establish qualifications of electrical inspectors.
- (3) Revoke or suspend the recognition of any inspector's certificate for the jurisdiction.
- (4) After advance notice of the public hearings and the execution of such hearings, as established by law, the Board is authorized to establish and update the provisions for the safety of electrical installations to conform to the current edition of the *National Electrical Code* (NFPA 70) and other nationally recognized safety standards for electrical installations.
- (5) Establish procedures for recognition of electrical safety standards and acceptance of equipment conforming to these standards.

**(G) Appeals.**

- (1) *Review of Decisions.* Any person, firm, or corporation may register an appeal with the Board for a review of any

decision of the Chief Electrical Inspector or of any Electrical Inspector, provided that such appeal is made in writing within fifteen (15) days after such person, firm, or corporation shall have been notified. Upon receipt of such appeal, said Board shall, if requested by the person making the appeal, hold a public hearing and proceed to determine whether the action of the Board, or of the Chief Electrical Inspector, or of the Electrical Inspector complies with this law and, within fifteen (15) days after receipt of the appeal or after holding the hearing, shall make a decision in accordance with its findings.

- (2) **Conditions.** Any person shall be permitted to appeal a decision of the authority having jurisdiction to the Board when it is claimed that any one or more of the following conditions exist:
  - a. The true intent of the codes or ordinances described in this *Code* has been incorrectly interpreted.
  - b. The provisions of the codes or ordinances do not fully apply.
  - c. A decision is unreasonable or arbitrary as it applies to alternatives or new materials.
- (3) **Submission of Appeals.** A written appeal, outlining the *Code* provision from which relief is sought and the remedy proposed, shall be submitted to the authority having jurisdiction within 15 calendar days of notification of violation.

**(H) Meetings and Records.** Meetings and records of the Board shall conform to the following:

- (1) Meetings of the Board shall be open to the public as required by law.
- (2) Records of meetings of the Board shall be available for review during normal business hours, as required by law.

## 80.17 Records and Reports.

The authority having jurisdiction shall retain records in accordance with (A) and (B).

**(A) Retention.** The authority having jurisdiction shall keep a record of all electrical inspections, including the date of such inspections and a summary of any violations found to exist, the date of the services of notices, and a record of the final disposition of all violations. All required records shall be maintained until their usefulness has been served or as otherwise required by law.

**(B) Availability.** A record of examinations, approvals, and variances granted shall be maintained by the authority having jurisdiction and shall be available for public review as prescribed by law during normal business hours.

## 80.19 Permits and Approvals.

Permits and approvals shall conform to (A) through (H).

### (A) Application.

- (1) Activity authorized by a permit issued under this *Code* shall be conducted by the permittee or the permittee's agents or employees in compliance with all requirements of this *Code* applicable thereto and in accordance with the approved plans and specifications. No permit issued under this *Code* shall be interpreted to justify a violation of any provision of this *Code* or any other applicable law or regulation. Any addition or alteration of approved plans or specifications shall be approved in advance by the authority having jurisdiction, as evidenced by the issuance of a new or amended permit.
- (2) A copy of the permit shall be posted or otherwise readily accessible at each work site or carried by the permit holder as specified by the authority having jurisdiction.

**(B) Content.** Permits shall be issued by the authority having jurisdiction and shall bear the name and signature of the authority having jurisdiction or that of the authority having jurisdiction's designated representative. In addition, the permit shall indicate the following:

- (1) Operation or activities for which the permit is issued
- (2) Address or location where the operation or activity is to be conducted
- (3) Name and address of the permittee
- (4) Permit number and date of issuance
- (5) Period of validity of the permit
- (6) Inspection requirements

**(C) Issuance of Permits.** The authority having jurisdiction shall be authorized to establish and issue permits, certificates, notices, and approvals, or orders pertaining to electrical safety hazards pursuant to 80.23, except that no permit shall be required to execute any of the classes of electrical work specified in the following:

- (1) Installation or replacement of equipment such as lamps and of electric utilization equipment approved for connection to suitable permanently installed receptacles. Replacement of flush or snap switches, fuses, lamp sockets, and receptacles, and other minor maintenance and repair work, such as replacing worn cords and tightening connections on a wiring device
- (2) The process of manufacturing, testing, servicing, or repairing electrical equipment or apparatus

**(D) Annual Permits.** In lieu of an individual permit for each installation or alteration, an annual permit shall, upon application, be issued to any person, firm, or corporation regularly employing one or more employees for the installation, alteration, and maintenance of electrical equipment in or on buildings or premises owned or occupied by the applicant for the permit. Upon application, an electrical contractor as agent for the owner or tenant shall be issued an

annual permit. The applicant shall keep records of all work done, and such records shall be transmitted periodically to the Electrical Inspector.

**(E) Fees.** Any political subdivision that has been provided for electrical inspection in accordance with the provisions of Article 80 may establish fees that shall be paid by the applicant for a permit before the permit is issued.

**(F) Inspection and Approvals.**

- (1) Upon the completion of any installation of electrical equipment that has been made under a permit other than an annual permit, it shall be the duty of the person, firm, or corporation making the installation to notify the Electrical Inspector having jurisdiction, who shall inspect the work within a reasonable time.
- (2) Where the Inspector finds the installation to be in conformity with the statutes of all applicable local ordinances and all rules and regulations, the Inspector shall issue to the person, firm, or corporation making the installation a certificate of approval, with duplicate copy for delivery to the owner, authorizing the connection to the supply of electricity and shall send written notice of such authorization to the supplier of electric service. When a certificate of temporary approval is issued authorizing the connection of an installation, such certificates shall be issued to expire at a time to be stated therein and shall be revocable by the Electrical Inspector for cause.
- (3) When any portion of the electrical installation within the jurisdiction of an Electrical Inspector is to be hidden from view by the permanent placement of parts of the building, the person, firm, or corporation installing the equipment shall notify the Electrical Inspector, and such equipment shall not be concealed until it has been approved by the Electrical Inspector or until \_\_\_\_ days have elapsed from the time of such notification, provided that on large installations, where the concealment of equipment proceeds continuously, the person, firm, or corporation installing the equipment shall give the Electrical Inspector due notice in advance, and inspections shall be made periodically during the progress of the work.
- (4) At regular intervals, the Electrical Inspector having jurisdiction shall visit all buildings and premises where work may be done under annual permits and shall inspect all electrical equipment installed under such permits since the date of the previous inspection. The Electrical Inspector shall issue a certificate of approval for such work as is found to be in conformity with the provisions of Article 80 and all applicable ordinances, orders, rules, and regulations, after payments of all required fees.

- (5) If, upon inspection, any installation is found not to be fully in conformity with the provisions of Article 80, and all applicable ordinances, rules, and regulations, the Inspector making the inspection shall at once forward to the person, firm, or corporation making the installation a written notice stating the defects that have been found to exist.

**(G) Revocation of Permits.** Revocation of permits shall conform to the following:

- (1) The authority having jurisdiction shall be permitted to revoke a permit or approval issued if any violation of this *Code* is found upon inspection or in case there have been any false statements or misrepresentations submitted in the application or plans on which the permit or approval was based.
- (2) Any attempt to defraud or otherwise deliberately or knowingly design, install, service, maintain, operate, sell, represent for sale, falsify records, reports, or applications, or other related activity in violation of the requirements prescribed by this *Code* shall be a violation of this *Code*. Such violations shall be cause for immediate suspension or revocation of any related licenses, certificates, or permits issued by this jurisdiction. In addition, any such violation shall be subject to any other criminal or civil penalties as available by the laws of this jurisdiction.
- (3) Revocation shall be constituted when the permittee is duly notified by the authority having jurisdiction.
- (4) Any person who engages in any business, operation, or occupation, or uses any premises, after the permit issued therefor has been suspended or revoked pursuant to the provisions of this *Code*, and before such suspended permit has been reinstated or a new permit issued, shall be in violation of this *Code*.
- (5) A permit shall be predicated upon compliance with the requirements of this *Code* and shall constitute written authority issued by the authority having jurisdiction to install electrical equipment. Any permit issued under this *Code* shall not take the place of any other license or permit required by other regulations or laws of this jurisdiction.
- (6) The authority having jurisdiction shall be permitted to require an inspection prior to the issuance of a permit.
- (7) A permit issued under this *Code* shall continue until revoked or for the period of time designated on the permit. The permit shall be issued to one person or business only and for the location or purpose described in the permit. Any change that affects any of the conditions of the permit shall require a new or amended permit.

**(H) Applications and Extensions.** Applications and extensions of permits shall conform to the following:

- (1) The authority having jurisdiction shall be permitted to grant an extension of the permit time period upon presentation by the permittee of a satisfactory reason for failure to start or complete the work or activity authorized by the permit.
- (2) Applications for permits shall be made to the authority having jurisdiction on forms provided by the jurisdiction and shall include the applicant's answers in full to inquiries set forth on such forms. Applications for permits shall be accompanied by such data as required by the authority having jurisdiction, such as plans and specifications, location, and so forth. Fees shall be determined as required by local laws.
- (3) The authority having jurisdiction shall review all applications submitted and issue permits as required. If an application for a permit is rejected by the authority having jurisdiction, the applicant shall be advised of the reasons for such rejection. Permits for activities requiring evidence of financial responsibility by the jurisdiction shall not be issued unless proof of required financial responsibility is furnished.

### 80.21 Plans Review.

Review of plans and specifications shall conform to (A) through (C).

**(A) Authority.** For new construction, modification, or rehabilitation, the authority having jurisdiction shall be permitted to review construction documents and drawings.

**(B) Responsibility of the Applicant.** It shall be the responsibility of the applicant to ensure the following:

- (1) The construction documents include all of the electrical requirements.
- (2) The construction documents and drawings are correct and in compliance with the applicable codes and standards.

**(C) Responsibility of the Authority Having Jurisdiction.** It shall be the responsibility of the authority having jurisdiction to promulgate rules that cover the following:

- (1) Review of construction documents and drawings shall be completed within established time frames for the purpose of acceptance or to provide reasons for nonacceptance.
- (2) Review and approval by the authority having jurisdiction shall not relieve the applicant of the responsibility of compliance with this *Code*.
- (3) Where field conditions necessitate any substantial change from the approved plan, the authority having jurisdiction shall be permitted to require that the corrected plans be submitted for approval.

### 80.23 Notice of Violations, Penalties.

Notice of violations and penalties shall conform to (A) and (B).

#### (A) Violations.

- (1) Whenever the authority having jurisdiction determines that there are violations of this *Code*, a written notice shall be issued to confirm such findings.
- (2) Any order or notice issued pursuant to this *Code* shall be served upon the owner, operator, occupant, or other person responsible for the condition or violation, either by personal service or mail or by delivering the same to, and leaving it with, some person of responsibility upon the premises. For unattended or abandoned locations, a copy of such order or notice shall be posted on the premises in a conspicuous place at or near the entrance to such premises and the order or notice shall be mailed by registered or certified mail, with return receipt requested, to the last known address of the owner, occupant, or both.

#### (B) Penalties.

- (1) Any person who fails to comply with the provisions of this *Code* or who fails to carry out an order made pursuant to this *Code* or violates any condition attached to a permit, approval, or certificate shall be subject to the penalties established by this jurisdiction.
- (2) Failure to comply with the time limits of an abatement notice or other corrective notice issued by the authority having jurisdiction shall result in each day that such violation continues being regarded as a new and separate offense.
- (3) Any person, firm, or corporation who shall willfully violate any of the applicable provisions of this article shall be guilty of a misdemeanor and, upon conviction thereof, shall be punished by a fine of not less than \_\_\_\_\_ dollars (\$\_\_\_\_\_) or more than \_\_\_\_\_ dollars (\$\_\_\_\_\_) for each offense, together with the costs of prosecution, imprisonment, or both, for not less than \_\_\_\_\_ (\_\_\_\_\_) days or more than \_\_\_\_\_ (\_\_\_\_\_) days.

### 80.25 Connection to Electricity Supply.

Connections to the electric supply shall conform to (A) through (E).

**(A) Authorization.** Except where work is done under an annual permit and except as otherwise provided in 80.25, it shall be unlawful for any person, firm, or corporation to make connection to a supply of electricity or to supply electricity to any electrical equipment installation for which a permit is required or that has been disconnected or ordered to be disconnected.

**(B) Special Consideration.** By special permission of the authority having jurisdiction, temporary power shall be permitted to be supplied to the premises for specific needs of the construction project. The Board shall determine what needs are permitted under this provision.

**(C) Notification.** If, within \_\_\_\_\_ business days after the Electrical Inspector is notified of the completion of an installation of electric equipment, other than a temporary approval installation, the Electrical Inspector has neither authorized connection nor disapproved the installation, the supplier of electricity is authorized to make connections and supply electricity to such installation.

**(D) Other Territories.** If an installation or electric equipment is located in any territory where an Electrical Inspector has not been authorized or is not required to make inspections, the supplier of electricity is authorized to make connections and supply electricity to such installations.

**(E) Disconnection.** Where a connection is made to an installation that has not been inspected, as outlined in the preceding paragraphs of this section, the supplier of electricity shall immediately report such connection to the Chief Electrical Inspector. If, upon subsequent inspection, it is found that the installation is not in conformity with the provisions of Article 80, the Chief Electrical Inspector shall notify the person, firm, or corporation making the installation to rectify the defects and, if such work is not completed within fifteen (15) business days or a longer period as may be specified by the Board, the Board shall have the authority to cause the disconnection of that portion of the installation that is not in conformity.

### 80.27 Inspector's Qualifications.

**(A) Certificate.** All electrical inspectors shall be certified by a nationally recognized inspector certification program accepted by the Board. The certification program shall specifically qualify the inspector in electrical inspections. No person shall be employed as an Electrical Inspector unless that person is the holder of an Electrical Inspector's certificate of qualification issued by the Board, except that any person who on the date on which this law went into effect was serving as a legally appointed Electrical Inspector of \_\_\_\_\_ shall, upon application and payment of the prescribed fee and without examination, be issued a special certificate permitting him or her to continue to serve as an Electrical Inspector in the same territory.

**(B) Experience.** Electrical inspector applicants shall demonstrate the following:

- (1) Have a demonstrated knowledge of the standard materials and methods used in the installation of electric equipment
- (2) Be well versed in the approved methods of construction for safety to persons and property
- (3) Be well versed in the statutes of \_\_\_\_\_ relating to electrical work and the *National Electrical Code*, as approved by the American National Standards Institute
- (4) Have had at least \_\_\_\_\_ years' experience as an Electrical Inspector or \_\_\_\_\_ years in the installation of electrical equipment. In lieu of such experience, the applicant shall be a graduate in electrical engineering or of a similar curriculum of a college or university considered by the Board as having suitable requirements for graduation and shall have had two years' practical electrical experience.

**(C) Recertification.** Electrical inspectors shall be recertified as established by provisions of the applicable certification program.

**(D) Revocation and Suspension of Authority.** The Board shall have the authority to revoke an inspector's authority to conduct inspections within a jurisdiction.

### 80.29 Liability for Damages.

Article 80 shall not be construed to affect the responsibility or liability of any party owning, designing, operating, controlling, or installing any electrical equipment for damages to persons or property caused by a defect therein, nor shall the \_\_\_\_\_ or any of its employees be held as assuming any such liability by reason of the inspection, reinspection, or other examination authorized.

### 80.31 Validity.

If any section, subsection, sentence, clause, or phrase of Article 80 is for any reason held to be unconstitutional, such decision shall not affect the validity of the remaining portions of Article 80.

### 80.33 Repeal of Conflicting Acts.

All acts or parts of acts in conflict with the provisions of Article 80 are hereby repealed.

### 80.35 Effective Date.

Article 80 shall take effect \_\_\_\_\_ (\_\_\_\_\_) days after its passage and publication.

# Informative Annex

## Recommended Tightening Torque Tables from UL Standard 486A-B

*This informative annex is not a part of the requirements of this NFPA document, but is included for informational purposes only.*

In the absence of connector or equipment manufacturer's recommended torque values, Table I.1, Table I.2, and Table I.3 may be used to correctly tighten screw-type connections for power and lighting circuits\*. Control and signal

circuits may require different torque values, and the manufacturer should be contacted for guidance.

\*For proper termination of conductors, it is very important that field connections be properly tightened. In the ab-

**TABLE I.1 Tightening Torque for Screws**

Test Conductor Installed in Connector		Tightening Torque, N-m (lbf-in.)							
		Slotted head No. 10 and larger <sup>a</sup>				Hexagonal head — external drive socket wrench			
		Slot width 1.2 mm (0.047 in.) or less and slot length 6.4 mm (¼ in.) or less		Slot width over 1.2 mm (0.047 in.) or slot length over 8.4 mm (1.4 in.)		Split-bolt connectors		Other connectors	
		A	B	A	B	A	B	A	B
AWG or kcmil	mm <sup>2</sup>								
30–10	0.05–5.3	1.7 (15)	2.3 (20)	2.8 (25)	4.0 (35)	7.3 (65)	9.0 (80)	6.8 (60)	8.5 (75)
8	8.4	2.3 (20)	2.8 (25)	3.4 (30)	4.5 (40)	7.3 (65)	9.0 (80)	6.8 (60)	8.5 (75)
6–4	13.2–21.2	2.8 (25)	4.0 (35)	4.0 (35)	5.1 (45)	15.3 (135)	18.5 (165)	10.2 (90)	12.4 (110)
3	26.7	2.8 (25)	4.0 (35)	4.5 (40)	5.6 (50)	25.4 (225)	31.1 (275)	14.1 (125)	16.9 (150)
2	33.6	3.4 (30)	4.5 (40)	4.5 (40)	5.6 (50)	25.4 (225)	31.1 (275)	14.1 (125)	16.9 (150)
1	42.4	—	—	4.5 (40)	5.6 (50)	25.4 (225)	31.1 (275)	14.1 (125)	16.9 (150)
1/0–2/0	53.5–67.4	—	—	4.5 (40)	5.6 (50)	35.6 (315)	43.5 (385)	16.9 (150)	20.3 (180)
3/0–4/0	85.0–107.2	—	—	4.5 (40)	5.6 (50)	45.2 (400)	56.5 (500)	22.6 (200)	28.2 (250)
250–350	127–177	—	—	4.5 (40)	5.6 (50)	62.1 (550)	73.4 (650)	28.2 (250)	36.7 (325)
400	203	—	—	4.5 (40)	5.6 (50)	76.3 (675)	93.2 (825)	28.2 (250)	36.7 (325)
500	253	—	—	4.5 (40)	5.6 (50)	76.3 (675)	93.2 (825)	33.9 (300)	42.4 (375)
600–750	304–380	—	—	4.5 (40)	5.6 (50)	90.4 (800)	113.0 (1000)	33.9 (300)	42.4 (375)
800–1000	405–508	—	—	4.5 (40)	5.6 (50)	111.7 (900)	124.3 (1100)	45.2 (400)	56.5 (500)
1250–2000	635–1010	—	—	—	—	111.7 (900)	124.3 (1100)	56.5 (500)	67.8 (600)

<sup>a</sup>For values of slot width or length not corresponding to those specified, select the largest torque value associated with the conductor size. Slot width is the nominal design value. Slot length shall be measured at the bottom of the slot.

**TABLE I.2 Tightening Torque for Slotted Head Screws Smaller Than No. 10 Intended for Use with 8 AWG (8.4 mm<sup>2</sup>) or Smaller Conductors**

Slot Length of Screw <sup>a</sup>		Tightening Torque, N-m (lbf-in.)			
		Slot width of screw smaller than 1.2 mm (0.047 in.) <sup>b</sup>		Slot width of screw 1.2 mm (0.047 in.) and larger <sup>b</sup>	
mm	in.	A	B	A	B
Less than 4	Less than 5/32	0.68 (6)	0.79 (7)	0.79 (7)	1.0 (9)
4	5/32	0.68 (6)	0.79 (7)	1.1 (10)	1.4 (12)
4.8	3/16	0.68 (6)	0.79 (7)	1.1 (10)	1.4 (12)
5.5	7/32	0.68 (6)	0.79 (7)	1.1 (10)	1.4 (12)
6.4	1/4	0.79 (7)	1.0 (9)	1.1 (10)	1.4 (12)
7.1	9/32			1.4 (12)	1.7 (15)
Above 7.1	Above 9/32			1.8 (15)	2.3 (20)

<sup>a</sup>For slot lengths of intermediate values, select torques pertaining to next shorter slot lengths. Also, see 9.1.9.6 of UL 486A-B-2003 for screws with multiple tightening means. Slot length shall be measured at the bottom of the slot.

<sup>b</sup>Slot width is the nominal design value.

**TABLE I.3 Tightening Torque for Screws with Recessed Allen or Square Drives**

Socket Width Across Flats <sup>a</sup>		Tightening Torque, N-m (lbf-in.)			
mm	in.	A		B	
3.2	1/8	4.0	(35)	5.1	(45)
4.0	5/32	9.0	(80)	11.3	(100)
4.8	3/16	11.3	(100)	13.5	(120)
5.5	7/32	13.5	(120)	16.9	(150)
6.4	1/4	16.9	(150)	22.5	(200)
7.9	5/16	25.4	(225)	31.1	(275)
9.5	3/8	33.9	(300)	42.4	(375)
12.7	1/2	45.2	(400)	56.5	(500)
14.3	9/16	56.5	(500)	67.8	(600)

<sup>a</sup>See 9.1.9.6 of UL 486A-B-2003 for screws with multiple tightening means.

With the permission of Underwriters Laboratories, Inc., material is reproduced from UL Standard 486A-B, Wire Connectors, which is copyrighted by Underwriters Laboratories, Inc., Northbrook, Illinois. While use of this material has been authorized, UL shall not be responsible for the manner in which the information is presented, nor for any interpretations thereof. For more information on UL or to purchase standards, please visit our Standards website at [www.comm-2000.com](http://www.comm-2000.com) or call 1-888-853-3503.

sence of manufacturer's instructions on the equipment, the torque values given in these tables are recommended. Because it is normal for some relaxation to occur in service,

checking torque values sometime after installation is not a reliable means of determining the values of torque applied at installation.

Definition, 100–I

High

Definition, 490.2

Less than 50, Art. 720

Limitations, elevators, dumbwaiters, escalators, moving walks, 620.3

Low

Definition, 551.2

Marking, 240.83(E)

Nominal

Definition, 100–I

Nominal battery

Definition, 480.2

Over 600 volts, Art. 490

Receptacles, voltages between adjacent, 406.5(G)

Small wind electric systems, 694.66

Swimming pool underwater luminaires, 680.23(A)(4)

Wiring methods, 300.2

## W

**Wading pools**

Definition, 680.2

**Wall-mounted ovens** *see* Ovens, wall-mounted

**Warning signs (labels), at equipment;** *see also* Labels required

Aircraft hangars, 513.7(F), 513.10

Arc-flash hazard warning, 110.16

Electroplating, 669.7

Electrostatic hand spraying, 516.10(A)(8)

Elevators, dumbwaiters, escalators, moving walks, platform lifts, and stairway chairlifts, 620.3(A), 620.52(B)

Emergency systems, 700.7(B)

Fuel cell systems, 692.10(C), 692.17, 692.56

Guarding live parts 600 volts or less, 110.27(C)

Induction and dielectric heating, 665.23

Legally required standby systems, 701.7(B)

Locked room or enclosure with live parts over 600 volts, 110.34(C), 490.21(B)(7) Ex., 490.21(C)(2), 490.21(E), 490.44(B), 490.53, 490.55

Optional standby systems, 702.7(B)

Small wind electric systems, 694.18(C), 694.22(A)

Solar photovoltaic systems, 690.5(C), 690.10(C), 690.17, 690.35(F)

Switchboards or panels, 408.3(F)

Transformers, 450.8(D)

Utility interactive inverters, 705.12(D)(7)

**Water, natural and artificially made bodies of** *see* Natural and artificially made bodies of water, electrical wiring and equipment for

**Water heaters,** 422.11(E), 422.11(F)(3), 422.13

Controls, 422.47

Protection, 422.11(E), 422.11(F)(3)

**Water pipe**

Bonding (metal), 250.104

Connections, 250.68

As grounding electrode, 250.52(A)(1), 250.53(D)

**Watertight**

Definition, 100–I

**Weatherproof**

Definition, 100–I

**Welders, electric**, Art. 630

Arc, 630–II

Resistance, 630–III

Welding cable, 630–IV

**Wet locations**; *see also* Damp or wet locations

Conductors, types, 310.10(C), Table 310.104(A)

Control circuits in, 522.28

Definition, 100–I

Electrical metallic tubing, 358.10(C)

Electric signs and outline lighting, 600.9(D), 600.21(C), 600.33(A)(1), 600.42(G)(2), 600.42(H)(2)

Enameled equipment, 300.6(A)(1)

Ground-fault circuit interrupters, 210.8(B)(6)

Gutters, sheet metal auxiliary, 366.10(A)(2)

Health care facilities, 517.20

Intermediate metal conduit, 342.10(D)

Lampholders in, 410.96

Luminaires in, 410.10(A), 410.30(B)(1)

Mounting of equipment, 300.6(D)

Nonmetallic wireways, 378.10(3)

**Raceways**

Above grade locations, installed in, 300.9

Exterior surfaces of buildings, on, 225.22

Recreational vehicle parks, 551.78(A)

Reinforcing thermosetting resin conduit, 355.10(D)

Rigid metal conduit, 344.10(D)

Rigid polyvinyl chloride conduit, 352.10(D)

Underground locations as, 300.5(B)

**Wet procedure locations**

Health care facilities, 517.20

Definition, 517.2

**Wind electric systems, small**, Art. 694

Circuit requirements, 694–II

Connection to other sources, 694–VII

Definitions, 694.2

Disconnecting means, 694–III, 694.70(F)

Grounding, 694–V

Installation, 694.7, 694.28, 694.62, 694.70

Markings, 694.22(C)(2), 694–VI

Overcurrent protection, 694.12(B), 694.15

Over 600 volts, 694–IX

Stand-alone systems, 694.12(A)(3), 694.18, 694.54

Storage batteries, 694–VIII

Wiring methods, 694–IV

## IMPORTANT NOTICES AND DISCLAIMERS CONCERNING NFPA® DOCUMENTS

### NOTICE AND DISCLAIMER OF LIABILITY CONCERNING THE USE OF NFPA DOCUMENTS

NFPA® codes, standards, recommended practices, and guides (“NFPA Documents”), of which the NFPA Document contained herein is one, are developed through a consensus standards development process approved by the American National Standards Institute. This process brings together volunteers representing varied viewpoints and interests to achieve consensus on fire and other safety issues. While the NFPA administers the process and establishes rules to promote fairness in the development of consensus, it does not independently test, evaluate, or verify the accuracy of any information or the soundness of any judgments contained in NFPA Documents.

The NFPA disclaims liability for any personal injury, property or other damages of any nature whatsoever, whether special, indirect, consequential or compensatory, directly or indirectly resulting from the publication, use of, or reliance on NFPA Documents. The NFPA also makes no guaranty or warranty as to the accuracy or completeness of any information published herein.

In issuing and making NFPA Documents available, the NFPA is not undertaking to render professional or other services for or on behalf of any person or entity. Nor is the NFPA undertaking to perform any duty owed by any person or entity to someone else. Anyone using this document should rely on his or her own independent judgment or, as appropriate, seek the advice of a competent professional in determining the exercise of reasonable care in any given circumstances.

The NFPA has no power, nor does it undertake, to police or enforce compliance with the contents of NFPA Documents. Nor does the NFPA list, certify, test, or inspect products, designs, or installations for compliance with this document. Any certification or other statement of compliance with the requirements of this document shall not be attributable to the NFPA and is solely the responsibility of the certifier or maker of the statement.

### ADDITIONAL NOTICES AND DISCLAIMERS

#### Updating of NFPA Documents

Users of NFPA codes, standards, recommended practices, and guides (“NFPA Documents”) should be aware that these documents may be superseded at any time by the issuance of new editions or may be amended from time to time through the issuance of Tentative Interim Amendments. An official NFPA Document at any point in time consists of the current edition of the document together with any Tentative Interim Amendments and any Errata then in effect. In order to determine whether a given document is the current edition and whether it has been amended through the issuance of Tentative Interim Amendments or corrected through the issuance of Errata, consult appropriate NFPA publications such as the National Fire Codes® Subscription Service, visit the NFPA website at [www.nfpa.org](http://www.nfpa.org), or contact the NFPA at the address listed below.

#### Interpretations of NFPA Documents

A statement, written or oral, that is not processed in accordance with Section 6 of the Regulations Governing Committee Projects shall not be considered the official position of NFPA or any of its Committees and shall not be considered to be, nor be relied upon as, a Formal Interpretation.

#### Patents

The NFPA does not take any position with respect to the validity of any patent rights referenced in, related to, or asserted in connection

with an NFPA Document. The users of NFPA Documents bear the sole responsibility for determining the validity of any such patent rights, as well as the risk of infringement of such rights, and the NFPA disclaims liability for the infringement of any patent resulting from the use of or reliance on NFPA Documents.

NFPA adheres to the policy of the American National Standards Institute (ANSI) regarding the inclusion of patents in American National Standards (“the ANSI Patent Policy”), and hereby gives the following notice pursuant to that policy:

**NOTICE:** The user’s attention is called to the possibility that compliance with an NFPA Document may require use of an invention covered by patent rights. NFPA takes no position as to the validity of any such patent rights or as to whether such patent rights constitute or include essential patent claims under the ANSI Patent Policy. If, in connection with the ANSI Patent Policy, a patent holder has filed a statement of willingness to grant licenses under these rights on reasonable and nondiscriminatory terms and conditions to applicants desiring to obtain such a license, copies of such filed statements can be obtained, on request, from NFPA. For further information, contact the NFPA at the address listed below.

#### Law and Regulations

Users of NFPA Documents should consult applicable federal, state, and local laws and regulations. NFPA does not, by the publication of its codes, standards, recommended practices, and guides, intend to urge action that is not in compliance with applicable laws, and these documents may not be construed as doing so.

#### Copyrights

NFPA Documents are copyrighted by the NFPA. They are made available for a wide variety of both public and private uses. These include both use, by reference, in laws and regulations, and use in private self-regulation, standardization, and the promotion of safe practices and methods. By making these documents available for use and adoption by public authorities and private users, the NFPA does not waive any rights in copyright to these documents.

Use of NFPA Documents for regulatory purposes should be accomplished through adoption by reference. The term “adoption by reference” means the citing of title, edition, and publishing information only. Any deletions, additions, and changes desired by the adopting authority should be noted separately in the adopting instrument. In order to assist NFPA in following the uses made of its documents, adopting authorities are requested to notify the NFPA (Attention: Secretary, Standards Council) in writing of such use. For technical assistance and questions concerning adoption of NFPA Documents, contact NFPA at the address below.

#### For Further Information

All questions or other communications relating to NFPA Documents and all requests for information on NFPA procedures governing its codes and standards development process, including information on the procedures for requesting Formal Interpretations, for proposing Tentative Interim Amendments, and for proposing revisions to NFPA documents during regular revision cycles, should be sent to NFPA headquarters, addressed to the attention of the Secretary, Standards Council, NFPA, 1 Batterymarch Park, P.O. Box 9101, Quincy, MA 02269-9101; email: [stds\\_admin@nfpa.org](mailto:stds_admin@nfpa.org)

For more information about NFPA, visit the NFPA website at [www.nfpa.org](http://www.nfpa.org).
